bring λ into coincidence with c since they are both determined by the same constant C , and naturally the rotated curve λ is still a geodesic. In other words, we have shown that c eventually hits δ . Moreover, c' points along δ' at the intersection point (as it must, since $r(t) \cdot \sin \alpha(t) = C$). In addition, c must bounce off δ and proceed downwards. Naturally, the shape of the part going downwards must differ from that of the part going upwards only by a reflection.

ADDENDUM 1

SPECIAL PARAMETER CURVES

Proposition I.5-18 immediately implies

17. COROLLARY. Let p be a point on a surface M in \mathbb{R}^3 .

(a) If p is not an umbilic point, then there is an imbedding $f: U \rightarrow M$, with $p \in f(U)$, whose parameter curves are lines of curvature.

(b) If $K(p) < 0$, then there is an imbedding $f: U \rightarrow M$, with $p \in f(U)$, whose parameter curves are asymptotic curves.

It is sometime useful, especially in the next chapter, to write some of our formulas in terms of these and other special coordinate systems; readers may check for themselves that the following formulas are correct.

A. *The parameter lines are orthogonal.*

Then $F = 0$, and the formula in Problem 13 becomes (subscripts denoting partial derivatives)

$$K = -\frac{1}{2\sqrt{EG}} \left[\left(\frac{E_2}{\sqrt{EG}} \right)_2 + \left(\frac{G_1}{\sqrt{EG}} \right)_1 \right].$$

B. *The parameter lines are lines of curvature.*

In this case, of course, we still have the equation from (A). We also have

$$l = k_1 E, \quad n = k_2 G, \quad m = 0, \quad F = 0.$$

So the Codazzi-Mainardi equations (page 56) become

$$l_2 = \frac{E_2}{2} \left(\frac{l}{E} + \frac{n}{G} \right)$$

$$n_1 = \frac{G_1}{2} \left(\frac{l}{E} + \frac{n}{G} \right).$$

C. *The parameter lines are asymptotic curves.*

We have $l = n = 0$, and the Codazzi-Mainardi equations become

$$m_1 = \frac{\left[\frac{1}{2}(EG - F^2)_1 + FE_2 - EG_1 \right]}{EG - F^2} \cdot m$$

$$m_2 = \frac{\left[\frac{1}{2}(EG - F^2)_2 + FG_1 - GE_2 \right]}{EG - F^2} \cdot m.$$

ADDENDUM 2

SINGULARITIES OF LINE FIELDS

In Chapter I.11 we defined the index of an isolated zero of a vector field, and we proved (Theorem I.11-30) that if a vector field on a compact oriented manifold M has only isolated zeros, then the sum of the indices of these zeros is the Euler characteristic of M .

Now consider the situation where we have a 1-dimensional distribution Δ defined in a neighborhood of a point p of a 2-dimensional manifold M , except at the point p itself. As is easily seen from the pictures below, it may not be

possible to find a nowhere zero vector field X such that $\Delta(q)$ is always spanned by $X(q)$. Nevertheless, we will define an index of Δ at p .

As in the case of a vector field, we first suppose that the distribution Δ is defined on $U - \{0\}$, for U a neighborhood of $0 \in \mathbb{R}^2$. We introduce the projective line \mathbb{P}^1 , which is S^1 with all pairs of antipodal points x and $-x$ identified. Alternatively, \mathbb{P}^1 is the set of all lines through $0 \in \mathbb{R}^2$, and thus the set of all directions in \mathbb{R}^2 . Then we have a map $f_\Delta: U - \{0\} \rightarrow \mathbb{P}^1$ defined by $f_\Delta(q) =$ the direction of $\Delta(q)$. If we let $i: S^1 \rightarrow U$ be $i(x) = \varepsilon x$ for some $\varepsilon > 0$, then we have the map $f_\Delta \circ i: S^1 \rightarrow \mathbb{P}^1$. But \mathbb{P}^1 is homeomorphic to S^1 —we can define a homeomorphism $\alpha: \mathbb{P}^1 \rightarrow S^1$ by noting that \mathbb{P}^1 is the same as a semi-circle with end points identified. Thus we have a map

$$\alpha \circ f_\Delta \circ i: S^1 \rightarrow S^1,$$

and this map has a certain degree. We define the **index** of Δ at p to be

$$\text{index of } \Delta \text{ at } p = \frac{1}{2} \text{degree}(\alpha \circ f_\Delta \circ i).$$

The same arguments which we used in Chapter I.11 allow us to extend this definition from \mathbb{R}^2 to any arbitrary surface. Some examples of these indices are given below.

If Δ happens to be of the form $\Delta(q) = \text{space spanned by } X(q)$, for a vector field X , and $f_X: U - \{0\} \rightarrow S^1$ is the map taking q to $X(q)/|X(q)| \in S^1$, then we have the commutative diagram

$$\begin{array}{ccc}
 S^1 & \xrightarrow{f_X \circ i} & S^1 \\
 & \searrow f_\Delta \circ i & \downarrow \pi \\
 & & \mathbb{P}^1 \\
 & & \downarrow \alpha \\
 & & S^1
 \end{array}$$

where π is the natural projection. Since $\alpha \circ \pi: S^1 \rightarrow S^1$ has degree 2, it follows

that we have

$$\begin{aligned}
 \text{index of } \Delta \text{ at } p &= \frac{1}{2} \text{degree}(\alpha \circ f_{\Delta} \circ i) \\
 &= \frac{1}{2} \text{degree}(\alpha \circ \pi \circ f_X \circ i) \\
 &= \text{degree}(f_X \circ i) \\
 &= \text{index of } X \text{ at } p.
 \end{aligned}$$

In particular, the index of Δ at p is an integer in this case.

Conversely, if the index of Δ at p is an integer, then a suitable vector field X can be found. The easiest way to see this is to give an alternative description of the index. Let $c: [0, 1] \rightarrow \mathbb{R}^2$ be the curve $c(t) = \varepsilon(\cos 2\pi t, \sin 2\pi t)$. The angle between the x -axis and the direction of $\Delta(q)$ is defined only up to a multiple of π [while the angle between the x -axis and a vector is defined only up to a multiple of 2π], but we can find a continuous function $\theta: [0, 1] \rightarrow \mathbb{R}$ such that $\theta(t)$ is an angle between the x -axis and the direction of $\Delta(c(t))$. Then (compare Proposition II.1-6) we have

$$\text{index of } \Delta \text{ at } p = \frac{1}{2\pi}[\theta(1) - \theta(0)].$$

If this index is an integer, so that $\theta(1) - \theta(0)$ is a multiple of 2π , then we can pick out X along c by letting $X(c(t))$ be the unit vector in $\Delta(c(t))$ such that $\theta(t)$ is an angle between $X(c(t))$ and the x -axis.

Given any 1-dimensional distribution Δ defined in $M - \{p_1, \dots, p_k\}$, we can define a 2-fold covering space $\varpi: M' \rightarrow M - \{p_1, \dots, p_k\}$ just as on page 198: we let the two points of $\varpi^{-1}(q)$ correspond to the two unit vectors in $\Delta(q)$. If U is an open ball around p_i , then $\varpi^{-1}(U)$ is either two disjoint copies of $U - \{p\}$, or else it is connected and $\varpi|_{\varpi^{-1}(U)}$ looks like the map $z \mapsto z^2$ taking

$$\{z \in \mathbb{C} : 0 < |z| < 1\} \rightarrow \{z \in \mathbb{C} : 0 < |z| < 1\}.$$

The first case occurs when Δ comes from a vector field, and the second case occurs when it does not. In the former case, we will add two new points to M' , one for each of the disjoint copies of $U - \{p_i\}$, define ϖ of each of these two new points to be p_i , and define the neighborhoods of these new points in the obvious way so that $\varpi^{-1}(U)$ now consists of two disjoint copies of U . In the second case, we will add just *one* new point p_i^* whose neighborhoods we define to be the sets $\{p_i^*\} \cup \varpi^{-1}(A - \{p_i\})$ for A a neighborhood of p_i in U . Let \tilde{M} be M' with all new points added. Then \tilde{M} is a manifold, but the map

$\varpi: \tilde{M} \rightarrow M$ is not a 2-fold covering space, for over certain points p_i it looks like the map $z \mapsto z^2$. These points p_i are called “branch points” of the 2-fold “branched covering space” $\varpi: \tilde{M} \rightarrow M$. There is clearly a distribution $\tilde{\Delta}$ on $\varpi^{-1}(M - \{p_1, \dots, p_k\})$ with $\varpi_*\tilde{\Delta} = \Delta$; moreover $\tilde{\Delta}$ obviously comes from a vector field.

If our original Δ looks like

in a neighborhood U of p_i , then $\tilde{\Delta}$ looks something like

(to see this, just note that if we wrap the bottom pictures twice around the origin, by $z \mapsto z^2$, then the images cover the top pictures). In general,

18. LEMMA. Let $\varpi: \tilde{M} \rightarrow M$ be a 2-fold branched covering space, and let p be a branch point. Let Δ be a 1-dimensional distribution defined on a neighborhood of p , except at p itself, and let $\tilde{\Delta}$ be a 1-dimensional distribution defined on a neighborhood of $\varpi^{-1}(p)$, except at $\varpi^{-1}(p)$ itself, such that $\varpi_*\tilde{\Delta} = \Delta$. Then the index \tilde{i} of $\tilde{\Delta}$ at $\varpi^{-1}(p)$ is related to the index i of Δ at p by

$$\tilde{i} = 2i - 1.$$

PROOF. Regard both p and $\varpi^{-1}(p)$ as $0 \in \mathbb{C}$, and ϖ as the map $z \mapsto z^2$. Let $c: [0, 1] \rightarrow \mathbb{R}^2$ be the semi-circle $c(t) = \varepsilon(\cos \pi t, \sin \pi t)$, and let $\theta: [0, 1] \rightarrow \mathbb{R}$ be a continuous function such that $\theta(t)$ is an angle between the x -axis and the direction of $\tilde{\Delta}(c(t))$. Note that by our construction of $\tilde{\Delta}$ we have

$$\tilde{i} = 2 \cdot \frac{1}{2\pi} [\theta(1) - \theta(0)].$$

Now the curve $\varpi \circ c: [0, 1] \rightarrow \mathbb{R}^2$ is the circle

$$\varpi \circ c(t) = \varepsilon^2(\cos 2\pi t, \sin 2\pi t).$$

It is easy to see that the function

$$\phi(t) = \theta(t) + \pi t$$

gives an angle between the x -axis and the direction of $\Delta(\varpi \circ c(t))$. So

$$\begin{aligned} i &= \frac{1}{2\pi}[\phi(1) - \phi(0)] = \frac{1}{2\pi}[\theta(1) - \theta(0)] + \frac{1}{2} \\ &= \frac{\tilde{i}}{2} + \frac{1}{2}. \quad \blacklozenge \end{aligned}$$

It is also easy to find the Euler characteristic $\chi(\tilde{M})$.

19. LEMMA. If $\varpi: \tilde{M} \rightarrow M$ is a 2-fold branched covering space with l branch points p_1, \dots, p_l , then

$$\chi(\tilde{M}) = 2\chi(M) - l.$$

FIRST PROOF. We will use a triangulation of M (Problem 17 suggests a simple proof that any compact surface can be triangulated). Choose the triangulation so that p_1, \dots, p_l are included among the V vertices (0-simplexes), and let there be E edges (1-simplexes) and F faces (2-simplexes). There is an obvious triangulation of \tilde{M} with 2 vertices over each vertex of M , except for the vertices p_1, \dots, p_l over which there is only 1 vertex. So the number \tilde{V} of vertices of \tilde{M} is

$$\tilde{V} = 2V - l,$$

while we have

$$\tilde{E} = 2E, \quad \tilde{F} = 2F.$$

So

$$\chi(\tilde{M}) = \tilde{V} - \tilde{E} + \tilde{F} = 2V - l - 2E + 2F = 2\chi(M) - l.$$

SECOND PROOF. Let X be a vector field on M with only finitely many zeros q_1, \dots, q_k , and let ι_j be the index of X at q_j . We might as well assume that the p_i are contained among the q 's, for at any point we can always introduce a new zero of X (with index 0). Then there is a vector field \tilde{X} on $\varpi^{-1}(M - \{q_1, \dots, q_k\})$ with $\varpi_*\tilde{X} = X$. If q_j is a branch point, then by Lemma 18,

$$\text{index of } \tilde{X} \text{ at } \varpi^{-1}(q_j) = 2\iota_j - 1.$$

If q_j is not a branch point, then $\varpi^{-1}(q_j)$ consists of two points q'_j, q''_j , and

$$\text{index of } \tilde{X} \text{ at } q'_j \text{ or } q''_j = \iota_j.$$

Then Theorem I.11-30 gives

$$\begin{aligned} \chi(\tilde{M}) &= \text{sum of the indices of } \tilde{X} \\ &= 2 \sum \iota_j - \text{number of branch points} \\ &= 2\chi(M) - l. \quad \spadesuit \end{aligned}$$

Exactly the same sort of reasoning which was used in this second proof leads us to our main result.

20. THEOREM. Let M be a compact oriented surface, and Δ a 1-dimensional distribution on $M - \{p_1, \dots, p_k\}$. Then the sum of the indices of Δ at the p_i is $\chi(M)$.

PROOF. Consider the 2-fold branched covering $\varpi: \tilde{M} \rightarrow M$ constructed previously, and the distribution $\tilde{\Delta}$ on \tilde{M} . If p_i is a branch point, then by Lemma 18

$$\text{index of } \tilde{\Delta} \text{ at } \varpi^{-1}(p_i) = 2(\text{index of } \Delta \text{ at } p_i) - 1.$$

If p_i is not a branch point, then $\varpi^{-1}(p_i)$ consists of two points p'_i, p''_i , and

$$\text{index of } \tilde{\Delta} \text{ at } p'_i \text{ or } p''_i = \text{index of } \Delta \text{ at } p_i.$$

It follows that

$$(1) \quad \begin{aligned} \text{sum of the indices of } \tilde{\Delta} &= 2(\text{sum of the indices of } \Delta) \\ &\quad - \text{number of branch points.} \end{aligned}$$

Since $\tilde{\Delta}$ comes from a vector field, it follows from Theorem I.11-30 that

$$(2) \quad \text{sum of the indices of } \tilde{\Delta} = \chi(\tilde{M}).$$

The result now follows from (1), (2), and Lemma 19. \spadesuit

PROBLEMS

1. Let $M \rightarrow \mathbb{R}^3$ be a surface, and $X \in M_p$ a unit vector. Let Σ be the circle in the plane perpendicular to X which is tangent to M at p and has radius $1/|\kappa(X)|$. Show that for every curve c in M with $c'(0) = X$, the center of the

osculating circle of c at 0 lies on Σ . The picture below is a hint.

2. Let $c: \mathbb{R} \rightarrow \mathbb{R}^3$ be a curve which lies on a sphere of radius r .
- (a) We have $\kappa_n = 1/r$, and consequently $\kappa = \sqrt{1/r^2 + \kappa_g^2} > 0$.
- (b) If $\mathbf{t}, \mathbf{n}, \mathbf{b}$ is the Frenet frame of c , and $\mathbf{v}(s) = \nu(c(s))$, where ν is the unit normal of the sphere in which c lies, then

$$\begin{aligned} 0 &= \langle \mathbf{t}, \mathbf{v} \rangle' = \kappa \langle \mathbf{n}, \mathbf{v} \rangle + 1/r \\ \langle \mathbf{n}, \mathbf{v} \rangle' &= \tau \langle \mathbf{b}, \mathbf{v} \rangle \\ \langle \mathbf{b}, \mathbf{v} \rangle' &= -\tau \langle \mathbf{n}, \mathbf{v} \rangle. \end{aligned}$$

- (c) If $\kappa' = 0$, then $\tau = 0$. If κ' is nowhere 0, then τ is nowhere 0 and

$$\frac{\tau}{\kappa} + \left[\frac{1}{\tau} \left(\frac{1}{\kappa} \right)' \right]' = 0.$$

- (d) Conversely, if this condition holds, then c lies on some sphere.
 (e) For convenience, say $r = 1$, so that

$$\kappa = \sqrt{1 + \kappa_g^2}.$$

Let $\mathbf{t}, \mathbf{u}, \mathbf{v}$ be the Darboux frame for c . By differentiating the equations

$$\begin{aligned}\mathbf{t}' &= \kappa_g \mathbf{u} + \mathbf{v} \\ \mathbf{t}' &= \kappa \mathbf{n},\end{aligned}$$

show that

$$\tau = \frac{\kappa_g'}{1 + \kappa_g^2}.$$

3. (a) Let $X \in M_p$ be a unit vector, and suppose that the geodesic γ with $\gamma'(0) = X$ has $\kappa(0) = 0$. Then

$$|\tau_g(X)| = \sqrt{-K(p)}.$$

- (b) If γ is a geodesic with $\gamma'(0) \in M_p$ a principal vector and $\kappa(0) = 0$, then $K(p) = 0$.
 (c) If γ_i are geodesics with perpendicular tangent vectors $\gamma_i'(0) \in M_p$, and $\kappa_1(0) = 0$, but $\kappa_2(0) \neq 0$, then the torsion $\tau_2(0)$ of γ_2 satisfies

$$|\tau_2(0)| = \sqrt{-K(p)}.$$

4. (a) Let c be an arclength parameterized curve on a surface $M \subset \mathbb{R}^3$ such that $c'(0) \in M_p$ is an asymptotic direction. If c is *not* asymptotic at p [$c''(0) \notin M_p$], then $\kappa(0) = 0$.

- (b) Now suppose that $c''(0) \in M_p$. Let \bar{c} be the arclength parameterized asymptotic curve with $\bar{c}'(0) = c'(0)$, and denote the curvature and torsion of \bar{c} by $\bar{\kappa}$ and $\bar{\tau}$.

Using Laguerre's formulation of Proposition 4, and equation (13) on page 192, show that

$$\begin{aligned}\kappa(0)[3\bar{\tau}(0) - \tau(0)] &= 2\bar{\tau}(0)\bar{\kappa}(0) \\ \implies \kappa(0)[\pm 3\sqrt{-K(p)} - \tau(0)] &= \pm 2\sqrt{-K(p)}\bar{\kappa}(0).\end{aligned}$$

(c) Show that at a point $p \in M$ where $K(p) < 0$, the intersection of M and the tangent plane at p consists of two curves which cross each other at p , and which point in the asymptotic directions. For either of these curves, show that

the curvature at p is $2/3$ times the curvature of the corresponding asymptotic curve through p (Beltrami).

5. Let $M \subset \mathbb{R}^3$ be a surface, and let X_1, X_2 be an orthonormal moving frame, in terms of which we write

$$\Pi = \sum_{i,j} l_{ij} \theta^i \otimes \theta^j.$$

(a) By Problem 2-5 we have

$$\nabla \Pi = \sum_{i,j,k} l_{ij;k} \theta^i \otimes \theta^j \otimes \theta^k$$

where

$$\sum_k l_{ij;k} \theta^k = dl_{ij} - \sum_\rho l_{\rho j} \omega_i^\rho - \sum_\rho l_{i\rho} \omega_j^\rho.$$

If X_1, X_2 is the frame X, \bar{X} in the proof of Proposition 4, apply this equation to X_1 to obtain

$$(1) \quad l_{11;1} = \frac{dl_{11}}{ds} - 2l_{12} \cdot \omega_1^2(X_1),$$

and deduce the first part of Proposition 4. Deduce the second part similarly.

(b) Show that

$$d\psi_i^3 = \sum_j dl_{ij} \wedge \theta^j - \sum_{j,\rho} l_{ij} \omega_\rho^j \wedge \theta^\rho.$$

Conclude from equation (1) that

$$(l_{12;1} - l_{11;2})\theta^1 \wedge \theta^2 = 0.$$

(c) If

$$\nabla \nabla \Pi = \sum_{i,j,k,h} l_{ij;kh} \theta^i \otimes \theta^j \otimes \theta^k \otimes \theta^h,$$

show that

$$\begin{aligned} l_{11;11} &= \frac{dl_{11;1}}{ds} - 3l_{12;1}\omega_1^2(X_1) \\ l_{12;11} &= \frac{dl_{12;1}}{ds} - (2l_{22;1} - l_{11;1})\omega_1^2(X_1) \\ &= \frac{dl_{12;1}}{ds} - \left(2\left[2\frac{dH}{ds} - l_{11;1}\right] - l_{11;1}\right)\omega_1^2(X_1). \end{aligned}$$

(d) For all arclength parameterized curves c in M with the same tangent vector $c'(0) \in M_p$ the quantity

$$\kappa_n''(s) - 2\tau_g(s)\kappa_g'(s) - 5\tau_g'(s)\kappa_g(s) - 6[\kappa_n(s) - H(c(s))]\kappa_g^2(s)$$

has the same value at $s = 0$. The same is true for

$$\begin{aligned} \tau_n''(s) + [2\kappa_n(s) - H(c(s))]\kappa_g'(s) \\ + \left[5\kappa_n'(s) - 6\tau_g(s)\kappa_g(s) - 6\frac{dH(c(s))}{ds}\right]\kappa_g(s). \end{aligned}$$

6. Let $X \in M_p$ be a principal vector, and c the principal curve with $c'(0) = X$.

- (a) Determine $\kappa_n'(0)$.
- (b) Use Problem 5 to determine $\kappa_g'(0)$ [in terms of $X(H)$].
- (c) Show how to determine $\kappa'(0)$.
- (d) Show how to use equation (7) on page 189 to determine $\phi'(0)$, and then how to find $\tau(0)$.

7. Let $\pi: \tilde{M} \rightarrow M$ be an n -fold covering of a compact orientable manifold M .

- (a) Let X be a vector field on M with only finitely many zeros. Show that there is a vector field \tilde{X} on \tilde{M} with n zeros of index ι for every zero of X with index ι . Conclude that $\chi(\tilde{M}) = n \cdot \chi(M)$.
- (b) Also prove this result by finding a triangulation of M for which there is a corresponding triangulation of \tilde{M} with n k -simplexes for each k -simplex of M .

8. Equation (*) on page 205 is the basis for the best coordinate system for ellipsoids and hyperboloids of one or two sheets. For given (x, y, z) let $\phi(\lambda)$ be the cubic

$$(1) \quad \phi(\lambda) = (a^2 - \lambda)(b^2 - \lambda)(c^2 - \lambda)(g(\lambda) - 1),$$

with roots

$$\lambda_1 < a^2, \quad a^2 < \lambda_2 < b^2, \quad b^2 < \lambda_3 < c^2.$$

Clearly

$$\phi(\lambda) = (\lambda_1 - \lambda)(\lambda_2 - \lambda)(\lambda_3 - \lambda).$$

(a) Substituting for the expression for $\phi(\lambda)$ from (1), and choosing $\lambda = a^2, b^2$, and c^2 , obtain

$$x^2 = \frac{(a^2 - \lambda_1)(a^2 - \lambda_2)(a^2 - \lambda_3)}{(a^2 - b^2)(a^2 - c^2)}$$

$$y^2 = \frac{(b^2 - \lambda_1)(b^2 - \lambda_2)(b^2 - \lambda_3)}{(b^2 - a^2)(b^2 - c^2)}$$

$$z^2 = \frac{(c^2 - \lambda_1)(c^2 - \lambda_2)(c^2 - \lambda_3)}{(c^2 - a^2)(c^2 - b^2)}.$$

(b) Setting one $\lambda_i = \text{constant}$, these equations give a parameterization of the surface $g(\lambda_i) = 1$ by means of the two other variables λ_j, λ_k . Setting

$$\begin{aligned} a^2 - \lambda_i &= \alpha, & b^2 - \lambda_i &= \beta, & c^2 - \lambda_i &= \gamma \\ \lambda_j - \lambda_i &= u, & \lambda_k - \lambda_i &= v, \end{aligned}$$

we have the surface

$$\frac{x^2}{\alpha} + \frac{y^2}{\beta} + \frac{z^2}{\gamma} = 1$$

parameterized by

$$x = \sqrt{\frac{\alpha(\alpha - u)(\alpha - v)}{(\alpha - \beta)(\alpha - \gamma)}}$$

$$y = \sqrt{\frac{\beta(\beta - u)(\beta - v)}{(\beta - \alpha)(\beta - \gamma)}}$$

$$z = \sqrt{\frac{\gamma(\gamma - u)(\gamma - v)}{(\gamma - \alpha)(\gamma - \beta)}}.$$

Note that the u - and v -parameter lines are clearly lines of curvature. Calculate that

$$E = \frac{u(u-v)}{f(u)} \quad F = 0 \quad G = \frac{v(v-u)}{f(v)}$$

where $f(t) = 4(\alpha - t)(\beta - t)(\gamma - t)$.

9. Let $f: \mathbb{C} \rightarrow \mathbb{C}$ be

$$f(x, y) = f(x + iy) = (u(x, y), v(x, y)) = u(x, y) + iv(x, y)..$$

(a) Calculate that

$$\begin{aligned} f^*(dx \otimes dx + dy \otimes dy) &= (u_x^2 + v_x^2) dx \otimes dx + (u_y^2 + v_y^2) dy \otimes dy \\ &\quad + (u_x u_y + v_x v_y)(dx \otimes dy + dy \otimes dx). \end{aligned}$$

Conclude that f is conformal if and only if

$$u_x^2 + v_x^2 = u_y^2 + v_y^2 \quad \text{and} \quad u_x u_y + v_x v_y = 0.$$

(b) Show that f is conformal if and only if

$$u_x = \pm v_y, \quad u_y = \mp v_x.$$

Hint: Multiply the first equation of part (a) by v_y^2 .

10. Consider the map

$$I(x) = \frac{x}{|x|^2} \quad x \in \mathbb{R}^3 - \{0\}.$$

(a) If $S^2(r)$ is the 2-sphere around 0 of radius r , and $X \in S^2(r)_p$, then $I_*(X) \in S^2(\frac{1}{r})_{I(p)}$ is parallel to X , and $|I_*(X)| = \frac{1}{r}|X|$.

(b) If v is the unit normal to $S^2(r)$ at p , then $I_*(v)$ is $\frac{1}{r}$ times the unit normal to $S^2(\frac{1}{r})$ at $I(p)$.

(c) I is conformal.

11. Note that Lemma 13 is valid also for $U, V \subset \mathbb{R}^2$, where $f: U \rightarrow V$ takes portions of straight lines and circles to portions of straight lines and circles. Conclude that if f is orientation preserving, then f is of the form

$$f(z) = \frac{az + b}{cz + d}, \quad a, b, c, d \in \mathbb{C}.$$

12. Use Clairaut's Theorem to analyze the geodesics on a torus. (The fact that points with different values of r can have the same height is confusing, but irrelevant; it may help to think of the torus in terms of the profile curve on the right, but with the end points identified.)

Answer: All geodesics, except the inner parallel, intersect the outer parallel. Those which intersect at a small angle θ describe a sine-like curve between two parallels at equal distances from the outer one. For a certain angle θ we obtain a sine-like curve between the top and bottom parallels. For somewhat larger θ the curve flops over the top and bottom and bounces between two parallels on the inner part of the torus. For a certain angle θ we obtain a curve which approaches the inner parallel asymptotically. For slightly larger θ the geodesic hits the inner parallel, at a small angle, after going around many times. As θ increases, the geodesic hits the inner parallel at larger angles, after going around fewer times, until, at $\theta = \pi/2$, we obtain a meridian circle.

13. From pg. II.131 we have the formula

$$W^4 K = \det \begin{pmatrix} -\frac{1}{2}G_{11} + F_{12} - \frac{1}{2}E_{22} & \frac{1}{2}E_1 & F_1 - \frac{1}{2}E_2 \\ F_2 - \frac{1}{2}G_1 & E & F \\ \frac{1}{2}G_2 & F & G \end{pmatrix} \\ - \det \begin{pmatrix} 0 & \frac{1}{2}E_2 & \frac{1}{2}G_1 \\ \frac{1}{2}E_2 & E & F \\ \frac{1}{2}G_1 & F & G \end{pmatrix},$$

where $W = \sqrt{EG - F^2}$. Verify the following (seemingly non-rational) expression for K , due to Frobenius:

$$K = -\frac{1}{4W^4} \det \begin{pmatrix} E & E_1 & E_2 \\ F & F_1 & F_2 \\ G & G_1 & G_2 \end{pmatrix} + \frac{1}{2W} \left[\left(\frac{F_2 - G_1}{W} \right)_1 + \left(\frac{F_1 - E_2}{W} \right)_2 \right]$$

14. Let $f: U \rightarrow M$ be an imbedding whose parameter curves are asymptotic curves, so that

$$f_{11} = Af_1 + Bf_2, \quad f_{22} = Cf_1 + Df_2.$$

Choose the orientation so that $\det(f_1, f_2, f_{12}) > 0$.

(a) For the affine first fundamental form \mathfrak{I}_f we have

$$g_{11} = g_{22} = 0 \quad \text{and} \quad g_{12} = \sqrt{\det(f_1, f_2, f_{12})} = \alpha, \text{ say.}$$

(b) The Christoffel symbols for \mathfrak{I}_f are

$$[11, 2] = \alpha_1, \quad [22, 1] = \alpha_2, \quad \text{all other } [ij, k] = 0.$$

$$\Gamma_{11}^1 = \frac{\alpha_1}{\alpha}, \quad \Gamma_{22}^2 = \frac{\alpha_2}{\alpha}, \quad \text{all other } \Gamma_{ij}^k = 0,$$

so

$$\nabla_{f_1} f_1 = \frac{\alpha_1}{\alpha} f_1, \quad \nabla_{f_2} f_2 = \frac{\alpha_2}{\alpha} f_2.$$

(c) We have

$$\mathfrak{A}(f_i, f_j) = f_{ij} - \nabla_{f_i} f_j \implies \ell_{ijk} = \langle f_{ij} - \nabla_{f_i} f_j, f_k \rangle,$$

and consequently

$$\ell_{111} = B\alpha, \quad \ell_{112} = A\alpha - \alpha_1, \quad \ell_{221} = D\alpha - \alpha_2, \quad \ell_{222} = C\alpha.$$

(d) Show that

$$\begin{aligned} (\ell_{111})^2 &= \det(f_1, f_{11}, f_{111}) \\ -(\ell_{222})^2 &= \det(f_2, f_{22}, f_{222}). \end{aligned}$$

[This gives another proof to the second part of Theorem 7.]

(e) Show that

$$\ell_{112} = \ell_{221} = 0.$$

Thus

$$\mathfrak{I}_f = \sqrt{\det(f_1, f_{11}, f_{111})} ds^1 \otimes ds^1 \otimes ds^1 + \sqrt{-\det(f_2, f_{22}, f_{222})} ds^2 \otimes ds^2 \otimes ds^2.$$

15. (a) For the parameterization in Problem 14, show that the Pick invariant is

$$J = \frac{\ell_{111}\ell_{222}}{(g_{12})^3}.$$

(b) On a region of M where $\ell_{111} = 0$, we have $f_{11} = af_1$. Hence M is a ruled surface. Similarly on a region where $\ell_{222} = 0$. Conversely, a ruled surface has $J = 0$.

16. As an alternative to the approach taken in Problem 3-11, use Problem 14 to show that a doubly ruled surface with $K < 0$ has $\mathfrak{T} = 0$, so that it is quadratic, by Proposition 2-19.
17. Show that a compact Riemannian 2-manifold can be triangulated by choosing the vertices to be an ε -dense set, where every point has a geodesically convex neighborhood of radius $> \varepsilon$, and choosing the edges to be geodesic segments.

CHAPTER 5

COMPLETE SURFACES OF CONSTANT CURVATURE

We have already seen, in Chapter 3, that there are many surfaces with constant curvature. On the other hand, few of our examples were complete manifolds. In this chapter we will determine precisely which surfaces in \mathbb{R}^3 can be obtained by isometrically immersing complete manifolds with constant curvature $K > 0$, $K = 0$, or $K < 0$.

In the case of complete surfaces of constant curvature $K > 0$ we will actually assume that the surface is compact; in Chapter 8 (Theorem 8-17), however, we will see that this additional hypothesis is superfluous. By Hadamard's Theorem, our surface is an imbedded submanifold $M \subset \mathbb{R}^3$.

1. LEMMA (HILBERT). Let M be a surface immersed in \mathbb{R}^3 , and let $p \in M$ be a non-umbilic point. Let $k_1 \geq k_2$ be the two principal curvatures on M and suppose that k_1 has a local maximum at p , and k_2 has a local minimum at p . Then $K(p) \leq 0$.

PROOF. According to Addendum 1 to Chapter 4, we can choose an imbedding $f: U \rightarrow M$, with $p \in f(U)$, whose coordinate lines are the lines of curvature. Then Gauss' equation and the Codazzi-Mainardi equations become [subscripts, except those on k_1 and k_2 , denote partial derivatives]

$$(1) \quad K = -\frac{1}{2\sqrt{EG}} \left[\left(\frac{E_2}{\sqrt{EG}} \right)_2 + \left(\frac{G_1}{\sqrt{EG}} \right)_1 \right]$$

$$(2) \quad l_2 = \frac{E_2}{2} \left(\frac{l}{E} + \frac{n}{G} \right) = \frac{E_2}{2} (k_1 + k_2)$$

$$(3) \quad n_1 = \frac{G_1}{2} \left(\frac{l}{E} + \frac{n}{G} \right) = \frac{G_1}{2} (k_1 + k_2);$$

the second equalities in (2) and (3) follow from the fact that

$$l = k_1 E, \quad n = k_2 G.$$

Moreover, differentiation of these last two equations yields

$$l_2 = \frac{\partial k_1}{\partial t} E + k_1 E_2, \quad n_1 = \frac{\partial k_2}{\partial s} G + k_2 G_1.$$

(The functions k_i are differentiable near p , since the functions H and K are differentiable, and $k_i = H \pm \sqrt{H^2 - K}$, where $H^2 - K > 0$ in a neighborhood of the non-umbilic point p .) Together with (2) and (3) we then have

$$(2') \quad E_2 = -\frac{2E}{k_1 - k_2} \cdot \frac{\partial k_1}{\partial t}$$

$$(3') \quad G_1 = \frac{2G}{k_1 - k_2} \cdot \frac{\partial k_2}{\partial s}.$$

Substituting (2'), (3') into (1) gives

$$(1') \quad K = -\frac{1}{2EG} \left[-\frac{2E}{k_1 - k_2} \cdot \frac{\partial^2 k_1}{\partial t^2} + \frac{2G}{k_1 - k_2} \cdot \frac{\partial^2 k_2}{\partial s^2} \right] \\ + (\text{something continuous}) \cdot \frac{\partial k_1}{\partial t} \\ + (\text{something continuous}) \cdot \frac{\partial k_2}{\partial s}.$$

Since k_1 has a local maximum at p , and k_2 a local minimum, we have

$$\frac{\partial k_1}{\partial t}(p) = \frac{\partial k_2}{\partial s}(p) = 0, \quad \frac{\partial^2 k_1}{\partial t^2}(p) \leq 0, \quad \frac{\partial^2 k_2}{\partial s^2}(p) \geq 0.$$

Together with (1') this shows that $K(p) \leq 0$. ♦

2. THEOREM. If M is a compact connected surface in \mathbb{R}^3 with constant curvature $K > 0$, then M is a sphere.

PROOF. Let $k_1 \geq k_2$ be the principal curvatures on M , and let p be a point where k_1 achieves its maximum. Then $k_2 = K/k_1$ has its minimum at p . If we had $k_1(p) > k_2(p)$, so that p was not an umbilic, then the Lemma would imply that $K(p) \leq 0$, a contradiction. Hence $k_1(p) = k_2(p)$. Moreover, for any point $q \in M$ we then have

$$k_1(p) \geq k_1(q) \geq k_2(q) \geq k_2(p) = k_1(p),$$

so also $k_1(q) = k_2(q)$. Thus all points of M are umbilics, and Theorem 2-2 applies. ♦

We also have another result of interest:

3. **THEOREM.** If M is a compact connected surface in \mathbb{R}^3 , with K everywhere > 0 , and constant mean curvature H , then M is a sphere.

PROOF. As before, if k_1 achieves its maximum at p , then $k_2 = H - k_1$ achieves its minimum. Since we are assuming $K(p) > 0$, we find that $k_1(p) = k_2(p)$, and the rest of the proof proceeds as before. ♦

We now turn our attention to immersed surfaces M in \mathbb{R}^3 which are flat, that is, which have $K = 0$ everywhere. We know that if a connected open set $U \subset M$ consists entirely of planar points, then U is part of a plane. Let us consider a point of M which is *not* a planar point, and hence a parabolic point. In a neighborhood U of this point we can choose a C^∞ unit vector field X_1 such that each $X_1(q)$ is a principal vector with principal curvature $k_1(q) = 0$, and another C^∞ unit vector field X_2 , orthogonal to X_1 , such that each $X_2(q)$ is a principal vector with principal curvature $k_2(q) \neq 0$.

4. **PROPOSITION.** The integral curves of X_1 are straight line segments. Consequently, every non-planar point in a flat surface has a neighborhood which is a ruled surface.

PROOF. Let $\theta^i, \omega_1^2, \psi_i^3$ be the forms associated with the adapted orthonormal moving frame (X_1, X_2, ν) . Since

$$\nabla'_{X_i} \nu = \begin{cases} 0 & i = 1 \\ k_2 X_2 & i = 2, \end{cases}$$

we have

$$\begin{aligned} \psi_1^3(X_i) &= -\psi_3^1(X_i) = -\langle X_1, \nabla'_{X_i} \nu \rangle = 0 \\ \psi_2^3(X_i) &= -\psi_3^2(X_i) = -\langle X_2, \nabla'_{X_i} \nu \rangle = -k_2 \theta^2(X_i). \end{aligned}$$

In short, we have

$$\psi_1^3 = 0, \quad \psi_2^3 = -k_2 \theta^2,$$

so one of the Codazzi-Mainardi equations (page 70) gives

$$0 = d\psi_1^3 = -\psi_2^3 \wedge \omega_1^2 = k_2 \theta^2 \wedge \omega_1^2.$$

Since k_2 is never 0, this can happen only if ω_1^2 is always a multiple of θ^2 . This implies that

$$0 = \omega_1^2(X_1) = \langle \nabla'_{X_1} X_1, X_2 \rangle,$$

while we also have

$$0 = \psi_1^3(X_1) = \langle \nabla'_{X_1} X_1, X_3 \rangle.$$

Therefore $\nabla'_{X_1} X_1 = 0$, which means that the integral curves of X_1 are straight lines in \mathbb{R}^3 . ♦

We still haven't said what happens at a planar point which is a limit of parabolic points, but before worrying about such points, we will first obtain some information about flat ruled surfaces, classically known as **developable surfaces**.

Consider a ruled surface

$$(1) \quad f(s, t) = c(s) + t\delta(s),$$

where we assume $|\delta| = 1$ for convenience, but do not necessarily insist on the canonical parameterization (since it is not always possible to introduce it). As we have seen (page 147 and page 197), this surface is flat precisely when c', δ, δ' are everywhere linearly dependent. Let us first consider an open interval for s on which δ, δ' alone are *everywhere linearly dependent*. Since $|\delta| = 1$, we have $\langle \delta, \delta' \rangle = 0$, so actually δ' must be 0, and δ is constant. We then have a portion of a cylinder. Next let us consider an interval on which δ, δ' are *everywhere linearly independent*. Then there are unique C^∞ functions α, β with

$$(2) \quad c'(s) = \alpha(s)\delta(s) + \beta(s)\delta'(s).$$

Let

$$(3) \quad c^*(s) = c(s) - \beta(s)\delta(s).$$

Then

$$(4) \quad \begin{aligned} c^{*'}(s) &= c'(s) - \beta(s)\delta'(s) - \beta'(s)\delta(s) \\ &= [\alpha(s) - \beta'(s)]\delta(s). \end{aligned}$$

Again, we will consider only two special cases. On an interval where $\alpha(s) - \beta'(s)$ is *always* 0, we have $c^*(s) = \text{constant vector } c_0^*$, and by (1) and (3) our surface is

$$f(s, t) = c_0^* + (t + \beta(s))\delta(s),$$

which is a portion of the cone

$$g(s, t) = c_0^* + t\delta(s).$$

On the other hand, on an interval where $\alpha(s) - \beta'(s)$ is *never* 0, we have

$$(5) \quad \delta(s) = \frac{c^{*'}(s)}{\alpha(s) - \beta'(s)},$$

so by (1) and (3) our surface is

$$\begin{aligned} f(s, t) &= c(s) + t\delta(s) = c^*(s) + (t + \beta(s))\delta(s) \\ &= c^*(s) + \left[\frac{t + \beta(s)}{\alpha(s) - \beta'(s)} \right] c^{*'}(s), \end{aligned}$$

which is a portion of the tangent developable

$$g(s, t) = c^*(s) + tc^{*'}(s)$$

of the curve c^* . [Notice that by (4) we have

$$c^{*''}(s) = (\alpha(s) - \beta'(s))\delta'(s) + (\alpha'(s) - \beta''(s))\delta(s);$$

since we are on an interval where δ' and δ are linearly independent and $\alpha - \beta'$ is nowhere 0, this shows that the curve c^* does indeed have non-vanishing curvature on the interval.]

The discussion in the preceding paragraph constitutes the classical “classification” of developable surfaces, which was commonly expressed by saying that all developables are planes, cylinders, cones, or tangent developables. We have clearly not proved any such result, since we have only considered special intervals on which certain conditions hold. Nowadays people tend to say: Oh well, the classical classification of developables was really for analytic surfaces—one ought to say that a connected *analytic* developable surface is either a plane, cylinder, cone, or tangent developable. But *even this* is not true. It is true that if a connected analytic developable surface contains a plane, cylinder or cone, then it must be a plane, cylinder, or cone; for planes, cylinders, and cones are the surfaces which arise in our analysis when certain functions are zero on a whole interval. But an analytic developable surface can also be made up of several tangent developables joined together along a line belonging to neither. For example, consider the analytic function $\delta: \mathbb{R} \rightarrow S^2$ defined by

$$(1) \quad \delta(s) = \frac{1}{\sqrt{(1+s^2)^2 + (1+s^3)^2 + s^8}} \cdot (1+s^2, 1+s^3, s^4).$$

We clearly have

$$(2) \quad \delta'(s) = sA(s)$$

for some analytic function A , and we easily check that

$$(3) \quad A(0) \text{ is not a multiple of } \delta(0).$$

Now let $c: \mathbb{R} \rightarrow \mathbb{R}^3$ be an analytic curve with $c(0) = 0$ and

$$(4) \quad c'(s) = \delta(s) + A(s).$$

Since $c'(0) = \delta(0) + A(0)$ is linearly independent of $\delta(0)$ [by (3)], the map

$$f(s, t) = c(s) + t\delta(s)$$

is an immersion at $(0, t)$ for all t . We claim that f is flat at all points, i.e., that $c'(s), \delta(s), \delta'(s)$ are linearly dependent for all s . This is clear for $s = 0$, since $\delta'(0) = 0$, while for $s \neq 0$ we have, by (4),

$$c'(s) = 1 \cdot \delta(s) + \frac{1}{s}\delta'(s).$$

This equation, together with equation (3) on page 236, shows that for $s \neq 0$ our surface is the tangent developable of the curve

$$c^*(s) = c(s) - \frac{1}{s}\delta(s).$$

Since c and δ are analytic, c^* is definitely *not* analytic at 0. Instead we have two different curves for $s > 0$ and $s < 0$; it is easy to see that

$$c^*(s) \rightarrow (-\infty, -\infty, 0) \quad \text{as } s \rightarrow 0^+$$

$$c^*(s) \rightarrow (\infty, \infty, 0) \quad \text{as } s \rightarrow 0^-.$$

Our surface looks something like the following picture:

The possible complexity of analytic developables is perhaps most strikingly illustrated by the fact that there is an *analytic* developable surface which is homeomorphic to the Möbius strip; it may be constructed as follows (see Wunderlich [1] for details). We take an analytic closed curve c which looks like the center line of the paper Möbius strip. In the paper model, this line is a geodesic,

desic, since it comes from a straight line in the flat piece of paper which we bent to form the Möbius strip. So we want a developable surface on which c is a geodesic. This can be obtained by taking the rectifying developable of c (Problem 3-13); because of the way c twists, its rectifying developable twists so as to be homeomorphic to the Möbius strip.

Since so many complexities arise even for analytic developables, it might seem hopeless to say anything at all about flat surfaces which are merely C^∞ , and which may contain planar points (in which case we cannot even be sure that they are ruled surfaces). To see how C^∞ flat surfaces can be different from analytic ones, consider the two surfaces pictured below. The first is obtained by

rolling up three pieces of a disc (choosing an appropriate profile for the rolled up portions, so that the surface is C^∞), the second by gluing a cylinder and a cone to a plane. In Chapter 3, our construction of a C^∞ flat Möbius strip gave another example, in which two tangent developables were glued together in a C^∞ , but non-analytic, way. In the above pictures we have singled out certain points p which are planar points, but at the same time the limit of parabolic points. In each case there are segments (indicated by dashed lines) which have p as an endpoint, but which cannot be extended past p in the other direction.

On the other hand, these rays do not go through parabolic points; in fact, most of the points on them lie in completely planar regions. Moreover, in each case there is also a segment (indicated by heavy lines) containing p in its interior. We will show that this situation is completely typical. The main tool is a Lemma which is obtained by following the philosophically prescribed route:

5. LEMMA. Let p be a parabolic point on a flat surface M immersed in \mathbb{R}^3 , let $L_p \subset \mathbb{R}^3$ be the straight line containing the integral curve through p of the vector field of Proposition 4, and let O_p be the component containing p of the set of points in $L_p \cap M$ where $k_2 \neq 0$. Let c be the arclength parameterization of L_p , with $c(0) = p$, and let $k(s) = k_2(c(s))$. Then on O_p the function k is of the form

$$k(s) = \frac{1}{As + B}$$

for some constants A and B .

PROOF. We keep the same notation as in the proof of Proposition 4, so that we have

$$(1) \quad \psi_1^3 = 0, \quad (2) \quad \psi_2^3 = -k_2\theta^2.$$

We have already found, using one of the Codazzi-Mainardi equations, that ω_1^2 is always a multiple of θ^2 . This means that on the region where $k_2 \neq 0$ it is also a multiple of ψ_2^3 , say

$$(3) \quad \omega_1^2 = g\psi_2^3.$$

Now we use the *other* Codazzi-Mainardi equation, to obtain

$$(4) \quad d\psi_2^3 = -\psi_1^3 \wedge \omega_2^1 = 0 \quad \text{by (1).}$$

Thus

$$\begin{aligned} 0 = d\psi_2^3 &= -dk_2 \wedge \theta^2 - k_2 d\theta^2 && \text{by (2)} \\ &= -dk_2 \wedge \theta^2 + k_2 \omega_1^2 \wedge \theta^1, \end{aligned}$$

and therefore

$$dk_2 \wedge \theta^2 = -k_2 \theta^1 \wedge \omega_1^2.$$

Applying this to (X_1, X_2) gives

$$\begin{aligned} (*) \quad X_1(k_2) &= -k_2 \omega_1^2(X_2) \\ &= -k_2 g \psi_2^3(X_2) && \text{by (3)} \\ &= (k_2)^2 g && \text{by (2).} \end{aligned}$$

We also want to use the Gauss equation $d\omega_1^2 = -K\theta^1 \wedge \theta^2$ (page 69). Since $K = 0$, this says that

$$(5) \quad d\omega_1^2 = 0.$$

Hence

$$\begin{aligned} 0 = d\omega_1^2 &= d(g\psi_2^3) && \text{by (3)} \\ &= dg \wedge \psi_2^3 + 0 && \text{by (4)} \\ &= -k_2 dg \wedge \theta^2 && \text{by (2).} \end{aligned}$$

Applying this to (X_1, X_2) gives $dg(X_1) = 0$. In other words,

$$(**) \quad g \text{ is constant along the integral curves of } X_1.$$

From (*) and (**) we see that the function $k(s) = k_2(c(s))$ satisfies the differential equation

$$(***) \quad k'(s) = -Ak(s)^2 \quad \text{for some constant } A.$$

We can solve this explicitly: Since

$$-\frac{k'}{k^2} = \left(\frac{1}{k}\right)',$$

we have

$$k(s) = \frac{1}{As + B}.$$

More precisely, by suitable choice of B we obtain any desired initial condition $k(0)$ except $k(0) = 0$ —the solution with this initial condition is simply $k = 0$. But $k(0) \neq 0$ by assumption, so our k has the above form. ♦

6. COROLLARY. Let p be a parabolic point on a flat surface M immersed in \mathbb{R}^3 . Then there is a unique straight line L_p through p such that the component C_p of $M \cap L_p$ which contains p is an interval (possibly infinite) with p in its interior. All the points of C_p are also parabolic. Moreover, C_p cannot end in M ; that is, if C_p has an endpoint q , then q is not in M .

PROOF. Existence of L_p follows from Proposition 4, and uniqueness is obvious,* since there cannot be two distinct asymptotic directions at p . If there were non-parabolic points of C_p , then one of them would be an endpoint of the interval O_p of Lemma 5. If this point is $q = c(s_0)$, then we would have

$$0 = k_2(q) = k_2(c(s_0)) = \lim_{s \rightarrow s_0} \frac{1}{As + B},$$

which is impossible. Thus all points of C_p are parabolic, and $C_p = O_p$. Similarly, if C_p had an endpoint $q \in M$, then $k_2(q)$ could not be 0, so q would also be a parabolic point, and a neighborhood of q would be a ruled surface. From this it is clear that C_p could be extended to include q in its interior, which gives a contradiction. ♦

Once we have this Corollary, the next two follow by completely elementary argumentation.

7. COROLLARY. Let M be a flat surface immersed in \mathbb{R}^3 , and let $p \in M$ be a planar point which is a limit of parabolic points p_n . Then the conclusion of Corollary 6 still holds, except that all points of C_p are now planar points which are limits of parabolic points.

PROOF. Some subsequence of the straight lines L_{p_n} have a limiting direction. Let L_p be the straight line through p with this limiting direction. The components C_{p_n} have p_n in their interior; moreover, Corollary 6 shows that the lengths of the C_{p_n} are bounded away from 0 in each direction from p_n . It follows that C_p has p in its interior. The assertion about endpoints of C_p is an immediate consequence of the same property for the C_{p_n} . It is also clear that all points of C_p are limits of parabolic points, since all points of each C_{p_n} are parabolic. If some point of C_p itself were a parabolic point, then, by Corollary 6, all points of C_p would be parabolic points, including p itself, a contradiction. To prove uniqueness, notice that another straight line L' through p would have to intersect C_{p_n} for large enough n ; thus L' would contain parabolic points, so all points on L' would be parabolic points, including p itself, a contradiction. ♦

*A “counterexample” is shown in the figure on the right: since we are dealing with immersed surfaces, the uniqueness has to be given a careful formulation, which is left to the reader. We will also be somewhat sloppy about such questions in the sequel, since the precise statements are always clear, but irritatingly messy to state.

8. COROLLARY. Every point p of a flat surface M immersed in \mathbb{R}^3 is contained in the interior of some line segment lying in M . This segment is unique unless some neighborhood of p is a plane, and the only segments which can end in M are those whose interior points are of this type.

R. Malz likes to point out that this result has a very important application in everyday life. If one holds a piece of paper in the shape of a cylinder, then

it will stay stiff even if it is very long; however, as soon as it is allowed to be planar, it will flop down under gravity. That is why people always curl up a pile of papers when they try to align it by tapping it on a desk top.

At this point it is almost clear that a *complete* flat surface M immersed in \mathbb{R}^3 must be a generalized cylinder. For an open dense subset of M will be a union of pieces of planes, cylinders, cones and tangent developables, where we can arrange for the latter 3 types to contain only parabolic points. Because of completeness, Corollaries 6 and 7 show that the generators of these cylinders, cones, and tangent developables must be infinite straight lines. But in the case of cones and tangent developables this is simply impossible, for there would definitely be singularities at the vertex or edge of regression. So an open dense subset of M consists of cylinders (some possibly degenerating to planes). It seems fairly clear that these cylinders must all have parallel generators if they and a nowhere dense closed set are somehow going to make up a smooth surface M ; but proving this might become quite sticky. Fortunately, there is a direct proof of the global result which makes no use whatsoever of the classical local classification.

9. THEOREM. If M is a complete flat surface and $f: M \rightarrow \mathbb{R}^3$ is an isometric immersion, then $f(M) \subset \mathbb{R}^3$ is a generalized cylinder.

FIRST PROOF. We can assume that M is simply-connected (by applying the result to $f \circ \pi$ where $\pi: \tilde{M} \rightarrow M$ is the universal covering space). Then (Problem 1-5) M is isometric to \mathbb{R}^2 , with its usual Riemannian metric.

We claim first that if $f(M)$ is not simply a plane in \mathbb{R}^3 , then for every point $p \in M$ there is a *unique* infinite straight line L_p through p which is contained in $f(M)$. Corollaries 6 and 7, together with completeness, show that this is true if p is parabolic or a limit of parabolic points. Now consider a point $p \in f(M)$ which has a whole neighborhood contained in a plane P . Let $Q \subset P$ be the component of $f(M) \cap P$ containing p . If Q is not all of P , let q be a boundary point of Q in P such that all points of the segment \overline{pq} other than q itself lie in the interior of Q (relative to P). The point q must lie in $f(M)$, by completeness,

so q is a planar point which is a limit point of parabolic points. Therefore q is on a unique straight line L_q in $f(M)$. The line L_q must lie in P , since P is the tangent space of q , by continuity of the tangent spaces; moreover, all points of L_q are planar points which are limits of parabolic points.

We claim that all points between p and L_q lie in Q also. Otherwise, there is a point r between p and L_q such that all points of \overline{pr} are in P , but r is also a limit of parabolic points.

There is a corresponding line L_r , and it must be parallel to L_q , since points on L_q and L_r have only one straight line passing through them. Thus L_r intersects \overline{pq} at r' . Then r' is also a limit of parabolic points, which is absurd, since r' is in the interior of Q , a component of $M \cap P$.

The same arguments may be applied if there are any boundary points of Q on the other side of p . Consequently, either $Q = P$, or Q is the part of P bounded by L_q , or Q is the part of P bounded by two parallel lines $L_q, L_{q'}$. Leaving aside the case where $Q = P$ (which occurs only if $f(M) = P$), we see that there is a unique infinite straight line through p in M , namely the one parallel to L_q [and $L_{q'}$]. This proves our claim.

Since f is an isometry, each L_p is the image under f of a geodesic (or possibly many geodesics) in \mathbb{R}^2 ; these geodesics are just ordinary straight lines. In this family of straight lines, distinct lines are disjoint, so our family is the set of lines in \mathbb{R}^2 parallel to a fixed line; for convenience we assume that they are all parallel to the y -axis.

Now by completeness, the functions k of Lemma 5 are defined for all s . But this can happen only if $A = 0$. So we see that all k are constants. In other words,

$$k_2(x, y) = \kappa(x)$$

for some function κ . On the other hand, consider the map $f: \mathbb{R}^2 \rightarrow \mathbb{R}^3$ defined by

$$g(x, y) = (c_1(x), c_2(x), y),$$

where c is a curve in \mathbb{R}^2 with curvature function κ . We easily compute that the maps f and g both have second fundamental forms with components

$$l = \kappa, \quad m = 0, \quad n = 0.$$

So by the fundamental theorem of surface theory, f differs from the generalized cylinder g by a Euclidean motion.

SECOND PROOF. We replace the last argument, using the fundamental theorem of surface theory, with some very elementary geometry. Any two parallel lines L_1 and L_2 of our family have the property that the function

$$p \mapsto d(p, L_2)$$

is constant on L_1 , where $d(p, L_2)$ is the distance (in \mathbb{R}^2) from p to L_2 . Since f is an isometry, the function $q \mapsto \bar{d}(q, f(L_2))$ must be constant on $f(L_1)$, where \bar{d} denotes the distance in $f(M)$. Now if $f(L_1)$ and $f(L_2)$ were skew lines, or lines intersecting at just one point, then the function

$$q \mapsto \text{Euclidean distance from } q \text{ to } f(L_2)$$

would $\rightarrow \infty$ as $q \rightarrow \infty$ along L_1 . Since

$$\bar{d}(q, f(L_2)) \geq \text{Euclidean distance from } q \text{ to } f(L_2),$$

the same would be true for \bar{d} , so \bar{d} could not be constant. Thus $f(L_1)$ and $f(L_2)$ must be parallel (or equal). So $f(M)$ is a generalized cylinder.

THIRD PROOF. This time we reduce almost everything to elementary geometry. We merely note that either all points of our surface are planar points, or by Corollaries 6 and 7, and completeness, *some* straight line of \mathbb{R}^2 maps to a straight line in \mathbb{R}^3 ; for simplicity we assume that $(0, y) \mapsto (0, y, 0)$. Consider first a point $(x, 0)$ of \mathbb{R}^2 . Its distance from $(0, d)$ is $\sqrt{x^2 + d^2}$. Since this must be the distance from $f(x, 0)$ to $f(0, d)$ in $f(M)$, the point $f(x, 0)$ must lie in the Euclidean ball around $(0, d, 0)$ of radius $\sqrt{x^2 + d^2}$. Similarly, $f(x, 0)$ must

lie in the Euclidean ball around $(0, -d, 0)$ of radius $\sqrt{x^2 + d^2}$. The intersection of these two balls is a lens-shaped region of height $2(\sqrt{x^2 + d^2} - d)$. Since this $\rightarrow 0$ as $d \rightarrow \infty$, the point $f(x, 0)$ must lie in the plane $y = 0$.

Now the same argument shows that $f(x, y_0)$ must lie in the plane $y = y_0$.

But $f(x, y_0)$ must also lie in the Euclidean ball of radius y_0 around $f(x, 0)$. So $f(x, y_0)$ must be on the line through $f(x, 0)$ parallel to the y -axis. ♦

The remainder of this chapter is devoted to the proof of Hilbert's theorem that there are *no* complete surfaces of constant negative curvature K immersed in \mathbb{R}^3 . There is no loss of generality in considering only the case $K = -1$, since similarities of \mathbb{R}^3 multiply K by a (positive) constant. We will actually give two proofs of this result. The second is related to, but considerably simpler than, the original proof of Hilbert [1], while the first is an alternative to Hilbert's argument, due to Holmgren [1]. The proofs depend on several classical formulas for surfaces of constant negative curvature, so in each case a few preparatory results are in order.

10. LEMMA. Let M be a 2-dimensional immersed submanifold of \mathbb{R}^3 with constant curvature $K < 0$. Then for every point $p \in M$ there is a diffeomorphism

$$\begin{aligned} g : (-\varepsilon, \varepsilon) \times (-\varepsilon, \varepsilon) &\rightarrow M, \\ g(0, 0) &= p, \end{aligned}$$

whose parameter curves are asymptotic curves *parameterized by arclength*.

A CLASSICAL PROOF. In Addendum 1 to Chapter 4 we found that for every $p \in M$ there is a diffeomorphism $g : (-\varepsilon, \varepsilon) \times (-\varepsilon, \varepsilon) \rightarrow M$, with $g(0, 0) = p$, such that the parameter curves are asymptotic curves. By a suitable reparameterization we can clearly arrange that the two parameter curves through $p = g(0, 0)$ are parameterized by arclength. Thus we have

$$(1) \quad E(s, 0) = 1, \quad G(0, t) = 1.$$

We now claim that *all* parameter curves are parameterized by arclength. To prove this we note that the Codazzi-Mainardi equations on page 217 can be written

$$(2) \quad \begin{aligned} (m^2)_1 &= 2 \frac{\left[\frac{1}{2}(EG - F^2)_1 + FE_2 - EG_1\right]}{EG - F^2} m^2 \\ (m^2)_2 &= 2 \frac{\left[\frac{1}{2}(EG - F^2)_2 + FG_1 - GE_2\right]}{EG - F^2} m^2. \end{aligned}$$

But we also have

$$K = \frac{ln - m^2}{EG - F^2} = \frac{-m^2}{EG - F^2},$$

so that

$$m^2 = (-K)(EG - F^2), \quad \text{where } K \text{ is a constant.}$$

Substituting in the first equation of (2), we get

$$(-K)(EG - F^2)_1 = 2(-K) \left[\frac{1}{2}(EG - F^2)_1 + FE_2 - EG_1 \right],$$

which becomes simply

$$EG_1 - FE_2 = 0.$$

Similarly,

$$-FG_1 + GE_2 = 0.$$

Since $EG - F^2 \neq 0$, this set of linear equations is satisfied only if $E_2 = 0$ and $G_1 = 0$. Together with (1), this shows that $E = 1$ and $G = 1$ everywhere.

SECOND PROOF. The desired result obviously amounts to the following: If Y_1 and Y_2 are linearly independent unit asymptotic vector fields, then $[Y_1, Y_2] = 0$.

First consider an adopted orthonormal moving frame (X_1, X_2, X_3) for which X_1 and X_2 are principal directions, with corresponding principal curvatures k_1 and k_2 . Then the forms ψ_i^3 satisfy

$$\psi_i^3 = k_i \theta^i.$$

We also have the Codazzi-Mainardi equations

$$d\psi_1^3 = \omega_1^2 \wedge \psi_2^3, \quad d\psi_2^3 = -\omega_1^2 \wedge \psi_1^3.$$

Taking the exterior derivative of the equation $\psi_1^3 = k_1 \theta^1$ thus yields

$$dk_1 \wedge \theta^1 + k_1 d\theta^1 = d\psi_1^3 = \omega_1^2 \wedge \psi_2^3 = k_2 \omega_1^2 \wedge \theta^2,$$

so that

$$dk_1 \wedge \theta^1 + k_1 \omega_1^2 \wedge \theta^2 = k_2 \omega_1^2 \wedge \theta^2.$$

Applying this to (X_1, X_2) , we find that

$$-X_2(k_1) = (k_2 - k_1) \cdot \omega_1^2(X_1).$$

Similarly, exterior differentiation of the equation $\psi_2^3 = k_2 \theta^2$ leads to

$$-X_1(k_2) = (k_2 - k_1) \cdot \omega_1^2(X_2).$$

Thus

$$(1) \quad \omega_1^2 = -\frac{X_2(k_1)}{k_2 - k_1} \theta^1 - \frac{X_1(k_2)}{k_2 - k_1} \theta^2.$$

Now consider a unit vector field

$$\alpha_1 X_1 + \alpha_2 X_2,$$

with

$$(2) \quad (\alpha_1)^2 + (\alpha_2)^2 = 1.$$

For this to be an asymptotic vector field we need

$$k_1(\alpha_1)^2 + k_2(\alpha_2)^2 = 0.$$

For simplicity we now take the case $K = -1$, so that $k_1 k_2 = -1$. Then $\alpha_1 X_1 + \alpha_2 X_2$ is asymptotic if and only if

$$\begin{aligned} (\alpha_2)^2 = -\frac{k_1}{k_2}(\alpha_1)^2 &\implies (\alpha_1)^2 - \frac{k_1}{k_2}(\alpha_1)^2 = 1 \quad \text{by (2)} \\ &\implies (\alpha_1)^2 = \frac{1}{1 - \frac{k_1}{k_2}} \\ &= \frac{1}{1 + k_1^2}, \quad \text{since } k_1 k_2 = -1. \end{aligned}$$

So our unit asymptotic vector fields must be

$$\begin{aligned} Y_1 &= \pm \alpha_1 X_1 \pm \alpha_2 X_2 \\ Y_2 &= \pm \alpha_1 X_1 \pm \alpha_2 X_2, \end{aligned}$$

where the α_i are given by

$$(3) \quad \alpha_i = \frac{1}{\sqrt{1 + k_i^2}}.$$

It is convenient to note that we can write equation (1) in terms of the α_i as

$$(4) \quad \omega_j^i = \frac{X_j(\alpha_i)}{\alpha_i} \theta^i - \frac{X_i(\alpha_j)}{\alpha_j} \theta^j.$$

Now to show that $[Y_1, Y_2] = 0$ we just need to show that $[\alpha_1 X_1, \alpha_2 X_2] = 0$. But we have (see pg. I.215)

$$\begin{aligned} \theta^i([\alpha_1 X_1, \alpha_2 X_2]) &= \alpha_1 X_1(\theta^i(\alpha_2 X_2)) - \alpha_2 X_2(\theta^i(\alpha_1 X_1)) - d\theta^i(\alpha_1 X_1, \alpha_2 X_2) \\ &= \delta_{i2} \alpha_1 X_1(\alpha_2) - \delta_{i1} \alpha_2 X_2(\alpha_1) + \sum_j (\omega_j^i \wedge \theta^j)(\alpha_1 X_1, \alpha_2 X_2) \\ &= \delta_{i2} \alpha_1 X_1(\alpha_2) - \delta_{i1} \alpha_2 X_2(\alpha_1) \\ &\quad + \delta_{i1} \alpha_2 X_2(\alpha_1) - \delta_{i2} \alpha_1 X_1(\alpha_2) \quad \text{using (4)} \\ &= 0. \quad \blacklozenge \end{aligned}$$

For any 2-dimensional Riemannian manifold M (not necessarily immersed in \mathbb{R}^3), an immersion $g: (a, b) \times (c, d) \rightarrow M$ is called a **Tschebyscheff net** if all parameter curves are parameterized by arclength. If we think of the domain $(a, b) \times (c, d)$ as a piece of cloth woven from fibres parallel to the axes, then the immersion g doesn't stretch any fibres. So the surface can be outfitted in a sexy tight fitting suit if we can find Tschebyscheff nets around each point (we might have to sew a lot of pieces together). Lemma 10 shows that this can always be done on a submanifold of \mathbb{R}^3 with constant negative curvature. The notion of a Tschebyscheff net is an intrinsic one, however, and our next result is also.

11. LEMMA. Let M be a 2-dimensional Riemannian manifold and $g: (a, b) \times (c, d) \rightarrow M$ a Tschebyscheff net. Define $\omega: (a, b) \times (c, d) \rightarrow \mathbb{R}$ as follows: $\omega(s_0, t_0)$ is the unique number with $0 < \omega(s_0, t_0) < \pi$ such that $\omega(s_0, t_0)$ is an angle between

$$\left. \frac{dg(s, t_0)}{ds} \right|_{s=s_0} \quad \text{and} \quad \left. \frac{dg(s_0, t)}{dt} \right|_{t=t_0}$$

Then ω satisfies the differential equation

$$\frac{\partial^2 \omega}{\partial s \partial t} = (-K) \sin \omega.$$

PROOF. We have $E = G = 1$, and

$$F = \cos \omega, \quad W = \sqrt{EG - F^2} = \sin \omega.$$

From the equation in Problem 4-13 we obtain

$$\begin{aligned} K &= \frac{1}{2W} \left[\frac{\partial}{\partial t} \left(\frac{F_1}{W} \right) + \frac{\partial}{\partial s} \left(\frac{F_2}{W} \right) \right] \\ &= \frac{1}{2W} \left[\frac{\partial}{\partial t} \left(\frac{-\sin \omega \frac{\partial \omega}{\partial s}}{W} \right) + \frac{\partial}{\partial s} \left(\frac{-\sin \omega \frac{\partial \omega}{\partial t}}{W} \right) \right] \\ &= \frac{1}{2 \sin \omega} \left[\frac{\partial}{\partial t} \left(-\frac{\partial \omega}{\partial s} \right) + \frac{\partial}{\partial s} \left(-\frac{\partial \omega}{\partial t} \right) \right] \\ &= -\frac{\frac{\partial^2 \omega}{\partial s \partial t}}{\sin \omega}. \quad \diamond \end{aligned}$$

We are now ready to prove the theorem, which still requires quite a bit of argument. We will use the term **asymptotic Tschebyscheff net** for a Tschebyscheff net of the sort constructed in Lemma 10, with all parameter curves being asymptotic curves.

12. THEOREM. A complete surface M with constant curvature $K = -1$ cannot be immersed in \mathbb{R}^3 .

PROOF. The proof depends on establishing two facts:

- (A) Suppose that M could be immersed in \mathbb{R}^3 . Then there would be a Tschebyscheff net $f: \mathbb{R}^2 \rightarrow M$, from the whole plane to M , and the function ω , defined on all of \mathbb{R}^2 , which gives the angle between the first and second parameter lines would satisfy

$$\frac{\partial^2 \omega}{\partial s \partial t} = \sin \omega, \quad 0 < \omega < \pi.$$

- (B) There is no function $\omega: \mathbb{R}^2 \rightarrow \mathbb{R}$ satisfying

$$\frac{\partial^2 \omega}{\partial s \partial t} = C \sin \omega, \quad 0 < \omega < \pi,$$

where $C > 0$ is any constant.

PROOF OF (A). Select a point $p_0 \in M$. Let $c: \mathbb{R} \rightarrow M$ be an asymptotic curve, parameterized by arclength, with $c(0) = p_0$; since c is locally an integral curve of a *unit* vector field, it can be defined on all of \mathbb{R} since M is complete [compare Problem 1-5(c)]. Let $X(0)$ be a unit asymptotic vector at p_0 which is linearly independent of $c'(0)$, and let $X(t)$ be the unique continuous vector field X along c such that $X(t) \in M_{c(t)}$ is a unit asymptotic vector linearly independent

of $c'(t)$. The vector field X along c is just a device to enable us to distinguish a direction for each parameter value of c . We now define $f: \mathbb{R}^2 \rightarrow M$ as follows:

$$f(s, t) = \gamma_s(t),$$

where γ_s is the unique asymptotic curve, parameterized by arclength, with $\gamma_s(0) = c(s)$ and $\gamma_s'(0) = X(s)$.

What we have to show is that each curve $s \mapsto f(s, t)$ is an asymptotic curve. This depends on the existence, as guaranteed by Lemma 10, of asymptotic Tschebyscheff nets $g: (-\varepsilon, \varepsilon) \times (-\varepsilon, \varepsilon) \rightarrow M$ around any point. From the very definition of f the following at least is clear:

Observation: If for some $t \in (-\varepsilon, \varepsilon)$ the parameter curve $s \mapsto g(s, t)$ lies along a parameter curve $s \mapsto f(s, \bar{t})$, then *all* parameter curves $s \mapsto g(s, t)$ lie along parameter curves of f .

Now for any (s_0, t_0) we can find a finite number of asymptotic Tschebyscheff nets g_1, \dots, g_k whose images cover $\{f(s_0, t): 0 \leq t \leq t_0\}$. Arranging the g_i as in the picture below, so that the images of consecutive ones overlap, noting that

$s \mapsto f(s, 0)$ is an asymptotic curve by definition, and applying the Observation repeatedly, we see that $s \mapsto f(s, t_0)$ is an asymptotic curve for s sufficiently close to s_0 , which is what we wanted.

Our equation for ω then follows immediately from Lemma 11.

PROOF OF (B). Suppose we had a function $\omega: \mathbb{R}^2 \rightarrow \mathbb{R}$ satisfying

$$(1) \quad \frac{\partial^2 \omega}{\partial s \partial t} = C \sin \omega, \quad 0 < \omega < \pi,$$

for a constant $C > 0$, and hence, in particular,

$$(2) \quad \frac{\partial^2 \omega}{\partial s \partial t} > 0.$$

This implies that $\partial \omega / \partial s$ is increasing as a function of t , so that

$$(3) \quad \frac{\partial \omega}{\partial s}(s, t) > \frac{\partial \omega}{\partial s}(s, 0) \quad \text{for } t > 0.$$

Consequently, for $t > 0$ we have

$$\int_a^b \frac{\partial \omega}{\partial s}(s, t) ds > \int_a^b \frac{\partial \omega}{\partial s}(s, 0) ds,$$

so that

$$(4) \quad \omega(b, t) - \omega(a, t) > \omega(b, 0) - \omega(a, 0) \quad \text{for } t > 0 \text{ and } a < b.$$

Now we can't have $\partial \omega / \partial s = 0$ everywhere, so we can assume (changing our coordinates by a translation) that $\partial \omega / \partial s(0, 0) \neq 0$. Since the function $(s, t) \mapsto \omega(-s, -t)$ also satisfies (1), we can even assume that $\partial \omega / \partial s(0, 0) > 0$. Choose three fixed numbers

$$(5) \quad 0 < s_1 < s_2 < s_3 \quad \text{with} \quad \frac{\partial \omega}{\partial s}(s, 0) > 0 \quad \text{for } 0 \leq s \leq s_3,$$

and let

$$\varepsilon = \min \begin{cases} \omega(s_3, 0) - \omega(s_2, 0) \\ \omega(s_1, 0) - \omega(0, 0). \end{cases}$$

Then for all $t > 0$ and all $s \in [0, s_3]$ we have the following:

$$\left. \begin{array}{l} \omega(s, t) \text{ is increasing in } s, \\ \omega(s_1, t) - \omega(0, t) > \varepsilon \\ \omega(s_3, t) - \omega(s_2, t) > \varepsilon \end{array} \right\}, \quad \begin{array}{l} \text{by (3) and (5)} \\ \text{by (4) and the definition of } \varepsilon \end{array}$$

$$0 < \omega(s, t) < \pi.$$

Putting these together, we conclude that

$$\varepsilon \leq \omega(s, t) \leq \pi - \varepsilon \quad \text{for } s \in [s_1, s_2] \text{ and } t \geq 0,$$

and hence

$$(6) \quad \sin \omega(s, t) \geq \sin \varepsilon \quad \text{for } s \in [s_1, s_2] \text{ and } t \geq 0.$$

But suppose we integrate equation (1) over the rectangle $[s_1, s_2] \times [0, T]$. We obtain

$$\begin{aligned} C \int_0^T \int_{s_1}^{s_2} \sin \omega(s, t) ds dt &= \int_0^T \int_{s_1}^{s_2} \frac{\partial^2 \omega}{\partial s \partial t} ds dt \\ &= [\omega(s_2, T) - \omega(s_1, T) - \omega(s_2, 0) + \omega(s_1, 0)], \end{aligned}$$

or

$$\begin{aligned} \omega(s_2, T) - \omega(s_1, T) &= \omega(s_2, 0) - \omega(s_1, 0) + C \int_0^T \int_{s_1}^{s_2} \sin \omega(s, t) ds dt \\ &\geq \omega(s_2, 0) - \omega(s_1, 0) + CT(s_2 - s_1) \sin \varepsilon, \quad \text{by (6).} \end{aligned}$$

Taking T large enough, we get a contradiction, since the left side is $< \pi$. ♦

For the second proof of Hilbert's theorem, we need an observation which follows directly from Lemma 11.

13. LEMMA (HAZZIDAKIS' FORMULA). Let M be a 2-dimensional Riemannian manifold of constant curvature $K < 0$, and let $g: (a, b) \times (c, d) \rightarrow M$ be a Tschebyscheff net. Then any quadrilateral Q formed by parameter curves has area

$$\begin{aligned} \text{area}(Q) &= \frac{1}{-K} \left(\sum_{i=1}^4 \alpha_i - 2\pi \right) \\ &\leq \frac{2\pi}{-K}, \end{aligned}$$

where $\alpha_i \in (0, \pi)$ are the interior angles of Q .

PROOF. Introducing the function ω of Lemma 11, we have

$$dA = W ds \wedge dt = \sin \omega ds \wedge dt$$

$$\sin \omega = \frac{1}{-K} \frac{\partial^2 \omega}{\partial s \partial t}.$$

So

$$\begin{aligned} \text{area}(Q) &= \int_Q dA = \int_Q \sin \omega ds \wedge dt \\ &= \frac{1}{-K} \int_Q \frac{\partial^2 \omega}{\partial s \partial t} ds \wedge dt \\ &= \frac{1}{-K} \int_{s_1}^{s_2} \int_{t_1}^{t_2} \frac{\partial^2 \omega}{\partial s \partial t} ds dt \\ &= \frac{1}{-K} [\omega(s_2, t_2) - \omega(s_1, t_2) - \omega(s_2, t_1) + \omega(s_1, t_1)] \\ &= \frac{1}{-K} [\alpha_3 - (\pi - \alpha_4) - (\pi - \alpha_2) + \alpha_1] \\ &= \frac{1}{-K} \left(\sum_{i=1}^4 \alpha_i - 2\pi \right). \diamond \end{aligned}$$

On the other hand, consider the upper half-plane $\mathcal{H}^2 \subset \mathbb{R}^2$ with the Riemannian metric

$$\langle \cdot, \cdot \rangle = \frac{dx \otimes dx + dy \otimes dy}{y^2}.$$

This is a complete 2-dimensional Riemannian manifold of constant curvature $K = -1$ (see pg. II.301 and Problem I.9-41). We have

$$E = G = \frac{1}{y^2} \quad F = 0$$

$$dA = \sqrt{EG - F^2} dx \wedge dy = \frac{1}{y^2} dx \wedge dy,$$

so the total area of \mathcal{H}^2 is

$$\int_{-\infty}^{\infty} \int_0^{\infty} \frac{1}{y^2} dy dx = \infty.$$

Thus Lemma 13 shows that we *cannot* parameterize all of \mathcal{H}^2 by a Tschebyscheff net. This is the basis of our second proof of

12. THEOREM. A complete surface M of constant curvature $K = -1$ cannot be immersed in \mathbb{R}^3 .

PROOF. As in the proof of Theorem 9, we can assume that M is simply-connected. Then (Problem 1-5) M is isometric to $(\mathcal{H}^2, \langle \cdot, \cdot \rangle)$.

We claim first that there are two linearly independent unit asymptotic vector fields Y_1, Y_2 defined *on all of* M . The proof uses the fact that M is simply-connected, and follows a standard procedure. We arbitrarily select $(Y_1(p_0), Y_2(p_0))$ for some $p_0 \in M$. Then for every curve $c: [0, 1] \rightarrow M$ with $c(0) = p_0$, there will be a unique possible continuous choice of $(Y_1(c(t)), Y_2(c(t)))$ for all $t \in [0, 1]$ which extends $(Y_1(p_0), Y_2(p_0))$. If \bar{c} is another such curve with corresponding

$(\bar{Y}_1(c(t)), \bar{Y}_2(c(t)))$, and if moreover $\bar{c}(1) = c(1) = q$, then $\bar{Y}_i(q) = Y_i(q)$; the proof uses the usual argument involving a contraction to the constant path at p_0 of the curve c followed by \bar{c} in the reverse direction. A nicer argument is the following. For each p there are 4 possible choices for $Y_1(p)$, and then 2 possible choices for $Y_2(p)$, thus 8 possible choices for $(Y_1(p), Y_2(p))$. The set of all such pairs, for all $p \in M$, obviously forms an 8-fold covering space of M . Since M is simply-connected, this covering space consists of 8 components; any component gives us the desired pair of vector fields.

We now claim that the Tschebyscheff net $f: \mathbb{R}^2 \rightarrow M$ which we constructed in the first proof is actually a *diffeomorphism*. To prove this, we first describe f a little differently. Let $\{\phi_t^i\}$ be the 1-parameter group of diffeomorphisms generated by Y_i (recall this means that $t \mapsto \phi_t^i(p)$ is the integral curve of Y_i through p , for each p); the ϕ_t^i can be defined for all $t \in \mathbb{R}$ since M is complete and Y_i are unit vector fields (as in our first proof). We now pick a point $p_0 \in M$ and define

$$(1) \quad f(s, t) = \phi_t^2(\phi_s^1(p_0)).$$

Since $[Y_1, Y_2] = 0$ (Lemma 10), the 1-parameter groups ϕ^1, ϕ^2 commute (Lemma I.5-13), so we easily find that

$$(2) \quad f(s + s', t + t') = \phi_{t'}^2(\phi_{s'}^1(f(s, t))).$$

We claim first that f is onto M . Otherwise, there is a point $q \notin f(\mathbb{R}^2)$ with q on the boundary of $f(\mathbb{R}^2)$. Now there is an asymptotic Tschebyscheff net $g: (-\varepsilon, \varepsilon) \times (-\varepsilon, \varepsilon) \rightarrow M$ with $g(0, 0) = q$, and there is some point $r \in$

$(\text{image } g) \cap f(\mathbb{R}^2)$. Then q must be of the form

$$\begin{aligned} q &= \phi_{t'}^2(\phi_{s'}^1(r)) && \text{for some } s', t' \\ &= \phi_{t'}^2(\phi_{s'}^1(f(s, t))) && \text{for some } s, t \\ &= f(s + s', t + t') && \text{by (2),} \end{aligned}$$

so actually $q \in f(\mathbb{R}^2)$, a contradiction.

Now we claim that $f: \mathbb{R}^2 \rightarrow M$ is actually a covering map. For any point $q \in M$, choose an asymptotic Tschebyscheff net $g: (-2\varepsilon, 2\varepsilon) \times (-2\varepsilon, 2\varepsilon) \rightarrow M$ with $g(0, 0) = q$ such that g is a diffeomorphism onto some open subset $V \subset M$. We can assume that the s [and t] parameter curves of g lie along the s [and t] parameter curves of f . Suppose that $(s, t) \in f^{-1}(q)$. Consider the map

$$\phi: V \rightarrow (s - 2\varepsilon, s + 2\varepsilon) \times (t - 2\varepsilon, t + 2\varepsilon) \subset \mathbb{R}^2$$

defined by

$$g(s', t') \mapsto (s + s', t + t').$$

Using equation (2), we see that $f: (s - 2\varepsilon, s + 2\varepsilon) \times (t - 2\varepsilon, t + 2\varepsilon) \rightarrow V$ is a diffeomorphism with inverse ϕ . Now let

$$W = g((-\varepsilon, \varepsilon) \times (-\varepsilon, \varepsilon))$$

and for each $(s, t) \in \mathbb{R}^2$ let

$$W_{(s,t)} = (s - \varepsilon, s + \varepsilon) \times (t - \varepsilon, t + \varepsilon).$$

We claim that

$$f^{-1}(W) = \bigcup_{(s,t) \in f^{-1}(q)} W_{(s,t)}.$$

In fact, if

$$(s, t) \in f^{-1}(W),$$

then we have

$$f(s, t) = g(s', t') \quad \text{for some } (s', t') \in (-\varepsilon, \varepsilon) \times (-\varepsilon, \varepsilon),$$

and by equation (2),

$$\begin{aligned} f(s - s', t - t') &= \phi_{-t'}^2(\phi_{-s'}^1(f(s, t))) \\ &= \phi_{-t'}^2(\phi_{-s'}^1(g(s', t'))) \\ &= q, \end{aligned}$$

which proves the claim. Since each of the $W_{(s,t)}$ is mapped diffeomorphically onto W , the proof that f is a covering map will be complete once we show that any two distinct such rectangles $W_{(s_1, t_1)}$ and $W_{(s_2, t_2)}$ are disjoint. Now if $W_{(s_1, t_1)} \cap W_{(s_2, t_2)} \neq \emptyset$, then

$$(s_2, t_2) \in (s_1 - 2\varepsilon, s_1 + 2\varepsilon) \times (t_1 - 2\varepsilon, t_1 + 2\varepsilon).$$

But we know that f is a diffeomorphism on this rectangle. Since $f(s_1, t_1) = q = f(s_2, t_2)$, this means that $(s_1, t_1) = (s_2, t_2)$, so that $W_{(s_1, t_1)}$ and $W_{(s_2, t_2)}$ are actually the same. Thus f is indeed a covering map.

Now by the simple-connectivity of M we conclude that f is actually a diffeomorphism. Consequently, we can exhaust M by quadrilaterals formed by the parameter curves of f . Lemma 13 then implies that M has area $\leq 2\pi$, while we computed that M has infinite area. This contradiction establishes the theorem. ♦

It is easy to find a complete surface $M \subset \mathbb{R}^3$ with non-constant curvature $K < 0$ everywhere—for example, the elliptic hyperboloid of one sheet has this property. But in this example K comes arbitrarily close to 0. In 1964, Efimov [1] proved, by a lengthy ingenious argument, using no particularly sophisticated machinery, that there are no complete surfaces $M \subset \mathbb{R}^3$ with curvature $K < 0$ bounded away from 0; an exposition of the proof may be found in Klotz [2].

CHAPTER 6

THE GAUSS-BONNET THEOREM AND RELATED TOPICS

In Volume II we presented Gauss' proof that if $\triangle ABC$ is a geodesic triangle on a surface with Gaussian curvature K , then

$$\int_{\triangle ABC} K dA = \angle A + \angle B + \angle C - \pi.$$

At that time we also cast a suspicious glance at Stokes' Theorem, which seemed to be lurking in the background, and promised to present a proof which would implicate it more fully. We are now in a position to redeem that pledge. It is almost a foregone conclusion that moving frames will play a leading role in the proceedings, since this is the only treatment of curvature in which differential forms appear explicitly. Actually, we are going to generalize Gauss' result, and in two quite different directions. On the one hand, we will allow polygons with any number of sides, and we will not require the sides to be geodesics. On the other hand, we will also have something to say about the integral of K over a whole surface. We begin much more modestly, however, with quite elementary considerations.

Suppose that $\mathbf{X} = (X_1, X_2)$ and $\mathbf{X}' = (X'_1, X'_2)$ are two orthonormal moving frames on a 2-dimensional Riemannian manifold M . We have already found the relationship between the matrices of 1-forms $\omega = (\omega_j^i)$ and $\omega' = (\omega_j'^i)$ associated to these moving frames: If $\mathbf{X}' = \mathbf{X} \cdot a$ for an orthonormal matrix function a , then (see pg. II.280) we have

$$(I) \quad \omega' = a^{-1} da + a^{-1} \omega a.$$

Of course, in a 2-dimensional manifold this relationship can be expressed much more simply. If $\mathbf{X}(p)$ and $\mathbf{X}'(p)$ are similarly oriented, then the matrix $a(p)$

is just

$$a(p) = \begin{pmatrix} \cos \theta(p) & \sin \theta(p) \\ -\sin \theta(p) & \cos \theta(p) \end{pmatrix},$$

where $\theta(p)$ is the oriented angle between $X_1(p)$ and $X'_1(p)$.

Usually we define the “angle” between two vectors to be a number between $-\pi$ and π , but then the function θ need not be continuous. Locally, we can make θ differentiable by allowing other values of θ . In the next result, it does not matter that this θ is not well-defined, because the form $d\theta$ still is.

1. PROPOSITION. Let X_1, X_2 and X'_1, X'_2 be two similarly oriented orthonormal moving frames on a 2-dimensional Riemannian manifold M , and let $\omega_1^2, \omega_1'^2$ be the corresponding connection forms. Let θ be a differentiable choice of the angle between X_1 and X'_1 . Then

$$\omega_1'^2 = \omega_1^2 + d\theta.$$

PROOF. It is easily checked that this is precisely what equation (1) comes down to. It is probably also a good exercise to derive the whole thing from scratch, using properties of ∇ , or by reproving Proposition II.7-14 for 2-manifolds. ♦

Now consider a curve $c: [a, b] \rightarrow M$ which lies in a region on which we have an orthonormal moving frame X_1, X_2 . Suppose that V is a unit vector field along c . We can then define the angle between V and X_1 in an even more precise manner, based on the constructions on pp. II.16–18. We first define a map $\alpha: [a, b] \rightarrow S^1$ by letting $\alpha(t)$ be the image of $V(t)$ under the unique linear map $M_{c(t)} \rightarrow \mathbb{R}^2$ which takes $X_1(c(t))$ to e_1 . We then have, by

Proposition II.1-5, a continuous map $\phi: [a, b] \rightarrow \mathbb{R}$ with

$$\alpha(t) = (\cos \phi(t), \sin \phi(t)),$$

and any two such maps differ by a multiple of 2π . We will refer to any such ϕ as a continuous choice of the angle between X_1 and V . It is easy to see that ϕ is actually C^∞ if V is a C^∞ vector field along c .

2. COROLLARY. Let M be a 2-dimensional Riemannian manifold, and let $c: [a, b] \rightarrow M$ be an immersed curve which lies in a region on which we have a positively oriented orthonormal moving frame X_1, X_2 . Let V be a C^∞ unit vector field along c , and let ϕ be a continuous choice of the angle between X_1 and V . Then V is parallel along c if and only if

$$\omega_1^2(c'(t)) + \phi'(t) = 0.$$

PROOF. Locally we can find an orthonormal moving frame X'_1, X'_2 oriented similarly to X_1, X_2 , with $X'_1 = V$ along c . We can choose the angle $\theta(p)$ between $X'_1(p)$ and $X_1(p)$ so that

$$\theta(c(t)) = \phi(t).$$

Then V is parallel along c if and only if

$$\begin{aligned} 0 &= \langle \nabla_{c'(t)} X'_1, X'_2 \rangle = \omega_1'^2(c'(t)) \\ &= \omega_1^2(c'(t)) + d\theta(c'(t)) \quad \text{by Proposition 1} \\ &= \omega_1^2(c'(t)) + (\theta \circ c)'(t) \\ &= \omega_1^2(c'(t)) + \phi'(t). \quad \spadesuit \end{aligned}$$

In Chapter 4 we defined the geodesic curvature κ_g of a curve c in an oriented surface $M \subset \mathbb{R}^3$. We also noted that κ_g is intrinsic. Indeed, for any arclength parameterized curve c in any Riemannian manifold $(M, \langle \cdot, \cdot \rangle)$ we can define κ_g (≥ 0) as the norm of $Dc'(s)/ds$; if M is an oriented 2-dimensional Riemannian manifold, then we defined the signed geodesic curvature κ_g by

$$\kappa_g(s) = \left\langle \frac{Dc'(s)}{ds}, \mathbf{u}(s) \right\rangle,$$

where $\mathbf{u}(s) \in M_{c(s)}$ is the unit vector perpendicular to $c'(s)$ with $(c'(s), \mathbf{u}(s))$ positively oriented.

3. COROLLARY. Let M be an oriented 2-dimensional Riemannian manifold, and let $c: [a, b] \rightarrow M$ be a curve, parameterized by arclength, which lies in a region on which we have a positively oriented orthonormal moving frame X_1, X_2 . Let ϕ be a continuous choice of the angle between X_1 and $c'(s)$. Then the signed geodesic curvature κ_g of c is given by

$$\kappa_g(s) = \omega_1^2(c'(s)) + \phi'(s).$$

PROOF. Locally we can find a positively oriented orthonormal moving frame X'_1, X'_2 with $X'_1 = c'$ along c . So we can choose the angle $\theta(p)$ between $X'_1(p)$ and $X_1(p)$ so that

$$\theta(c(s)) = \phi(s).$$

Then

$$\begin{aligned} \kappa_g(s) &= \langle \nabla_{X'_1} X'_1, X'_2 \rangle(c(s)) = \omega_1'^2(c'(s)) \\ &= \omega_1^2(c'(s)) + d\theta(c'(s)) \quad \text{by Proposition 1} \\ &= \omega_1^2(c'(s)) + \phi'(s). \quad \blacklozenge \end{aligned}$$

Each of our Corollaries can be used to obtain an interesting result. The first theorem partially fulfills a promise made on pg. II.243, for it gives a quantitative description of the fact that parallel translation along a closed curve generally does not bring a vector back to itself.

4. THEOREM. Let M be an oriented 2-dimensional Riemannian manifold, with Gaussian curvature K , and volume element dA . Let $N \subset M$ be a compact 2-dimensional manifold-with-boundary whose boundary ∂N is connected, let $c: [a, b] \rightarrow \partial N$ be a closed curve such that $c'(t)$ is positively oriented (with respect to the induced orientation on ∂N), and let V be a parallel unit vector field along c . If X_1, X_2 is a positively oriented moving frame defined on N , and $\phi: [a, b] \rightarrow \mathbb{R}$ is a continuous choice of the angle between X_1 and V , then

$$\phi(b) - \phi(a) = \int_N K dA.$$

PROOF. By the equations on page 69 we have

$$\begin{aligned}
 \int_N K dA &= \int_N K \theta^1 \wedge \theta^2 = - \int_N d\omega_1^2 \\
 &= - \int_{\partial N} \omega_1^2 \quad \text{by Stokes' Theorem} \\
 &= - \int_a^b \omega_1^2(c'(t)) dt \\
 &= \int_a^b \phi'(t) dt \quad \text{by Corollary 2} \\
 &= \phi(b) - \phi(a). \quad \spadesuit
 \end{aligned}$$

Notice that in order to measure the change in V effected by parallel translation, we made use of an orthonormal moving frame X_1, X_2 defined on all of N . Such a moving frame always exists, because a unit vector field X_1 exists on the *bounded* manifold N (see Problem I.11-13(e)), and X_2 is then determined by the orientation.

In our next theorem, the region N must be very special.

5. THEOREM. Let M be an oriented 2-dimensional Riemannian manifold, with Gaussian curvature K , and volume element dA . Let $N \subset M$ be a compact 2-dimensional manifold-with-boundary which is diffeomorphic to a subset of \mathbb{R}^2 , and whose boundary is connected. Let ds be the volume element of ∂N (determined by the induced Riemannian metric and induced orientation of ∂N), and let κ_g be the signed geodesic curvature of ∂N (on which we have a direction determined by the induced orientation). Then

$$\int_N K dA = - \int_{\partial N} \kappa_g ds + 2\pi.$$

PROOF. Because of our hypotheses on N , we might as well assume that M is an open subset of \mathbb{R}^2 . On M we define a positively oriented orthonormal moving frame X_1, X_2 by requiring X_1 to be a positive multiple of $\partial/\partial x^1$. Let $c: [a, b] \rightarrow \partial N$ be a closed curve, parameterized by arclength σ , such that $c'(\sigma)$ is positively oriented, and let ϕ be a continuous choice of the angle between X_1

and $c'(\sigma)$. Then

$$\begin{aligned}
 \int_N K \, dA &= \int_N K \theta^1 \wedge \theta^2 = - \int_N d\omega_1^2 = - \int_{\partial N} \omega_1^2 \\
 &= - \int_a^b \omega_1^2(c'(\sigma)) \, d\sigma \\
 &= - \int_a^b \kappa_g(\sigma) \, d\sigma + \int_a^b \phi'(\sigma) \, d\sigma \quad \text{by Corollary 3} \\
 &= - \int_{\partial N} \kappa_g \, ds + \phi(b) - \phi(a).
 \end{aligned}$$

To complete the proof, we have to show that $\phi(b) - \phi(a) = 2\pi$. This is done by noting three things.

- (1) The number $\phi(b) - \phi(a)$ is a multiple of 2π , since $\phi(b)$ and $\phi(a)$ are both choices of the angle for $c'(a) = c'(b)$.
- (2) Let $\langle \cdot, \cdot \rangle$ be the Riemannian metric on M , and let $\langle \cdot, \cdot \rangle$ be the usual Riemannian metric on \mathbb{R}^2 . It is easily checked that for each $t \in [0, 1]$, the tensor

$$\langle \cdot, \cdot \rangle^t = t \langle \cdot, \cdot \rangle + (1-t) \langle \cdot, \cdot \rangle$$

is also a Riemannian metric. Let X^t_1, X^t_2 be a positively oriented moving frame which is orthonormal with respect to $\langle \cdot, \cdot \rangle^t$, and for which X^t_1 is a positive multiple of $\partial/\partial x^1$; then let ϕ^t be a continuous choice of the angle between X^t_1 and $c'(\sigma)/\|c'(\sigma)\|^t$. The choice ϕ^t clearly depends continuously on t (if we make $\phi^t(a)$ vary continuously). Consequently, $\phi^t(b) - \phi^t(a)$ varies continuously with t . Since it is always a multiple of 2π , it must be constant.

- (3) When $t = 0$, we have $X^0_1 = \partial/\partial x^1$ and $X^0_2 = \partial/\partial x^2$, and consequently ϕ^0 is just a choice of the angle between the x -axis and c' . So $\phi^0(b) - \phi^0(a)$ is the total curvature of c , as defined on pg. II.18. By the *Hopf Umlaufsatz* (Theorem II.1-7), this total curvature is 2π . ♦

We would like to generalize Theorem 5 slightly, so that the boundary of N need not be smooth, but only piecewise smooth. The proof itself will go through almost precisely as before, and the real problem is to formulate the definitions and state the results correctly (something almost no one ever bothers to do). We will say that a compact 2-dimensional manifold-with-boundary $N \subset M$ is a **polygon** if ∂N is connected and if there is a simple closed curve $c: [a, b] \rightarrow N$ such that c is a smooth imbedding on each interval $[t_{i-1}, t_i]$ of some partition $a = t_0 < \dots < t_{n+1} = b$. Thus $c'(t)$ exists for all $t \neq t_i$, and the right and left hand derivatives $c'(t_i^+)$ and $c'(t_i^-)$ exist for all t_i . It will be convenient to work only with curves c such that $c'(b^-) = c'(a^+)$. The **vertices** of c will then

be t_1, \dots, t_n ; for each such vertex t_i , we would like to define its **interior angle** $\iota_i \in [0, 2\pi]$, as shown below. To do this, we first choose c so that $c'(t)$ is always

positively oriented. Let $v_1 = c'(t_i^+)$ and $v_2 = -c'(t_i^-)$. If v_1 and v_2 do not point in the same direction, we define

$\iota_i =$ oriented angle (between 0 and 2π) from v_1 to v_2 .

This still leaves us with the problem of defining ι_i when v_1 and v_2 point in the same direction. To treat this case, let $w_1(\varepsilon)$ be the tangent vector of the geodesic from $c(t_i)$ to $c(t_i + \varepsilon)$, and let $w_2(\varepsilon)$ be the tangent vector of the geodesic from $c(t_i)$ to $c(t_i - \varepsilon)$. For sufficiently small $\varepsilon > 0$, the vectors $w_1(\varepsilon)$

and $w_2(\varepsilon)$ are nearly in the same direction, so, in particular, they do not point in opposite directions. Therefore, the orientation of $(w_1(\varepsilon), w_2(\varepsilon))$ cannot change, since $w_1(\varepsilon)$ and $w_2(\varepsilon)$ are always distinct for small ε . We define ι_i to be 0 if $(w_1(\varepsilon), w_2(\varepsilon))$ is positively oriented, and 2π if it is negatively oriented. [The formula

$$\iota_i = \lim_{\varepsilon \rightarrow 0} \{\text{oriented angle from } w_1(\varepsilon) \text{ to } w_2(\varepsilon)\}$$

could be used as a general definition that would work in all cases.] Now that we have successfully defined the interior angle ι_i , we define the **discontinuity** δ_i of c' at t_i by

$$\delta_i = \pi - \iota_i \in [-\pi, \pi].$$

Remark: It is easy to see that if ϕ is an angle between $c'(t_i^-)$ and some vector $X \in M_{c(t_i)}$, then $\phi + \delta_i$ is an angle between $c'(t_i^+)$ and X .

6. THEOREM (THE GAUSS-BONNET FORMULA). Let M be an oriented 2-dimensional Riemannian manifold, with Gaussian curvature K , and volume element dA . Let $N \subset M$ be a polygon which is diffeomorphic to a subset of \mathbb{R}^2 , let ds be the volume element of ∂N , and let κ_g be its signed geodesic curvature. Suppose that ∂N has vertices t_1, \dots, t_n , with discontinuities $\delta_1, \dots, \delta_n$. Then

$$\begin{aligned} \int_N K dA &= - \int_{\partial N} \kappa_g ds - \sum_{i=1}^n \delta_i + 2\pi \\ &= - \int_{\partial N} \kappa_g ds + \sum_{i=1}^n \iota_i + (2 - n)\pi. \end{aligned}$$

PROOF. As in the proof of the previous theorem, we assume that M is an open subset of \mathbb{R}^2 , and we define X_1, X_2 exactly as before. Choose the curve $c: [a, b] \rightarrow \partial N$ to be parameterized by arclength σ , and so that $c'(\sigma)$ is positively oriented. By our Remark, we can choose $\phi_i: [t_{i-1}, t_i] \rightarrow \mathbb{R}$ so that each ϕ_i is a continuous choice of the angle between X_1 and $c'(\sigma)$ on (t_{i-1}, t_i) , and so that

$$(*) \quad \phi_{i+1}(t_i) - \phi_i(t_i) = \delta_i \quad i = 1, \dots, n.$$

Then

$$\begin{aligned}
 \int_N K dA &= \int_N K d\theta^1 \wedge d\theta^2 = - \int_N d\omega_1^2 = - \int_{\partial N} \omega_1^2 \\
 &= - \sum_{i=1}^{n+1} \int_{t_{i-1}}^{t_i} \omega_1^2(c'(\sigma)) d\sigma \\
 &= - \sum_{i=1}^{n+1} \left[\int_{t_{i-1}}^{t_i} \kappa_g(\sigma) d\sigma - \int_{t_{i-1}}^{t_i} \phi_i'(\sigma) d\sigma \right] \quad \text{by Corollary 3} \\
 &= - \int_{\partial N} \kappa_g ds + \sum_{i=1}^{n+1} \phi_i(t_i) - \phi_i(t_{i-1}) \\
 &= - \int_{\partial N} \kappa_g ds - \sum_{i=1}^n \delta_i + [\phi_{n+1}(b) - \phi_1(a)], \quad \text{using (*).}
 \end{aligned}$$

To complete the proof, we have to show that $\phi_{n+1}(b) - \phi_1(a) = 2\pi$. We do this by showing that the three observations in the previous proof now hold for $\phi_{n+1}(b) - \phi_1(a)$.

(1) and (2) are obvious.

(3) We are now dealing with a piecewise smooth simple closed curve c in \mathbb{R}^2 . We want to show that

$$2\pi = \phi_{n+1}(b) - \phi_1(a) = \sum_{i=1}^{n+1} \phi_i(t_i) - \phi_i(t_{i-1}) + \sum_{i=1}^n \delta_i.$$

To prove this generalization of the Hopf Umlaufsatz, we proceed as follows.

Draw a small circle C around $O = c(t_i)$. Let $P = c(\alpha_i)$ be the last point of $c|_{[t_{i-1}, t_i]}$ on C and let $Q = c(\beta_i)$ be the first point of $c|_{[t_i, t_{i+1}]}$ on C . The

oriented angle from \overrightarrow{OQ} to \overrightarrow{OP} approaches ι_i as the radius of C approaches 0. Also, the direction of $c'(\alpha_i)$ is nearly that of \overrightarrow{PO} , while the direction of $c'(\beta_i)$

is nearly that of \overrightarrow{OQ} . The picture below shows a curve c_i from P to Q which begins in the direction of $c'(\alpha_i)$, ends in the direction of $c'(\beta_i)$, and stays inside C except at P and Q . The total change in angle of the tangent vector c_i'

is easily seen to be very close to $\delta_i = \pi - \iota_i$. For each i , let us replace the portion of c between α_i and β_i by the curve c_i . If the circles C are small enough (so that curve does not enter the circle around $c(t_i)$ on any interval other than $[t_{i-1}, t_{i+1}]$), then the new curve, \tilde{c} , is simple. The total change in angle of the tangent vector \tilde{c}' is therefore 2π , by the Hopf Umlaufsatz. On the other hand, the total change along the portions c_i adds up to something very close to $\sum_i \delta_i$, while the total change along the other portions adds up to something very close to $\sum_i \phi_i(t_i) - \phi_i(t_{i-1})$. Therefore the number

$$\sum_{i=1}^{n+1} \phi_i(t_i) - \phi_i(t_{i-1}) + \sum_{i=1}^n \delta_i = \phi_{n+1}(b) - \phi_1(a)$$

must be close to 2π . Therefore it must be exactly 2π . ♦

7. COROLLARY. If the sides of the polygon N in Theorem 6 are geodesics, then

$$\int_N K dA = - \sum_{i=1}^n \delta_i + 2\pi = \sum_{i=1}^n \iota_i + (2 - n)\pi.$$

In particular, for a geodesic triangle we have

$$\int_N K dA = \iota_1 + \iota_2 + \iota_3 - \pi.$$

We are now in a position to find the integral of $K dA$ over all of M . The first method of doing this will use a triangulation $\{\sigma_i\}$ of M by 2-simplexes σ_i . Triangulations are defined in the “optional” Chapter 11 of Volume I (see pg. I.426),

and it is not easy to prove that they always exist on C^∞ manifolds; however, the proof for compact 2-manifolds is fairly easy (Problem 4-17). For a given triangulation of M we will let

V = number of 0-simplexes ("vertices")

E = number of 1-simplexes ("edges")

F = number of 2-simplexes ("faces").

The number

$$V - E + F = \chi(M)$$

is called the **Euler characteristic** of M . According to Theorem I.11-5, we have

$$\chi(M) = \dim H^0(M) - \dim H^1(M) + \dim H^2(M),$$

so actually $\chi(M)$ does not depend on the triangulation. However, it is not necessary to know this fact in order to follow the next proof.

8. THE GAUSS-BONNET THEOREM. Let M be a compact oriented 2-dimensional Riemannian manifold, with Gaussian curvature K , and volume element dA . Then

$$\int_M K dA = 2\pi \cdot \chi(M).$$

PROOF. Consider a triangulation $\sigma_1, \dots, \sigma_F$ of M . Let A_j, B_j, C_j be the three interior angles of σ_j . Then Theorem 6 gives

$$\begin{aligned} \int_M K dA &= \sum_{j=1}^F \int_{\sigma_j} K dA \\ &= \sum_{j=1}^F \left(\int_{\partial\sigma_j} \kappa_g ds \right) + \sum_{j=1}^F (A_j + B_j + C_j) - \sum_{j=1}^F 3\pi + \sum_{j=1}^F 2\pi. \end{aligned}$$

Now we note the following.

- (1) The sum $\sum \int \kappa_g ds$ is 0, because each edge of the triangulation appears twice, with opposite orientations.

- (2) The sum $\sum(A_j + B_j + C_j)$ is $2\pi V$, since the sum of all interior angles occurring at each vertex is exactly 2π .

- (3) The sum $-\sum 3\pi$ is just $-3F\pi$. On the other hand, we clearly have $3F = 2E$, since $3F$ is the total number of edges of all faces, each edge being counted twice since it is in two faces. So $-\sum 3\pi = 2\pi(-E)$.

- (4) The sum $\sum 2\pi$ is just $2\pi F$.

Therefore, our final sum is $2\pi(V - E + F) = 2\pi \cdot \chi(M)$. ♦

A whole slew of consequences follows immediately from this spectacular theorem, which expresses a differential-geometric quantity $\int_M K dA$ in terms of a number which has nothing at all to do with curvature, or even with a Riemannian metric. Note, first of all, that we can restate our result in a way which does not involve $\chi(M) = \dim H^0(M) - \dim H^1(M) + \dim H^2(M)$. We have shown that for *any* triangulation of M we have

$$\int_M K dA = 2\pi(V - E + F).$$

Picking a fixed triangulation, this shows that $\int_M K dA$ is independent of the metric. On the other hand, picking a fixed metric, we obtain an “elementary” proof, without using cohomology, that $V - E + F$ is independent of the triangulation.

The simplest consequences of the Gauss-Bonnet Theorem involve the sign of K on various compact oriented surfaces. All such surfaces are homeomorphic to the surface obtained by adding $g \geq 0$ handles to S^2 , and the Euler characteristic is then given by $\chi = 2 - 2g$. The latter result may be proved as

in Problem I.11-2, or by considering triangulations (we just have to check that $V - E + F$ changes by -2 when we add one more handle). Therefore,

$$\begin{aligned} \int_M K dA &> 0 \quad \text{if } M \text{ is homeomorphic to } S^2 \\ \int_M K dA &= 0 \quad \text{if } M \text{ is homeomorphic to a torus} \\ \int_M K dA &< 0 \quad \text{if } M \text{ is any other compact oriented surface.} \end{aligned}$$

It follows, in particular, that if there is a metric on a compact oriented 2-manifold M with $K > 0$ everywhere, then M must be homeomorphic to S^2 . This result is rather different from Theorem 2-11, because we do not assume that the metric comes from an imbedding in \mathbb{R}^3 (whether such a metric does, in fact, always come from an imbedding is a question which we will mention only later, in Chapter 11). On the other hand, if there is a metric on M with $K = 0$ everywhere, then M must be homeomorphic to the torus. As we have already seen (pg. II.179), such a flat metric does indeed exist on the torus. It is a good exercise to compute that $\int_M K dA = 0$ when M is the torus on page 159. Finally, if there is a metric on M with $K < 0$ everywhere, then M must be a sphere with $g \geq 2$ handles. Of course, we can never find an imbedding of such a surface M into \mathbb{R}^3 with $K < 0$ everywhere (by Proposition 2-8). But there is, nevertheless, an abstract Riemannian metric on M which has $K < 0$ everywhere; in fact, there is a Riemannian metric on M with $K = -1$ everywhere. The construction of such metrics is carried out in Addendum 1.

Our next consequence of the Gauss-Bonnet Theorem involves the notion of the index of a vector field, as defined in Chapter I.11.

9. THEOREM. Let M be a compact oriented 2-dimensional Riemannian manifold with Gaussian curvature K , and volume element dA . Let X be a vector field on M with only finitely many zeros. Then

$$\int_M K dA = 2\pi \cdot (\text{sum of indices of } X).$$

FIRST PROOF. We just combine the Gauss-Bonnet Theorem,

$$\int_M K dA = 2\pi \cdot \chi(M),$$

with the Poincaré-Hopf Theorem (I.11-30),

$$\chi(M) = \text{sum of indices of } X.$$

SECOND PROOF. This proof does not involve the intermediary $\chi(M)$, which appears nowhere in the statement of the theorem, nor will a triangulation be invoked. Let p_1, \dots, p_r be the zeros of X , and choose disjoint closed discs D_i containing p_i . Each D_i is diffeomorphic to $D = \{x \in \mathbb{R}^2 : |x| \leq 1\}$, and we will let $D_i(\varepsilon)$ denote the set corresponding to $\{x \in \mathbb{R}^2 : |x| \leq \varepsilon\}$. Let

$$N(\varepsilon) = M - (\bigcup_i \text{interior } D_i(\varepsilon)).$$

On $N(\varepsilon)$ there is a positively oriented orthonormal moving frame X_1, X_2 with $X_1 = X/\|X\|$. Then

$$\begin{aligned} \int_{N(\varepsilon)} K dA &= - \int_{N(\varepsilon)} d\omega_1^2 \\ &= - \sum_i \int_{\partial D_i(\varepsilon)} \omega_1^2 \quad \text{by Stokes' Theorem.} \end{aligned}$$

For the moment consider one particular i . Let X'_1, X'_2 be a fixed positively oriented orthonormal moving frame on D_i . On D_i minus a line segment we have a differentiable choice θ of the angle between X_1 and X'_1 , and by Proposition 1 we have

$$\begin{aligned} - \int_{\partial D_i(\varepsilon)} \omega_1^2 &= \int_{\partial D_i(\varepsilon)} d\theta - \int_{\partial D_i(\varepsilon)} \omega'^2_1 \\ &= (\text{index of } X \text{ at } p_i) - \int_{\partial D_i(\varepsilon)} \omega'^2_1 \\ &\quad [\text{where } \omega'^2_1 \text{ really depends on } i]. \end{aligned}$$

Therefore,

$$\lim_{\varepsilon \rightarrow 0} - \int_{\partial D_i(\varepsilon)} \omega_1^2 = (\text{index of } X \text{ at } p_i) - 0.$$

Consequently,

$$\int_M K dA = \lim_{\varepsilon \rightarrow 0} \int_{N(\varepsilon)} K dA = \sum_i \text{index of } X \text{ at } p_i. \spadesuit$$

Notice that the second proof of Theorem 9 reproves the fact that the sum of the indices of a vector field X is independent of X (it also reproves the fact that $\int_M K dA$ is independent of the metric). In conjunction with the proof of the Gauss-Bonnet Theorem, it reproves the fact that the sum of the indices of a vector field is $V - E + F$.

In contrast to the previous consequence of the Gauss-Bonnet Theorem, in which $\chi(M)$ does not appear, in the next consequence K does not appear.

10. THEOREM. Let $M \subset \mathbb{R}^3$ be a compact oriented 2-dimensional manifold, and let $\nu: M \rightarrow S^2$ be the normal map. Then

$$\text{degree of } \nu = \frac{\chi(M)}{2}.$$

PROOF. By the definition of $\deg \nu$ (pg. I.275), we have

$$\int_M \nu^* \omega = \deg \nu \cdot \int_{S^2} \omega$$

for all 2-forms ω on S^2 . Choosing ω to be the volume element da of S^2 , this means that

$$\begin{aligned} (4\pi) \deg \nu &= \int_M \nu^*(da) \\ &= \int_M K dA, \end{aligned}$$

where K is the curvature for the induced metric. Together with the Gauss-Bonnet Theorem, this yields the desired result. ♦

Just as in the case of Theorem 9, one would expect to find a proof of Theorem 10 which does not use the intermediary K . In fact, the same statement can be proved for hypersurfaces of \mathbb{R}^n , and this result played an important role in generalizing the Gauss-Bonnet Theorem to higher dimensions (see Chapter 13). Because the proof is differential-topological in nature, rather than differential-geometric, it has been shunted off to Addendum 2.

Our next result is merely a curiosity, an alternative proof of Theorem 2-11 which avoids covering spaces.

11. **PROPOSITION.** Let M be a compact connected 2-manifold, and let $f: M \rightarrow \mathbb{R}^3$ be an immersion with $K(p) > 0$ for all $p \in M$. Then M is orientable, the normal map $N: M \rightarrow S^2 \subset \mathbb{R}^3$ is a diffeomorphism, the map $f: M \rightarrow \mathbb{R}^3$ is an imbedding, and $f(M)$ is convex.

PROOF. Orientability of M is trivial, as in the proof of Theorem 2-11. The Gauss-Bonnet Theorem then shows that

$$2\pi \cdot \chi(M) = \int_M K \, dA > 0.$$

The only possibility is that M is homeomorphic to S^2 , with $\chi(M) = 2$; so

$$\int_M K \, dA = 4\pi.$$

Since $N(M) \subset S^2$ is closed (by compactness of M) and also open (as $K(p) \neq 0$ means that N is regular at p), the map N is onto S^2 . To prove that N is one-one, suppose instead that $N(p) = N(q)$ for some $p \neq q \in M$. Then there is an open set $U \ni q$ such that $N(M - \bar{U}) = S^2$. If da is the volume element on S^2 , then for any open set $V \subset M - \bar{U}$ on which N is one-one we have

$$\int_V K \, dA = \int_V N^*(da) = \int_{N(V)} da, \quad \text{since } N \text{ is orientation preserving.}$$

It follows that

$$\int_{M - \bar{U}} K \, dA \geq \int_{S^2} da = 4\pi.$$

Therefore

$$\int_M K \, dA = \int_{M - \bar{U}} K \, dA + \int_U K \, dA > 4\pi,$$

a contradiction. So N is one-one. The remainder of the proof is the same as for Theorem 2-11. ♦

Finally, here's a result that isn't about surfaces at all! (For a history of this result, see McCleary [1].)

12. **THEOREM (JACOBI; 1842).** Let c be a closed curve in \mathbb{R}^3 with nowhere vanishing curvature κ , and let \mathbf{n} be its normal map, into S^2 . If \mathbf{n} is a simple closed curve on S^2 , then it divides S^2 into two regions of equal area.

PROOF. Let B be one of the regions into which \mathbf{n} divides S^2 , and orient $c: [a, b] \rightarrow S^2$ so that the corresponding orientation for \mathbf{n} coincides with the induced orientation for ∂B . Theorem 5 gives

$$\int_B dA = - \int_{\partial B} \kappa_g d\sigma + 2\pi,$$

where κ_g is the geodesic curvature of \mathbf{n} on S^2 , and σ is the arclength function of \mathbf{n} . Since S^2 has area 4π , it suffices to prove that the integral of κ_g is 0. Now for any arclength parameterized curve γ on a surface M , the definition of its geodesic curvature κ_g is

$$\mathbf{T}\gamma'' = \kappa_g \cdot \nu \times \gamma',$$

where ν is the normal to M . This implies that

$$\kappa_g = \langle \gamma'', \nu \times \gamma' \rangle = \langle \gamma' \times \gamma'', \nu \rangle.$$

When γ is not parameterized by arclength, we have

$$\kappa_g(t) = \langle \gamma'(t) \times \gamma''(t), \nu(\gamma(t)) \rangle / |\gamma'(t)|^3.$$

Applying this to our curve \mathbf{n} on S^2 we obtain

$$\kappa_g(s) = \langle \mathbf{n}'(s) \times \mathbf{n}''(s), \mathbf{n}(s) \rangle / \left(\frac{d\sigma}{ds} \right)^3.$$

The Serret-Frenet formulas for c allow us to write this as

$$\kappa_g(s) = [\kappa(s)\tau'(s) - \kappa'(s)\tau(s)] / \left(\frac{d\sigma}{ds} \right)^3,$$

where κ and τ are the curvature and torsion of c . Now since

$$\mathbf{n}' = -\kappa\mathbf{t} + \tau\mathbf{b},$$

we have

$$\frac{d\sigma}{ds} = |\mathbf{n}'(s)| = \sqrt{\kappa^2(s) + \tau^2(s)}.$$

So

$$\begin{aligned} \kappa_g(s) &= \frac{\kappa\tau' - \kappa'\tau}{\kappa^2 + \tau^2} / \frac{d\sigma}{ds} = \frac{d}{ds} \left(\arctan \frac{\tau}{\kappa} \right) \frac{d\sigma}{ds} \\ &= \frac{d}{d\sigma} \left(\arctan \frac{\tau}{\kappa} \right). \end{aligned}$$

Since c is a closed curve, this gives

$$\int_{\partial B} \kappa_g d\sigma = \int_a^b d \left(\arctan \frac{\tau}{\kappa} \right) = 0. \quad \blacklozenge$$

We will conclude this Chapter with some considerations which, although they do not bear directly on the Gauss-Bonnet Theorem, are nevertheless related to the integral of the curvature. As we have already noted in the proof of Theorem 10, for an immersion $i: M \rightarrow \mathbb{R}^3$ of a compact oriented 2-manifold M into \mathbb{R}^3 , the integral of its curvature K is

$$\int_M K dA = (4\pi) \deg N,$$

where $N: M \rightarrow S^2$ is the normal map. This degree of N is simply the “signed” number of points in $N^{-1}(p)$ for any regular value $p \in S^2$ of N (Theorem I.8-12). Now let us consider the actual number $\#(p) \geq 0$ of points in $N^{-1}(p)$. We would like to look at

$$\int_{S^2} \# \cdot da,$$

where da is the volume element of S^2 ; for technical reasons we will instead consider

$$\int_{S^2-C} \# \cdot da,$$

where C is the set of critical values of N (which has measure 0 by Sard’s Theorem). Notice that for some $p \in S^2$ the set $N^{-1}(p)$ might be infinite; but such p are clearly contained in C and therefore do not bother us. Moreover, on $S^2 - C$ the function $\#$ is locally constant, so it is certainly continuous, and therefore the integral makes sense. Any point of $S^2 - C$ has a neighborhood U on which $\#$ has a constant value m and such that $N^{-1}(U) \subset M$ is the disjoint union of m open sets V_1, \dots, V_m on each of which $N: V_\alpha \rightarrow U$ is a diffeomorphism. Since $N^*(da) = K dA$, we have

$$\int_{V_\alpha} K dA = \begin{cases} \int_U da & N \text{ orientation preserving, i.e., } K > 0 \\ - \int_U da & N \text{ orientation reversing, i.e., } K < 0. \end{cases}$$

So

$$\int_{V_\alpha} |K| dA = \int_U da.$$

From this we readily see that

$$\int_M |K| dA = \int_{S^2-C} \# da.$$

This number is called the **total absolute curvature** of the immersion $i: M \rightarrow \mathbb{R}^3$.

13. THEOREM. For any immersion $i: M \rightarrow \mathbb{R}^3$ of a compact oriented 2-manifold in \mathbb{R}^3 , the total absolute curvature is $\geq 4\pi$. In fact,

$$\int_{\{p \in M: K(p) > 0\}} |K| dA = \int_{\{p \in M: K(p) > 0\}} K dA \geq 4\pi.$$

If the total absolute curvature of the immersion $i: M \rightarrow \mathbb{R}^3$ equals 4π , then i is an imbedding and $i(M)$ is convex.

PROOF. Let $M' = \{p \in M : K(p) \geq 0\}$. Since

$$\int_{\{p \in M: K(p) > 0\}} K dA = \int_{M'} K dA = \int_{M'} N^*(da),$$

the first part of the theorem will certainly be proved if we show that $N(M') = S^2$. For any $v \in S^2$, consider a plane $P \subset \mathbb{R}^3$ perpendicular to v and far away from $i(M)$ in the direction of v . Move this plane towards 0 until it first touches $i(M)$ at a point p . Then $N(p) = v$. Moreover, $K(p) \geq 0$, since M does not lie on both sides of its tangent plane P_0 at p . This proves the first part of the Theorem.

Now suppose that the total absolute curvature of the immersion $i: M \rightarrow \mathbb{R}^3$ equals 4π . We will first show that $i(M)$ lies on one side of each of its tangent planes. Suppose that M_p cuts $i(M)$, i.e., that $i(M)$ lies on both sides of its tangent plane M_p . The points furthest from M_p on each side will have normals which are negatives of each other and both perpendicular to M_p . Since $N(p)$ is also perpendicular to M_p , the point $v = N(p)$ has $\#(v) \geq 2$. It is clear that $i(M)$ also lies on both sides of the tangent planes M_q for q in a neighborhood U of p . Now if $K(p) \neq 0$, then we can also assume that n is a diffeomorphism on U , by making U smaller if necessary. Then $\# \geq 2$ on the whole open set $N(U)$. Since we have already shown that $\# \geq 1$ on S^2 , this shows that

$$\int_M |K| dA = \int_{S^2} \# da > 4\pi,$$

a contradiction. So to complete the proof that $i(M)$ lies on one side of M_p , we just have to show that if $K(p) = 0$, then there would be some other point \bar{p} such that $i(M)$ lies on both sides of $M_{\bar{p}}$, and also $K(\bar{p}) \neq 0$.

We will first find a point p' whose tangent plane cuts $i(M)$ and such that p' is not a planar point (i.e., either $K(p') \neq 0$ or p' is a parabolic point). There is certainly no problem doing this if there are non-planar points arbitrarily close

to p . So suppose that all points in a neighborhood of p are planar points; the image of this neighborhood under the immersion i then lies in M_p . Consider the set of all points in M whose image lies in M_p , and the component of this set which contains p . Let q be a boundary point of this component. Then $M_q = M_p$, so M_q also cuts $i(M)$. Moreover, q cannot have a whole neighborhood of planar points (for then it would not be a boundary point of the component). So there are points p' arbitrarily close to q such that p' is not a planar point. By choosing p' close enough, we can insure that $M_{p'}$ cuts $i(M)$.

If the point p' which we have produced satisfies $K(p') \neq 0$, we are done. Suppose instead that p' is a parabolic point. Let $L_{p'}$ be the straight line given by Corollary 5-6. Consider the set of points on $L_{p'}$ where $K = 0$; it is a certain closed interval I (which might be just $\{p'\}$). Along I the tangent plane of $i(M)$ is constant, by Proposition 4-5. So if q' is an endpoint of I , then $M_{q'} = M_{p'}$ cuts $i(M)$. Now q' cannot have a whole neighborhood of parabolic points, so there are points \bar{p} arbitrarily close to q' with $K(\bar{p}) \neq 0$. By choosing \bar{p} close enough, we can insure that $M_{\bar{p}}$ cuts $i(M)$.

Thus we have shown that $i(M)$ lies on one side of each of its tangent planes. Let $C \subset \mathbb{R}^3$ be the intersection of the closed half-spaces which are bounded by the planes M_p and contain the points of $i(M)$. Then C is a compact convex set with non-empty interior, and $i(M) \subset \text{boundary } C$. Since $i: M \rightarrow \mathbb{R}^3$ is an immersion, the set $i(M)$ is both open and closed in boundary C , hence $i(M) = \text{boundary } C$. By Problem 2-4, the map $i: M \rightarrow \text{boundary } C \approx S^2$ is a covering map. So i must be a homeomorphism. ♦

The first part of the preceding proof actually shows more than the asserted inequality, for we clearly have strict inequality if any open subset of S^2 is covered twice. Thus,

$$(*) \quad \int_{\{p \in M: K(p) > 0\}} K dA = 4\pi \iff N \text{ is one-one on } \{p \in M: K(p) > 0\}.$$

[Condition $(*)$ can also be expressed in terms of the total absolute curvature, for

$$\begin{aligned} \int_M |K| dA &= \int_{\{p \in M: K(p) > 0\}} K dA - \int_{\{p \in M: K(p) < 0\}} K dA \\ &= 2 \int_{\{p \in M: K(p) > 0\}} K dA - \int_M K dA \\ &\geq 8\pi - 2\pi \cdot \chi(M) \quad \text{by the Gauss-Bonnet Theorem,} \end{aligned}$$

with equality if and only if $(*)$ holds.] The pictures below illustrate some immersed surfaces with property $(*)$. In each case, the region of positive curvature

is a subset of a convex surface, bounded by convex plane curves. We will show, by elementary but involved arguments, that this is always so.

Given any set $X \subset \mathbb{R}^3$, let $H(X)$ be its convex hull, the smallest convex set containing X . Elementary considerations (Problem 1) show that if X is compact, then so is $H(X)$. For any unit vector $v \in S^2 \subset \mathbb{R}^3$, consider the subset of X where the function $\iota_v(x) = \langle x, v \rangle$ has its maximum value on X . This will be a subset of the plane P perpendicular to v which is furthest from the origin and still hits X . It is called the “topset” of X in the direction v , and is clearly a subset of the boundary $\partial H(X)$ of $H(X)$.

14. LEMMA. Let $i: M \rightarrow \mathbb{R}^3$ be an immersion of a compact oriented surface satisfying $(*)$. If $i(p) \in \partial H(i(M))$, then $K(p) \geq 0$; and conversely if we have the strict inequality $K(p) > 0$, then $i(p) \in \partial H(i(M))$.

PROOF. The first assertion is clear, since $i(M)$ has no support plane at $i(p)$ if $K(p) < 0$, while $H(i(M))$ has a support plane at every point of its boundary.

For each $v \in S^2$, consider the topset of $i(M)$ in the direction v . It is a closed convex subset of a plane. Suppose it contains at least 2 points $i(p_1), i(p_2)$ for $p_1, p_2 \in M$. We clearly have $K(p_1), K(p_2) \geq 0$. Condition (*) then shows that we must have either $K(p_1) = 0$ or $K(p_2) = 0$. Thus $v \in N(\{p \in M : K(p) = 0\}) = C$, say. In other words, if $v \in S^2 - C$, then the topset in the direction v contains only one point. This point of $\partial H(i(M))$ must be $i(p)$ for some $p \in M$, and clearly $N(p) = v$ and $K(p) \geq 0$. Thus

$$N(\{p \in M : i(p) \in \partial H(i(M)) \text{ and } K(p) \geq 0\}) \supset S^2 - C,$$

which has area 4π . So we cannot have $K(p) > 0$ for any other points $p \in M$. ♦

The main part of the argument goes into the following

15. LEMMA. Let $i: M \rightarrow \mathbb{R}^3$ be an immersion of a compact oriented surface satisfying (*). Then for any $v_1 \in S^2$, the topset of $i(M)$ in the direction v_1 is connected. Moreover, if $v_2 \in S^2$ is perpendicular to v_1 , then the topset in the direction v_2 of $\{\text{the topset of } i(M) \text{ in the direction } v_1\}$ is connected.

PROOF. If the topset in the direction v_1 is disconnected, then it is the disjoint union of two closed sets W_1, W_2 , which are also closed as subsets of $i(M)$, since the topset is a closed set. Let U_1, U_2 be disjoint open neighborhoods of W_1 and W_2 in $i(M)$. On the compact set ∂U_i we have $\langle x, v_1 \rangle$ strictly smaller than

the value of $\langle x, v_1 \rangle$ for $x \in W_i$. So the same is true for all $v \in S^2$ sufficiently

close to v_1 . This means that for all such v , the topset of U_i in the direction v contains a point $i(p) \in U_i$ not on the boundary of U_i . This implies that $v = N(p)$, and also that $K(p) \geq 0$. So for all v in a whole neighborhood of v_1 , with the exception of a set of measure 0, we have $v = N(p)$ where $i(p) \in U_i$ and $K(p) > 0$. Since the U_i are disjoint, this contradicts condition (*).

Now consider the topset in the direction v_2 of the topset of $i(M)$ in the direction v_1 ; say that ι_{v_2} has the value γ on this topset. Suppose this topset is disconnected and write it as the disjoint union of closed sets W_1 and W_2 . Choose U_1, U_2 to be disjoint open neighborhoods of W_1, W_2 in $i(M)$, and let

$$U_i^* = \{x \in U_i : \langle x, v_2 \rangle \geq \gamma\}.$$

One part of ∂U_i^* is the set

$$A_i = \partial U_i \cap \{x : \langle x, v_2 \rangle \geq \gamma\}$$

(indicated by a heavy line in the figure). On this compact set we have $\langle x, v_1 \rangle$ strictly smaller than the value $\langle x, v_1 \rangle$ for $x \in W_i$. So the same is true for all unit v close to v_1 . The other part of ∂U_i^* is

$$B_i = U_i \cap \{x : \langle x, v_2 \rangle = \gamma\}.$$

On this set, the function $\langle x, v_1 \rangle$ takes on its maximum at some $x \in W_i$. Suppose we choose our unit vector v in the plane spanned by v_1 and v_2 . Then for $x \in B_i$ we have

$$\langle x, v \rangle = (\text{constant}) \cdot \langle x, v_1 \rangle + \text{constant},$$

so the maximum still occurs on W_i . Thus, for a unit vector v_0 close enough to v_1 , and in the plane of v_1 and v_2 , the maximum of $\langle x, v_0 \rangle$ on ∂U_i^* occurs

at a point $x \in W_i$. Now we can choose a curve c in $i(M)$ with $c(0) = x$ and $c'(0) = v_2$, since the tangent plane at x is clearly the plane P which contains

the topset in the direction v_1 . If

$$v_0 = av_1 + bv_2, \quad a, b > 0,$$

then

$$\begin{aligned} \left. \frac{d}{dt} \right|_{t=0} \langle c(t), v_0 \rangle &= \langle c'(0), v_0 \rangle \\ &= \langle v_2, v_0 \rangle = b > 0. \end{aligned}$$

So $\langle c(t), v_0 \rangle$ has values greater than $\langle c(0), v_0 \rangle = \langle x, v_0 \rangle$ for small $t > 0$. This shows that the maximum of $\langle x, v_0 \rangle$ on U_i^* occurs at a point not on the boundary. Hence the same is true of $\langle x, v \rangle$ for all v sufficiently close to v_0 . As before, this leads to a contradiction. ♦

16. THEOREM. Let $i: M \rightarrow \mathbb{R}^3$ be an immersion of a compact oriented surface such that

$$\int_{\{p \in M: K(p) > 0\}} K \, dA = 4\pi.$$

Then there exist disjoint open sets U and V in M such that M is the union of U , V , and their common boundary; and such that

- (1) $K \geq 0$ on U and $K \leq 0$ on V .
- (2) $i: U \rightarrow i(U)$ is a diffeomorphism, and $i(U)$ is an open subset of the set $\partial H(i(M))$, bounded by a finite number of convex plane curves, each plane being the common tangent plane of $i(M)$ along the curve.

PROOF. Consider a topset of $i(M)$: it is of the form $P \cap M$ for some support plane P of $H(i(M))$, and $C = P \cap H(i(M))$ is a convex set. If this convex set contains only one point, then this point is in $i(M)$. If the convex set is a line

segment, then the endpoints must be in $i(M)$, so the whole segment must be in $i(M)$, by the first part of Lemma 15. Otherwise, the convex set is bounded by a curve Γ in P . We claim that all points of Γ are in $i(M)$. This is clear for all points of Γ which are extreme points of C (points which are not between other points of C). So the only possible exceptions are points on straight line segments of Γ . But the endpoints of such segments must be in $i(M)$, and then the whole segment must, by the second part of Lemma 15.

It is possible that Γ bounds a disc on $i(M)$, for the whole interior of Γ in P may be part of $i(M)$. But it is not possible that Γ is the boundary of a disc with $K \leq 0$ everywhere and $K < 0$ somewhere. For suppose it were. The disc D would be tangent to P along Γ . Let N be a surface tangent to P along Γ

such that the union of N and the disc which Γ bounds in P is convex. Then $N' = N \cup D$ is homeomorphic to S^2 , but

$$\begin{aligned} \int_{N'} K \, dA &= \int_N K \, dA + \int_D K \, dA \\ &= 4\pi + \int_D K \, dA \\ &< 4\pi, \end{aligned}$$

a contradiction. So if the interior of Γ is not part of $i(M)$, then Γ must be joined to a similar curve Γ' , or to several such curves. Since M is compact,

there can be only finitely many such curves $\Gamma_1, \dots, \Gamma_k$. Then $H(i(M))$ minus the discs bounded by $\Gamma_1, \dots, \Gamma_k$ can be taken to be $i(U)$. ♦

The study of total curvature (for submanifolds of Euclidean spaces in general) has recently grown into a little field of its own. However, almost all the results require methods from topology or Morse Theory, which are beyond our reach. We will end instead with a few somewhat older results concerning immersions $i: S^1 \rightarrow \mathbb{R}^3$, or equivalently, closed curves $c: [a, b] \rightarrow \mathbb{R}^3$. If c is parameterized by arclength, we define the **total curvature** of c to be

$$\int_a^b \kappa(s) ds = \int_a^b |\mathbf{t}(s)| ds = \text{length of the curve } \mathbf{t}: [a, b] \rightarrow S^2,$$

where $\kappa \geq 0$ is the ordinary curvature, and \mathbf{t} is the unit tangent vector. [This definition should not be confused with that given on pg. II.18, where we were concerned only with plane curves, and consequently allowed κ to be both positive and negative.] This total curvature can be related to the total absolute curvature of a certain surface M in \mathbb{R}^3 , the “canal surface” formed from the union of circles which bound discs of radius ε perpendicular to c (the Adden-

dum to Chapter I.9 can be used to show that M is an immersed surface for sufficiently small ε).

17. PROPOSITION. If M is a canal surface of the closed curve $c: [a, b] \rightarrow \mathbb{R}^3$, then

$$\int_a^b \kappa(s) ds = \frac{1}{4} \int_M |K| dA = \frac{1}{2} \int_{\{p \in M: K(p) > 0\}} K dA.$$

PROOF. Let $C = c([a, b])$ and $\varpi: M \rightarrow C$ the projection with $\varpi(p) = q$ when $p \in M$ is on the circle of radius ε perpendicular to C at q . Choose a unit vector field Z along C which is everywhere normal to C . On $M - \varepsilon \cdot Z$ we can

define a function ϕ , with values in $(0, 2\pi)$, giving the angle between p and Z on the circle $\varpi^{-1}(\varpi(p))$. If we regard the arclength s as a function on C (or $C - c(a)$, to be more rigorous), and also let s denote the function $s \circ \varpi$ on M , then (ϕ, s) is a coordinate system on M (minus a set of measure 0).

For each $p \in M$, let X_p be the unit vector tangent to the circle $\varpi^{-1}(\varpi(p))$ at p , and let Y_p be the unit vector at p which is parallel to the tangent vector dc/ds at $\varpi(p)$. The normal $N(p)$ at p points in the direction from $\varpi(p)$ to p

(Problem 2), so X_p and Y_p are tangent to M at p . It is easy to see that

$$\left. \begin{aligned} d\phi(X) &= 1 \\ ds(X) &= 0 \\ ds(Y) &= 1 \end{aligned} \right\} \implies d\phi \wedge ds(X, Y) = 1.$$

This shows that

$$d\phi \wedge ds = dA, \quad \text{the volume element on } M.$$

So

$$\int_M |K| dA = \int_M |K| d\phi \wedge ds = \int_a^b \left(\int_0^{2\pi} |K(\phi, s)| d\phi \right) ds.$$

Now

$$dN(X_p) = X_p, \quad \text{since } N \text{ is the identity map on the circle } \varpi^{-1}(\varpi(p)),$$

so if p has coordinates (ϕ, s) , then

$$\begin{aligned} \text{(I)} \quad K(\phi, s) &= -\langle dN(Y_p), Y_p \rangle = -\langle \nabla'_{Y_p} N, Y_p \rangle \\ &= \langle N(\phi, s), \nabla'_{Y_p} Y \rangle \quad \text{since } Y \text{ is a unit vector field} \\ &= \langle N(\phi, s), \kappa(s) \cdot \mathbf{n}(s) \rangle \\ &= \kappa(s) \cdot \{\text{cosine of the angle between } N(\phi, s) \text{ and } \mathbf{n}(s)\} \\ &= \kappa(s) \cdot \cos(\phi - \phi_0), \text{ say.} \end{aligned}$$

(When $\kappa(s) = 0$ and $\mathbf{n}(s)$ is undefined, this formula still holds, with an arbitrary choice of ϕ_0). Thus we have

$$\int_0^{2\pi} |K(\phi, s)| d\phi = \kappa(s) \int_0^{2\pi} |\cos(\phi - \phi_0)| d\phi = 4\kappa(s),$$

which shows that

$$\int_M |K| dA = \int_a^b 4\kappa(s) ds.$$

The second equality can easily be deduced from the fact that

$$\int_M K dA = 0,$$

which follows from the Gauss-Bonnet Theorem, since M is a torus. We can also deduce the result directly from equation (I), for if $\kappa(s) \neq 0$, then $K(\phi, s) \geq 0$ for $\cos(\phi - \phi_0) \geq 0$, and the integral of $\cos(\phi - \phi_0)$ over the subset of $[0, 2\pi]$ where it is ≥ 0 is exactly 2. ♦

18. COROLLARY (FENCHEL). The total curvature of any closed curve $c: [a, b] \rightarrow \mathbb{R}^3$ is $\geq 2\pi$. Equality holds if and only if c is a plane convex curve.

PROOF. The inequality follows directly from Theorem 13 and Proposition 17.

Now suppose that equality holds. In the proof of Theorem 13 we actually showed that

$$\int_{\tilde{M}} K dA \geq 4\pi,$$

where \tilde{M} is the set of all points $p \in M$ such that M lies on one side of M_p . We clearly also have

$$\int_{\tilde{\tilde{M}}} K dA \geq 4\pi,$$

where $\tilde{\tilde{M}} = \tilde{M} \cap \{p \in M : K(p) > 0\}$. Now if $\{p \in M : K(p) > 0\} - \tilde{\tilde{M}} \neq \emptyset$, then we would have

$$\int_{\{p \in M : K(p) > 0\}} K dA > 4\pi,$$

since $\tilde{\tilde{M}}$ is a closed subset of $\{p \in M : K(p) > 0\}$. This would contradict the assumption that the total curvature of c is 2π , by Proposition 17. So we see that

$$K(p) > 0 \implies M \text{ lies on one side of } M_p.$$

Now consider a point $c(s)$ with $\kappa(s) \neq 0$. On the circle $\varpi^{-1}(c(s))$ there is an open semi-circle with $K > 0$. At the two endpoints of this semi-circle the tangent planes P_1, P_2 of M are parallel. Moreover, M lies on one side of each of these planes, since the points are limits of points where $K > 0$, and hence of points p such that M lies on one side of M_p . So M lies entirely within the space between the parallel planes P_1, P_2 . These planes are at distance 2ε if M is the canal surface formed by discs of radius ε . We claim that C must lie entirely on the plane P midway between P_1 and P_2 . For consider a point $c(s)$ of C furthest

from P . The tangent vector $c'(s)$ must be parallel to P , which means that the

disc of radius ε through $c(s)$ and perpendicular to c is also perpendicular to P . But then some points of this disc will lie outside of the region bounded by P_1 and P_2 unless $c(s)$ is on P . Thus c is a plane curve. The proof that c is convex is left to the reader. ♦

This proof, due to Voss [1], is quite different from the original proof of Fenchel [1]. For the sake of completeness, we offer the following extremely simple proof of Horn [1], where references to many other proofs may be found.

SECOND PROOF. We claim that if the closed curve $\mathbf{t}: [a, b] \rightarrow S^2$ lies in a closed hemisphere of S^2 , then c must be a plane curve (this implies, moreover, that \mathbf{t} cannot lie in an open hemisphere). Indeed, suppose that \mathbf{t} lies in a closed hemisphere; without loss of generality we can assume that it is the northern hemisphere, so that the third component \mathbf{t}^3 of \mathbf{t} satisfies $\mathbf{t}^3 \geq 0$. Then

$$0 = c^3(b) - c^3(a) = \int_a^b \mathbf{t}^3(s) ds \geq 0,$$

which implies that $\mathbf{t}^3(s) = 0$ for all s , and hence c is a plane curve. We now appeal to a simple

19. LEMMA. If γ is a closed curve on S^2 of length $< 2\pi$, then γ is contained in some open hemisphere of S^2 ; if γ has length 2π , then γ is contained in some closed hemisphere.

PROOF. Choose points p, q on γ which divide it into two arcs, γ_1 and γ_2 , of equal length. Rotate γ so that the north pole $N = (0, 0, 1)$ lies on the midpoint of the shorter arc of the great circle joining p and q . If arc γ_1 intersects the

equator at some point, let $\bar{\gamma}_1$ be the arc from p to q which is symmetric to γ_1 with respect to N . Then the closed curve made up of γ_1 and $\bar{\gamma}_1$ has the same length as γ , and also *contains two antipodal points*. This shows that the length of γ

is $\geq 2\pi$, and strict inequality holds if γ_1 actually enters the southern hemisphere. Since the same considerations hold for the other arc γ_2 , the lemma is proved, and with it the Theorem. ♦

Our last result concerns knotted closed curves $c: [a, b] \rightarrow \mathbb{R}$. There are several possible ways to define when a closed curve is knotted; for our purposes it will be simplest to say that c is **unknotted** if $c([a, b])$ is the boundary of an imbedded disc, and **knotted** otherwise. The following closed curve is knotted, although proving this fact requires considerable work.

20. THEOREM (FARY, MILNOR). The total curvature of a knotted closed curve $c: [a, b] \rightarrow \mathbb{R}^3$ is $\geq 4\pi$.

PROOF. Suppose that the total curvature of c is $< 4\pi$. If M is a canal surface of c , then by Proposition 17

$$\int_M |K| dA < 16\pi \implies \int_{S^2} \# da < 16\pi,$$

where da is the volume element of S^2 . This means that some point $v \in S^2$ is the image of at most 3 points of M , which is equivalent to saying that $c'(s)$ is perpendicular to v for at most 3 values of s . For simplicity, say that $v = (0, 0, 1)$. Since

$$\langle v, c'(s) \rangle = \frac{d}{ds} \langle v, c(s) \rangle,$$

the function $s \mapsto \langle v, c(s) \rangle = (\text{height of } c(s) \text{ above } (x, y)\text{-plane})$ has derivative 0 for at most 3 values of s . Since the number of relative maxima or minima of the height function is even, there must be just one of each. Therefore the curve c must consist of two arcs joining the lowest and highest points, each arc having monotonically increasing height. Each plane parallel to the (x, y) -plane between these lowest and highest points intersects the curve in 2 points. Joining each such pair by the line segment between them, we obtain an imbedded disc whose boundary is the curve. ♦

ADDENDUM 1

COMPACT SURFACES WITH
CONSTANT NEGATIVE CURVATURE

In order to construct a Riemannian metric $\langle \cdot, \cdot \rangle$ with $K = -1$ on any compact surface M of genus $g \geq 2$, we first need to consider the standard topological way of obtaining these surfaces. For simplicity we will work only with the oriented ones. We have often used the fact that the torus, with genus $g = 1$, can be obtained by identifying sides of a square according to the scheme shown below.

In general, the “ g -holed torus”, with genus $g \geq 1$, can be obtained by identifying sides of a $4g$ -gon according to the following scheme:

If your powers of visualization are much better than mine, you may be able to literally see that this is the case. Otherwise, the following argument should convince you. The dashed line in the first figure below is a circle, because, as

a quick check shows, the required identifications of sides forces all vertices to be identified to one point. This circle divides the identification space into two parts. The right half of the figure shows that each part, together with the bounding circle, is homeomorphic to a torus with an open disc removed. So the identification space is homeomorphic to the space obtained by removing a disc from each of two tori, and then identifying the boundary circles; hence

it is a 2-holed torus. A similar argument can be used to treat the general case, by induction.

Now the flat metric on the torus is just obtained from the flat metric on the square by performing the required identifications. The fact that we actually get

a Riemannian metric on the identification space depends on two circumstances: first, the opposite sides are of equal length, and second, the sum of the angles at the four vertices is exactly 2π . It is the failure of this second condition in larger polygons which prevents us from getting a flat metric on the orientable surfaces of higher genus. For surfaces with $g > 1$ we will construct a metric with $K = -1$ by obtaining $4g$ -gons in the *non-Euclidean plane* whose angles add up to exactly 4π .

Our model for the non-Euclidean plane will be the Poincaré upper half-plane $\mathcal{H}^2 = \{(x, y) \in \mathbb{R}^2 : y > 0\}$ with the Riemannian metric

$$\langle \cdot, \cdot \rangle = \frac{dx \otimes dx + dy \otimes dy}{y^2};$$

this manifold has constant curvature $K = -1$ (compare Problem I.9-41 and

pg. II.301). It would be possible to check that if we define the “straight lines” of \mathcal{H}^2 to be the geodesics for $(\ , \)$, then the Poincaré upper half-plane satisfies the axioms for non-Euclidean geometry, and then conclude, by a theorem of non-Euclidean geometry, that the sum of the angles of a geodesic triangle is always $< \pi$. Happily, we can also reach this conclusion simply by applying the Gauss-Bonnet Formula. Indeed we find (Corollary 7) that for a geodesic triangle Δ with interior angles $\iota_1, \iota_2, \iota_3$ we have

$$\pi - (\iota_1 + \iota_2 + \iota_3) = - \int_{\Delta} -1 dA = \text{area}(\Delta) > 0.$$

This also shows us that small triangles are very close to Euclidean triangles: the sum $\iota_1 + \iota_2 + \iota_3$ can be made as close to π as we like. It follows that the interior angles of an n -gon can be made as close to $(n - 1)\pi$ as we like.

In contrast to the situation for small triangles, let us consider what happens when we take 2 fixed geodesic rays from a point P and join points far out on each of the two sides with a third geodesic. The figure below shows two geodesic rays, both of which are portions of circles or straight lines which meet the x -axis at right angles (Problem I.9-41). The dashed line is another geodesic

which “meets these at 0 angle”. Of course, this third geodesic doesn’t really meet either of the first two in \mathcal{H}^2 . But it is clear from this picture that if we take points P_1 and P_2 far enough out on the two original geodesics, then the angles θ_1 and θ_2 between the unique geodesic through P_1 and P_2 and our given geodesics can be made as small as we like.

Now let us take a point P in \mathcal{H}^2 , and draw $4g$ geodesic rays from P , the angle between two successive rays being $2\pi/4g$. For each $r > 0$, consider the equilateral $4g$ -sided geodesic polygon obtained by joining the points on these rays which are at distance r from P . Let $\Sigma(r)$ be the sum of the interior angles

of this polygon; clearly $\Sigma(r)$ is a continuous function of r . But we have seen that $\Sigma(r) \rightarrow 0$ as $r \rightarrow \infty$, while as $r \rightarrow 0$ we have $\Sigma(r) \rightarrow (4g - 1)\pi > 2\pi$ for $g \geq 2$. So if $g \geq 2$, then there is an r with $\Sigma(r) = 2\pi$. This gives us an equilateral $4g$ -gon with the sum of the interior angles $= 2\pi$. After identifying

pairs of sides according to the scheme on page 292, we then have a metric on the surface of genus g with constant curvature $K = -1$.

We add here some supplementary remarks which may be of interest to readers familiar with complex analysis. The necessary identification of pairs of sides can easily be accomplished by means of one-one complex analytic maps of \mathcal{H}^2 onto itself, and it is thus easy to see that M can be made into a Riemann surface (a complex manifold of complex dimension 1), meaning that there is a collec-

tion \mathcal{A} of homeomorphisms $f: U \rightarrow \mathbb{C} = \mathbb{R}^2$, from open subsets $U \subset M$ onto open subsets of \mathbb{C} , such that

- (i) the union of the domains of all $f \in \mathcal{A}$ covers M
- (ii) if $f: U \rightarrow \mathbb{C}$ and $g: V \rightarrow \mathbb{C}$ are in \mathcal{A} , then

$$g \circ f^{-1}: f(U \cap V) \rightarrow g(U \cap V)$$

is complex analytic.

[In fact, it is possible to establish even more. Since each vertex of our polygon has angle $2\pi/4g$, we can arrange exactly $4g$ polygons congruent to it around every vertex. The same construction can be carried out at the new vertices of the new polygons, and the construction can then be repeated indefinitely. In this way we arrive at a “tiling” of the hyperbolic plane by equilateral $4g$ -gons. The one-one complex analytic maps of \mathcal{H}^2 onto itself which are required for identifying the sides of our original polygon all preserve the tiling, and generate a group \mathcal{G} , with M homeomorphic to the quotient space $\mathcal{H}^2/\mathcal{G}$ obtained by identifying z and $g(z)$ for all $z \in \mathcal{H}^2$ and $g \in \mathcal{G}$. The map $\mathcal{H}^2 \rightarrow \mathcal{H}^2/\mathcal{G}$ defined by taking z into its equivalence class in $\mathcal{H}^2/\mathcal{G}$ is a covering map. Thus we obtain an explicit construction of a covering map $\pi: \mathcal{H}^2 \rightarrow M$, which shows that \mathcal{G} must be isomorphic to $\pi_1(M)$, and that the universal covering space of M is homeomorphic to \mathbb{R}^2 . (The latter fact could also have been deduced from purely topological considerations, since all simply-connected (paracompact) 2-manifolds are homeomorphic to either \mathbb{R}^2 or S^2 , and S^2 cannot be the universal covering space of M since S^2 is compact, while $\pi_1(M)$ is infinite.)]

There are also two other methods which we can use to put a complex manifold structure on M .

Method A. Choose an arbitrary Riemannian metric $\langle \cdot, \cdot \rangle$ for M . We recall (pg. II.296) that a map f between Riemannian manifolds is **conformal** if each f_* is angle preserving. For any point p of a 2-dimensional Riemannian manifold $(M, \langle \cdot, \cdot \rangle)$, there is a neighborhood U of p and a conformal diffeomorphism $f: U \rightarrow \mathbb{R}^2$ onto an open subset of \mathbb{R}^2 with its usual Riemannian metric; this fact was mentioned in Volume II, and a proof will be found in Addendum 1 to Chapter 9 of these Volumes. It is also an elementary fact (Problem 4-9) that a diffeomorphism $f: W \rightarrow \mathbb{C}$, from an open set $W \subset \mathbb{C}$ onto an open subset of \mathbb{C} , is complex analytic if and only if f is orientation preserving and conformal with respect to the usual metric on \mathbb{R}^2 . We can therefore define \mathcal{A} to be the collection of all conformal orientation preserving $f: U \rightarrow \mathbb{R}^2$; if $f, g \in \mathcal{A}$, then $g \circ f^{-1}$ is orientation preserving and conformal, so it is complex analytic.

Method B. This method involves the Riemann surface, including branch points, of a “complete analytic function”. From its definition, it is clear that this surface is a Riemann surface in the sense of being a complex manifold. On the other hand, the usual method for visualizing the Riemann surface of

$$\sqrt{(z-1)(z-2)\dots(z-2(g+1))}$$

is to take two copies of the Riemann sphere, make “cuts” from 1 to 2, from 3 to 4, \dots , and from $2g+1$ to $2g+2$, and identify the corresponding cuts in the

two different spheres. This is homeomorphic to the g -holed torus.

If we use one of these two methods for putting a complex manifold structure on a compact oriented surface M of genus $g \geq 2$, then we can give another construction of a metric on M with constant curvature $K = -1$, provided that we are willing to use yet more machinery. We consider the universal covering space $\pi: \tilde{M} \rightarrow M$, and give it the structure of a Riemann surface in the obvious way. Then M is the quotient of \tilde{M} by the group of covering transformations, each of which is a one-one complex analytic map of \tilde{M} onto itself. Now we expect that \tilde{M} is \mathcal{H}^2 (as we have already mentioned at the beginning of this whole discussion). We can establish this fact independently by using the “general uniformization theorem”, which tells us that the simply-connected Rie-

mann surface \tilde{M} must be analytically equivalent to either \mathbb{C} or the upper half-plane \mathcal{H}^2 . Now all one-one complex analytic maps of \mathbb{C} onto itself are of the form $z \mapsto az+b$. This group, and hence any subgroup, is abelian, while the fundamental group of M is non-abelian if it has genus > 2 . So if M is a compact surface of genus $g \geq 2$, then \tilde{M} is \mathcal{H}^2 . But the only one-one complex analytic maps of \mathcal{H}^2 onto itself are of the form $z \mapsto (az+b)/(cz+d)$, and (Problem I.9-47, or Problem 7-6) these maps are isometries of \mathcal{H}^2 with the metric $(dx \otimes dx + dy \otimes dy)/y^2$. Consequently, M has a metric $\langle \ , \ \rangle$ such that $\pi^*\langle \ , \ \rangle = (dx \otimes dx + dy \otimes dy)/y^2$; clearly $(M, \langle \ , \ \rangle)$ has constant curvature -1 .

ADDENDUM 2

THE DEGREE OF THE NORMAL MAP

Let $M \subset \mathbb{R}^m$ be a compact hypersurface with normal map $\nu: M \rightarrow S^{m-1}$; we want to show that the degree of ν is $\chi(M)/2$. We will actually prove a more general result, involving any compact orientable manifold $M^n \subset \mathbb{R}^m$. From the Addendum to Chapter I.9 we know that for sufficiently small $\varepsilon > 0$, the set $N = \{q \in \mathbb{R}^m : d(q, M) \leq \varepsilon\}$ is a compact m -dimensional manifold-with-boundary, which is a tubular neighborhood under a projection map $\pi: N \rightarrow M$. We give N the usual orientation and ∂N the induced orientation, so that the corresponding normal map $\nu: \partial N \rightarrow S^{m-1}$ is outward pointing. We will show that:

The degree of the normal map $\nu: \partial N \rightarrow S^{m-1}$ is $\chi(M)$.

[In the special case where $M \subset \mathbb{R}^m$ is a hypersurface, the manifold ∂N consists of two components each homeomorphic to M , and the degree of $\nu: \partial N \rightarrow S^{m-1}$ is just twice the degree of the normal map of M , so it will follow that this degree is $\chi(M)/2$.]

We will follow the exposition in Milnor [1]. The first step is a simple

21. LEMMA. Let $N \subset \mathbb{R}^m$ be a compact m -dimensional manifold-with-boundary, and let $\nu: \partial N \rightarrow S^{m-1}$ be the normal map. Let X be a vector field on N with isolated zeros, and suppose that X is outward pointing on ∂N . Then the degree of $\nu: \partial N \rightarrow S^{m-1}$ is equal to the sum of the indices of X .

PROOF. We regard X as a map $X: N \rightarrow \mathbb{R}^m$. Let p_1, \dots, p_k be the zeros of X , and let U_1, \dots, U_k be open ε -balls around p_1, \dots, p_k with all $\overline{U_i} \subset \text{interior } N$. Then $\mathcal{B} = N - (U_1 \cup \dots \cup U_k)$ is a compact manifold-with-boundary, and $\bar{X} = X/|X|: \mathcal{B} \rightarrow S^{m-1}$. Now if ω is any $(m-1)$ -form on S^{m-1} , then

$$\int_{\partial \mathcal{B}} \bar{X}^*(\omega) = (\text{degree } \bar{X}|_{\partial \mathcal{B}}) \cdot \int_{S^{m-1}} \omega.$$

By Stokes' Theorem we have

$$\int_{\partial \mathcal{B}} \bar{X}^*(\omega) = \int_{\mathcal{B}} d\bar{X}^*(\omega) = \int_{\mathcal{B}} \bar{X}^*(d\omega) = 0,$$

so the degree of $\bar{X}|_{\partial \mathcal{B}}$ must be 0. But $\bar{X}|_{\partial N}$ is smoothly homotopic to ν , while the degrees on the other components of $\partial \mathcal{B}$ are the negatives of the indices of X at the p_i (the minus signs come from the fact that the orientations on these components are the negatives of the usual ones). Thus

$$\deg \nu - (\text{sum of indices of } X \text{ at the } p_i) = 0. \quad \blacklozenge$$

Now suppose we have a compact oriented manifold $M^n \subset \mathbb{R}^m$ and we choose an arbitrary vector field X on M with only isolated zeros; according to the Poincaré-Hopf Theorem (I.11-30) the sum of its indices is $\chi(M)$. We can extend X to a vector field Y on the tubular neighborhood N in a rather obvious way, by defining

$$(*) \quad Y(p) = [p - \pi(p)] + X(\pi(p)) \quad (\text{considered as a vector at } p).$$

Since the normal $\nu(p)$ points in the direction from $\pi(p)$ to p (Problem 2), and the vector $p - \pi(p)$ is perpendicular to M_p , it is clear that Y points outward

along ∂N , and that the zeros of Y in all of N are precisely the zeros of X in M . If we could show that the index of Y at such a zero equals the index of X , then the desired result would follow from Lemma 21. However, a direct analysis of the index of Y turns out to be very difficult, so we take a slight detour.

Consider first a vector field X on \mathbb{R}^n , with an isolated zero at $0 \in \mathbb{R}^n$. We regard X as a function $X: \mathbb{R}^n \rightarrow \mathbb{R}^n$, and we define X to be **non-degenerate** at 0 if the derivative $DX(0): \mathbb{R}^n \rightarrow \mathbb{R}^n$ is non-singular.

22. LEMMA. If X has a non-degenerate zero at 0, then the index of X at 0 is $+1$ or -1 , depending on whether $\det DX(p) > 0$ or < 0 .

PROOF. We can assume $p = 0$. Then X is a diffeomorphism on some convex open neighborhood U of 0. In the proof of Lemma I.11-27 we saw that if X is orientation preserving, then X is smoothly homotopic to the identity via maps which have no zeros. So the index is 1. Similarly, if X reverses orientation, then it is smoothly homotopic to a reflection, and has index -1 . ♦

Now consider an oriented n -manifold M , and a vector field X on M with an isolated zero at $p \in M$. Let $f: U \rightarrow \mathbb{R}^n$ be an orientation preserving diffeomorphism, where $U \subset M$ is an open set containing p , and $f(p) = 0$. Then f_*X is a vector field on \mathbb{R}^n , and we define X to be **non-degenerate** at p if f_*X is non-degenerate at 0. If $M \subset \mathbb{R}^m$ is a submanifold of \mathbb{R}^m , and we regard

the vector field X on M as a function $X: M \rightarrow \mathbb{R}^m$, then $DX(p): \mathbb{R}^m \rightarrow \mathbb{R}^m$ will take M_p to M_p . In fact, for the function $X \circ f^{-1}: \mathbb{R}^n \rightarrow M$ we have $(X \circ f^{-1})_*: \mathbb{R}^n_0 \rightarrow M_p$; but $(f^{-1})_*(\mathbb{R}^n_0) = M_p$, while X_* is the same as DX on M_p . It is easy to see from Lemma 22 that if p is a non-degenerate 0, then the index of X at 0 is $+1$ or -1 , depending on whether $\det DX(p): M_p \rightarrow M_p$ is > 0 or < 0 .

23. THEOREM. Let $M^n \subset \mathbb{R}^m$ be a compact oriented manifold with a closed tubular neighborhood $\pi: N \rightarrow M$. Then the degree of the normal map $\nu: \partial N \rightarrow S^{m-1}$ is $\chi(M)$.

PROOF. We will show that there is a vector field X on M with only non-degenerate zeros. Assuming this fact for the moment, we use the vector field X to define a vector field Y on N by $(*)$. It is easy to see that for $p \in M$ we have

$$DY(p) = \begin{cases} DX(p) & \text{on } M_p \\ I & \text{on } M_p^\perp. \end{cases}$$

Therefore $\det DY(p) = \det DX(p): M_p \rightarrow M_p$. So the index of Y at a zero p equals the index of X at p . Then Lemma 21 implies that the degree of $\nu: \partial N \rightarrow S^{m-1}$ is the sum of the indices of X , which equals $\chi(M)$ by the Poincaré-Hopf Theorem.

To obtain the desired vector field on M , we first choose a vector field X with only finitely many (possibly degenerate) zeros (as on pp. I.449–450). It obviously suffices to show that for each zero p we can find a new vector field which equals X outside of a small neighborhood U of p , and has only non-degenerate zeros inside the neighborhood. It obviously suffices to work on \mathbb{R}^n . Given a neighborhood U of a zero $p \in \mathbb{R}^n$, let $f: \mathbb{R}^n \rightarrow [0, 1]$ be a C^∞ function which is 1 on an open set W with $p \in W \subset \overline{W} \subset U$, and 0 on $\mathbb{R}^n - U$. By Sard's Theorem, there is a regular value X_0 of X arbitrarily close to 0. Consider the vector field

$$\bar{X} = X - f \cdot X_0.$$

Within W this vector field is 0 only at points q with $X(q) = X_0$, so all zeros in W are non-degenerate; on the other hand, in $U - W$ there are no zeros at all if X_0 is sufficiently small. ♦

As a final remark, we note that if we choose U to be a closed manifold-with-boundary, then the sum of the indices of \bar{X} at zeros within U is just the degree of $\bar{X}/|\bar{X}|: \partial U \rightarrow S^{m-1}$, as in the proof of Lemma 21. But this map is

the map $X/|X|: \partial U \rightarrow S^{m-1}$, whose degree is, by definition, the index of X at p . So, without using the Poincaré-Hopf Theorem, we have reproved the fact that for any vector field X on M with only isolated zeros, the sum of its indices is a constant, namely $\deg v: \partial N \rightarrow S^{m-1}$. We could then identify this constant with $\chi(M)$ as we did in Chapter I.11, when we originally proved the Poincaré-Hopf Theorem.

PROBLEMS

1. Let $X \subset \mathbb{R}^m$ be any set.
 - (a) The convex hull $H(X)$ is the union of the convex hulls of all finite subsets of X .
 - (b) The convex hull of $m + 2$ points in \mathbb{R}^m is the union of the convex hulls of all its subsets of $m + 1$ points.
 - (c) If X is compact, then so is $H(X)$.
2. Prove the assertions about the normals to a canal surface on page 287, and the normals of the tubular neighborhood, on page 300, by using the argument in Problem 3-12. Also generalize the argument of Problem I.9-28.

TABLE OF CONTENTS

Although the chapters are not divided into sections,
except for the major subdivisions within Chapter 7,
the listing for each chapter gives some indication
which topics are treated, and on what pages.

CHAPTER 7. HIGHER DIMENSIONS AND CODIMENSIONS

A. THE GEOMETRY OF CONSTANT CURVATURE MANIFOLDS

The standard models of $S^n(K_0)$ and $H^n(K_0)$ in \mathbb{R}^{n+1}	1
Stereographic projection and the conformal model of H^n	5
Conformal maps of \mathbb{R}^n and the isometries of H^n	8
Totally geodesic submanifolds and geodesic spheres of H^n	10
Horospheres and equidistant hypersurfaces	14
Geodesic mappings; the projective model of H^n ; Beltrami's theorem	17

B. CURVES IN A RIEMANNIAN MANIFOLD

Frenet frames and curvatures	21
Curves whose j^{th} curvature vanish	27

C. THE FUNDAMENTAL EQUATIONS FOR SUBMANIFOLDS

The normal connection and the Weingarten equations	32
Second fundamental forms and normal fundamental forms; the Codazzi-Mainardi equations	35
The Ricci equations	38
The fundamental theorem for submanifolds of Euclidean space . . .	41
The fundamental theorem for submanifolds of constant curvature manifolds	50

D. FIRST CONSEQUENCES

The curvatures of a hypersurface; Theorema Egregium; formula for the Gaussian curvature	64
The mean curvature normal; umbilics; all-umbilic submanifolds of Euclidean space	71
All-umbilic submanifolds of constant curvature manifolds	75
Positive curvature and convexity	79

E. FURTHER RESULTS

Flat ruled surfaces in \mathbb{R}^m	85
Flat ruled surfaces in constant curvature manifolds	86
Curves on hypersurfaces	88

F. COMPLETE SURFACES OF CONSTANT CURVATURE

Modifications of results for surfaces in \mathbb{R}^3	91
Surfaces of constant curvature in S^3	93
surfaces with constant curvature 0	94
the Hopf map	107
Surfaces of constant curvature in H^3	110
Jörgens theorem; surfaces of constant curvature 0	112
surfaces of constant curvature -1	117
rotation surfaces of constant curvature between -1 and 0	118

G. HYPERSURFACES OF CONSTANT CURVATURE IN
HIGHER DIMENSIONS

Hypersurfaces of constant curvature in dimensions > 3	119
The Ricci tensor; Einstein spaces, hypersurfaces which are Einstein spaces	120
Hypersurfaces of the same constant curvature as the ambient manifold	123
Addendum 1. The Laplacian	128
Addendum 2. The $*$ operator and the Laplacian on forms; Hodge's Theorem	139
Addendum 3. When are two Riemannian manifolds isometric? . . .	152
Addendum 4. Better imbedding invariants	163
Problems	189

CHAPTER 8. THE SECOND VARIATION

Two-parameter variations; the second variation formula	201
Jacobi fields; conjugate points	208
Minimizing and non-minimizing geodesics	214
The Hadamard-Cartan Theorem	223
The Sturm Comparison Theorem; Bonnet's Theorem	226
Generalizations to higher dimensions; the Morse-Schoenberg Comparison Theorem; Meyer's Theorem; the Rauch Comparison Theorem	230

Synge's lemma; Synge's Theorem	239
Cut points; Klingenberg's theorem	246
Problems	258

CHAPTER 9. VARIATIONS OF LENGTH, AREA, AND VOLUME

Variation of area for normal variations of surfaces in \mathbb{R}^3 ; minimal surfaces	259
Isothermal coordinates on minimal surfaces; Bernstein's Theorem	264
Weierstrass-Enneper representation	268
Associated minimal surfaces; Schwarz's Theorem	274
Change of orientation; Henneberg's minimal surface	276
Classical calculus of variations in n dimensions	281
Variation of volume formula	286
Isoperimetric problems	293
Addendum 1. Isothermal coordinates	314
Addendum 2. Immersed spheres with constant mean curvature	347
Addendum 3. Imbedded surfaces with constant mean curvature	351
Addendum 4. The second variation of volume	355

CHAPTER 7

HIGHER DIMENSIONS AND CODIMENSIONS

The aim of this chapter is, roughly speaking, to see whether and how the results of the previous chapters generalize; instead of surfaces in \mathbb{R}^3 , we will be considering higher dimensional manifolds, of higher codimensions, imbedded or immersed in more general Riemannian manifolds. Even at the risk of making the chapter somewhat disorganized, I have tried to make it pretty complete, so that readers do not have to sit gnawing their thumbs wondering whether a generalization does not appear because it is trivial or because it is false, or because it is unknown. It should be mentioned, however, that a few diddly topics, like the Dupin indicatrix, aren't considered at all. In addition, a few points are taken up in later chapters, and the bibliography for appropriate sections should also be consulted. Finally, the most notable omission of all is the generalization of the Gauss-Bonnet Theorem, which occupies the place of honor in the last chapter of the book.

A. THE GEOMETRY OF CONSTANT CURVATURE MANIFOLDS

Although our aim in this chapter is to obtain results of the greatest possible generality, many of the theorems will not hold, or even make sense, unless the ambient manifold has constant curvature K_0 . It will be necessary for us to be as familiar with the properties of these Riemannian manifolds as we are with the case of Euclidean space ($K_0 = 0$). We will consider only the simply-connected complete n -dimensional Riemannian manifolds $(M, \langle \cdot, \cdot \rangle)$ of constant curvature K_0 ; by Problem 1-5, the manifold $(M, \langle \cdot, \cdot \rangle)$ is then uniquely determined up to isometry by K_0 .

For $K_0 > 0$, the manifold $(M, \langle \cdot, \cdot \rangle)$ is just the n -sphere $S^n(K_0)$ of radius $1/\sqrt{K_0}$ in \mathbb{R}^{n+1} ,

$$S^n(K_0) = \left\{ p \in \mathbb{R}^{n+1} : \langle p, p \rangle = \frac{1}{K_0} \right\},$$

with the Riemannian metric induced from the ordinary metric $\langle \cdot, \cdot \rangle$ of \mathbb{R}^{n+1} . For simplicity, we usually consider only the case $K_0 = 1$, setting $S^n = S^n(1)$.

It is clear that every orthogonal map $A \in O(n+1)$ takes S^n to itself and is an isometry. Moreover, $O(n+1)$ is precisely the set of isometries of S^n , since a suitable $A \in O(n+1)$ takes any orthonormal frame $X_1, \dots, X_n \in S^n_p$ at any point $p \in S^n$ to any other orthonormal frame $Y_1, \dots, Y_n \in S^n_q$ at any point $q \in S^n$, and an isometry of S^n is determined by its action on S^n_p (Problem 1-5).

For $K_0 < 0$, we can obtain an analogous submanifold of \mathbb{R}^{n+1} by considering a non-positive definite Riemannian metric on \mathbb{R}^{n+1} . Denoting the components of a point $a \in \mathbb{R}^{n+1}$ by a^0, a^1, \dots, a^n , we consider first the non-degenerate inner product $\langle \cdot, \cdot \rangle$ on \mathbb{R}^{n+1} defined by

$$\langle a, b \rangle = -a^0 b^0 + a^1 b^1 + \dots + a^n b^n.$$

This is called the **Lorentzian** inner product on \mathbb{R}^{n+1} , and the group $O^1(n+1)$ of all linear transformations $f: \mathbb{R}^{n+1} \rightarrow \mathbb{R}^{n+1}$ which preserve $\langle \cdot, \cdot \rangle$ is called the **Lorentz group** [actually (Problem 1), any map $f: \mathbb{R}^{n+1} \rightarrow \mathbb{R}^{n+1}$ preserving $\langle \cdot, \cdot \rangle$ is automatically linear]. By means of the standard identification of \mathbb{R}^{n+1}_p with \mathbb{R}^{n+1} , we obtain a non-degenerate inner product $\langle \cdot, \cdot \rangle_p$ on each \mathbb{R}^{n+1}_p , and thus a non-positive definite Riemannian metric on \mathbb{R}^{n+1} , which we denote also simply by $\langle \cdot, \cdot \rangle$. In terms of the standard coordinate system x^0, x^1, \dots, x^n on \mathbb{R}^{n+1} we have

$$\langle \cdot, \cdot \rangle = -dx^0 \otimes dx^0 + dx^1 \otimes dx^1 + \dots + dx^n \otimes dx^n.$$

The isometries of $(\mathbb{R}^{n+1}, \langle \cdot, \cdot \rangle)$ are (Problem 2) precisely the maps of the form

$$p \mapsto A(p) + q \quad A \in O^1(n+1), \quad q \in \mathbb{R}^{n+1}.$$

Now for $K_0 < 0$ consider the quadric hypersurface

$$\left\{ p \in \mathbb{R}^{n+1} : \langle p, p \rangle = \frac{1}{K_0} \right\}.$$

As illustrated on the next page, this consists of two components, each homeomorphic to \mathbb{R}^n ; we will pick one of them, say the one consisting of points with $p^0 > 0$, and define

$$H^n(K_0) = \left\{ p \in \mathbb{R}^{n+1} : p^0 > 0 \text{ and } \langle p, p \rangle = \frac{1}{K_0} \right\}.$$

For simplicity, we usually consider only the case $K_0 = -1$, setting $H^n(-1) = H^n$, the “ n -dimensional hyperbolic space”. To find the tangent space H^n_p , we proceed precisely as in the case of S^n . Any curve c in H^n satisfies

$$\langle c(t), c(t) \rangle = 0 \text{ for all } t \implies \langle c'(t), c(t) \rangle = 0,$$

so H_p^n contains only vectors v_p with $\langle v, p \rangle = 0$. Moreover, $\{v : \langle v, p \rangle = 0\}$ is the kernel of the non-zero linear functional $v \mapsto \langle v, p \rangle$, so it has dimension exactly $n - 1$. Thus

$$H_p^n = \{v_p : \langle v, p \rangle = 0\} \quad \text{for } p \in H^n, \quad \text{i.e., } \langle p, p \rangle = -1.$$

We now claim that the induced Riemannian metric on H^n is positive definite. To show this, it is convenient to consider the **index** of a bilinear function $B: V \times V \rightarrow \mathbb{R}$ on a vector space V , which is defined to be the largest dimension of any subspace $W \subset V$ on which B is negative definite [that is, $B(w, w) < 0$ for all $0 \neq w \in W$]. The bilinear function

$$(a, b) \mapsto \langle a, b \rangle = -a^0 b^0 + a^1 b^1 + \cdots + a^n b^n$$

on \mathbb{R}^{n+1} clearly has index ≥ 1 , for it is negative definite on the subspace $U^- = \{(a^0, 0, \dots, 0)\}$. Moreover, $\langle \cdot, \cdot \rangle$ is positive definite on the subspace $U^+ = \{(0, a^1, \dots, a^n)\}$. If $\langle \cdot, \cdot \rangle$ were negative definite on a subspace W of dimension ≥ 2 , then $\langle \cdot, \cdot \rangle$ would be negative definite on the non-zero subspace $W \cap U^+$, which is clearly impossible. So $\langle \cdot, \cdot \rangle$ has index 1. Naturally, each $\langle \cdot, \cdot \rangle_p$ also has index 1. Now consider $\langle \cdot, \cdot \rangle_p$ on H_p^n . If $v_p \in H_p^n$, then v is linearly independent of p , and we already have $\langle p, p \rangle < 0$, so we cannot have $\langle v, v \rangle < 0$, as $\langle \cdot, \cdot \rangle$ has index 1. Nor can we even have $\langle v, v \rangle = 0$, for then we would have

$$\langle p + v, p + v \rangle = \langle p, p \rangle + 2\langle p, v \rangle + \langle v, v \rangle = \langle p, p \rangle < 0,$$

which is also impossible. Thus $\langle \cdot, \cdot \rangle_p$ is positive definite on H^n_p , and H^n is an ordinary Riemannian manifold. (In the picture on the previous page this is quite clear, since all tangent lines have greater slope than the generators of the cone $\sum_i (x^i)^2 = (x^0)^2$, and a vector v along one of these generators satisfies $\langle v, v \rangle = 0$.)

Naturally every element of $O^1(n+1)$ which keeps $\{p \in \mathbb{R}^{n+1} : p^0 > 0\}$ fixed will give an isometry of H^n onto itself. We also claim that all isometries of H^n arise in this way. To prove this, we just note that if $(v_1)_p, \dots, (v_n)_p \in H^n_p$ is orthonormal, and similarly for $(w_1)_q, \dots, (w_n)_q \in H^n_q$, so that

$$\begin{aligned}\langle p, p \rangle &= \langle q, q \rangle = -1 \\ \langle v_i, p \rangle &= 0 = \langle w_i, q \rangle \\ \langle v_i, v_j \rangle &= \langle w_i, w_j \rangle = \delta_{ij},\end{aligned}$$

then the linear transformation taking

$$p \mapsto q \quad \text{and} \quad v_i \mapsto w_i$$

is clearly in $O^1(n+1)$. Since there are thus isometries of H^n taking any orthonormal basis at any point to any orthonormal basis at any other point, H^n must have constant curvature. We can compute that $H^n(K_0)$ has constant curvature K_0 in a manner exactly analogous to a computation of the curvature of $S^n(K_0)$, by using Theorems 1-1, 1-6, and 1-9; the only difference is that we must allow the ambient manifold in Theorems 1-1 and 1-6 to have a non-positive definite Riemannian metric, and the “unit” normal field v in 1-9 will actually satisfy $\langle v, v \rangle = -1$. The manifold $H^n(K_0)$ is (geodesically) complete. Because we are dealing with an indefinite metric on \mathbb{R}^{n+1} , this does not simply follow from the fact that $H^n(K_0)$ is a closed subset of \mathbb{R}^{n+1} . However, it is an easy exercise to prove completeness using the fact that there are isometries taking any orthonormal basis to any other. We also mention that the geodesics of H^n are (Problem 3) precisely the intersections $H^n \cap P$ where P is a plane in \mathbb{R}^{n+1} through 0; more generally, the totally geodesic submanifolds of H^n are $H^n \cap P$ where P is a vector subspace of \mathbb{R}^{n+1} .

In the past we have given several other models for H^n , and for S^n minus a point. For example, we have described the metric of a space of constant curvature K_0 in terms of normal coordinates, in Addendum 1 to Chapter II.7. In Addendum 2 to that chapter we found the most general isothermal coordinate systems on the manifolds of constant curvature, after first determining the expression for the metric on S^n in the coordinate system defined by “stereographic projection”. To define this map, we considered S^n as the sphere of radius 1

around the point $(0, \dots, 0, 1)$, so that S^n is tangent to $\mathbb{R}^n = \mathbb{R}^n \times \{0\} \subset \mathbb{R}^{n+1}$. Letting $*$ be the “north pole” $* = (0, \dots, 0, 2) \in S^n$, the **stereographic projection**

$$\sigma: S^n - \{*\} \rightarrow \mathbb{R}^n$$

is defined geometrically as follows: for any $p \neq *$ in S^n , we let $\sigma(p)$ be the point where the line between p and $*$ intersects \mathbb{R}^n . It is easy to check (see the

figure on the right) that

$$(1) \quad \sigma(p) = \left(\frac{2p^1}{2 - p^{n+1}}, \dots, \frac{2p^n}{2 - p^{n+1}} \right)$$

and that $f = \sigma^{-1}$ is given by

$$(2) \quad \sigma^{-1}(y) = f(y) = \left(\frac{y^1}{1 + \frac{1}{4} \sum_i (y^i)^2}, \dots, \frac{y^n}{1 + \frac{1}{4} \sum_i (y^i)^2}, \frac{\frac{1}{2} \sum_i (y^i)^2}{1 + \frac{1}{4} \sum_i (y^i)^2} \right).$$

If y^1, \dots, y^n denotes the standard coordinate system on \mathbb{R}^n , then the $y^i \circ \sigma$ give a coordinate system on $S^n - \{*\}$. We can compute the metric $\langle \cdot, \cdot \rangle$ in terms of this coordinate system by computing

$$\begin{aligned} f^* \sum_{i=1}^{n+1} dx^i \otimes dx^i &= \sum_{i=1}^{n+1} df^i \otimes df^i \\ &= \sum_{i=1}^{n+1} \sum_{j,k=1}^n \frac{\partial f^i}{\partial y^j} \frac{\partial f^i}{\partial y^k} dy^j \otimes dy^k, \end{aligned}$$

by means of equation (2).

However we can save ourselves a lot of computational work by first proving geometrically that σ is conformal. It clearly suffices to consider the case $n = 2$.

Notice first that if $L \subset \mathbb{R}^2$ is a straight line, then the lines through $*$ and points of L form a plane with a horizontal line through $*$ deleted, so $\sigma^{-1}(L)$ is $\Sigma - \{*\}$ for some circle $\Sigma \subset S^2$. Now given two linearly independent vectors $X_1, X_2 \in S^2_p$, consider the straight lines L_1, L_2 through $\sigma(p)$ pointing in the directions of $\sigma_*(X_1)$ and $\sigma_*(X_2)$. Their inverse images under σ are $\Sigma_1 - \{*\}$

and $\Sigma_2 - \{*\}$ for two circles $\Sigma_1, \Sigma_2 \subset S^2$ containing $*$. The angle between X_1 and X_2 is the angle of intersection of Σ_1 and Σ_2 at p , which is the same as the angle of intersection of Σ_1 and Σ_2 at $*$. But the tangent lines to Σ_1 and Σ_2 at $*$ are parallel to L_1 and L_2 , respectively. So the angle of intersection at $*$ is the same as the angle between σ_*X_1 and σ_*X_2 . Thus, σ is conformal.

Now for any point $y \in \mathbb{R}^n$, let $c: [0, 2\pi] \rightarrow \mathbb{R}^n$ be a curve, parameterized proportionally to arclength, which goes once around a circle centered at 0 and passing through y ; thus c' always has squared length $|y|^2$. Formula (2) shows

that $(\sigma^{-1} \circ c)'$ always has squared length

$$\sum_{i=1}^n \left[\frac{y^i}{1 + \frac{1}{4} \sum_i (y^i)^2} \right]^2 = \frac{|y|^2}{\left[1 + \frac{1}{4} \sum_i (y^i)^2 \right]^2}.$$

This shows that in the conformal coordinate system $\{x^i = y^i \circ \sigma\}$ on $S^n - \{*\}$, the metric $\langle \cdot, \cdot \rangle$ has the form

$$(3) \quad \langle \cdot, \cdot \rangle = \sum_{i=1}^n \frac{dx^i \otimes dx^i}{\left[1 + \frac{1}{4} \sum_i (x^i)^2\right]^2}.$$

If we were dealing with a sphere of curvature K_0 , the factor $1/4$ would be replaced by $K_0/4$.

For later use, we mention one further property of the stereographic projection: it takes spheres in S^n to spheres and hyperplanes of \mathbb{R}^n , and *vice-versa*. Indeed, a sphere $\Sigma \subset S^n$ is the intersection of S^n with some hyperplane,

$$\Sigma = \left\{ p \in S^n : \sum_{i=1}^{n+1} \alpha_i p^i = \beta \right\},$$

and then

$$\begin{aligned} y \in \sigma(\Sigma) &\iff \sigma^{-1}(y) \in \Sigma \\ &\iff \sum_{i=1}^n \alpha_i \frac{y^i}{1 + \frac{1}{4} \sum_i (y^i)^2} + \frac{1}{2} \alpha_{n+1} \frac{\sum_i (y^i)^2}{1 + \frac{1}{4} \sum_i (y^i)^2} = \beta, \quad \text{by (2).} \end{aligned}$$

This is always a sphere or hyperplane in \mathbb{R}^n , and the converse works similarly.

Now for $K_0 < 0$, in particular for $K_0 = -1$, we can just formally replace the factor $1/4$ in (3) by $-1/4$. In Addendum 2 to Chapter II.7 we showed that this metric does indeed have $K_0 = -1$. In fact, this metric was simply one possible choice for the conformal metrics of constant curvature $K_0 = -1$.

We have already pointed out that, in order to have a connected manifold, we must consider the metric

$$\langle \cdot, \cdot \rangle = \sum_{i=1}^n \frac{dx^i \otimes dx^i}{\left[1 - \frac{1}{4} \sum_i (x^i)^2\right]^2}$$

only on the open ball of radius 2,

$$B^n = B^n(2) = \{x \in \mathbb{R}^n : \sum_i (x^i)^2 < 4\},$$

but that $\langle \cdot, \cdot \rangle$ is already complete on B^n (see pg. II.339). Thus $(B^n, \langle \cdot, \cdot \rangle)$ must be isometric to the space $H^n \subset (\mathbb{R}^{n+1}, \langle \cdot, \cdot \rangle)$; a method for constructing an explicit isometry between $(B^n, \langle \cdot, \cdot \rangle)$ and H^n will be suggested later.

The model $(B^n, \langle \cdot, \cdot \rangle)$ will often be very useful, and we will examine it in great detail, determining, in particular, precisely what the isometries of $(B^n, \langle \cdot, \cdot \rangle)$ onto itself look like. In order to do this, however, we first need to generalize a few results from previous chapters.

First of all, Dupin's Theorem (4-10) on triply orthogonal systems of surfaces generalizes immediately to a theorem on n -orthogonal systems of hypersurfaces in \mathbb{R}^n . We will also need to generalize Theorem 2-2, concerning all-umbilic surfaces in \mathbb{R}^3 . For a hypersurface $M \subset \mathbb{R}^{n+1}$ we locally have a unit normal field $\nu: M \rightarrow S^n \subset \mathbb{R}^{n+1}$, and a map $d\nu: M_p \rightarrow M_p$ (Theorem 1-8); we call $p \in M$ an **umbilic** if $d\nu: M_p \rightarrow M_p$ is multiplication by a constant.

1. LEMMA. For $n \geq 2$, let $M \subset \mathbb{R}^{n+1}$ be a connected hypersurface with all points umbilics. Then M is part of a hyperplane or an n -dimensional sphere.

Remark: Later on we will have much more general results.

PROOF. As in the proof of Theorem 2-2, it suffices to prove this locally. Choose an adapted orthonormal moving frame $X_1, \dots, X_n, X_{n+1} = \nu$ on M . By hypothesis, there is a function λ on M such that

$$(1) \quad \nabla'_X X_{n+1} = -\lambda X \quad X \text{ tangent to } M.$$

In terms of the dual and connection forms we have

$$\psi_{n+1}^j(X) = \langle \nabla'_X X_{n+1}, X_j \rangle = -\lambda \langle X, X_j \rangle,$$

and thus

$$\psi_j^{n+1} = -\psi_{n+1}^j = \lambda \theta^j.$$

Taking the exterior derivative of this equation, we obtain

$$\begin{aligned} d\lambda \wedge \theta^j + \lambda d\theta^j &= d\psi_j^{n+1} = -\sum_i \psi_i^{n+1} \wedge \omega_j^i \quad (\text{pg. III.19}) \\ &= -\lambda \sum_i \theta^i \wedge \omega_j^i, \end{aligned}$$

while

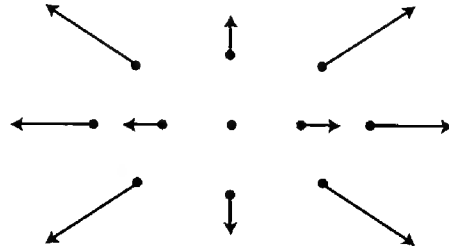

$$d\theta^j = -\sum_i \omega_j^i \wedge \theta^i.$$

So we find that

$$d\lambda \wedge \theta^j = 0 \quad j = 1, \dots, n.$$

This implies that $d\lambda = 0$, so λ is constant.

The remainder of the argument can be carried out as in the proof of Theorem 2-2, by considering an immersion $f: U \rightarrow M$ for $U \subset \mathbb{R}^n$ open. Here is an alternative (essentially equivalent) argument. If $\lambda = 0$, then all $\psi_j^{n+1} = 0$, so the second fundamental form $s = 0$; thus M is totally geodesic (Propositions 1-16 and 1-17), so M lies in a hyperplane. So we assume $\lambda \neq 0$. Let V be the vector field on \mathbb{R}^{n+1} defined by

$$V(p) = p_p \in \mathbb{R}^{n+1}_p.$$

If x^1, \dots, x^{n+1} is the standard coordinate system on \mathbb{R}^{n+1} , then

$$V = \sum_i x^i \frac{\partial}{\partial x^i},$$

and we easily see that $\nabla'_X V = X$ for all tangent vectors X of \mathbb{R}^{n+1} . Thus equation (1) can be written

$$\nabla'_X (X_{n+1} + \lambda V) = 0.$$

Thus the vector field $X_{n+1} + \lambda V$ is parallel along M . Identifying tangent vectors of \mathbb{R}^{n+1} with elements of \mathbb{R}^{n+1} , this means that $X_{n+1} + \lambda V$ is a constant vector v_0 on M , so we have

$$X_{n+1}(p) + \lambda p = v_0 \in \mathbb{R}^{n+1}.$$

Thus

$$p = \frac{v_0 - X_{n+1}(p)}{\lambda}$$

for all $p \in M$, which means that M lies in the sphere of radius $1/\lambda$ around the point v_0/λ . ♦

Using Lemma 1. and the generalization of Dupin's Theorem, it is now a straightforward matter to generalize Liouville's Theorem (4-12) to \mathbb{R}^n : every conformal map of an open subset of \mathbb{R}^n onto an open subset of \mathbb{R}^n is the restriction of a composition of similarities and inversions, in fact at most one of each. In addition (compare the proof of Lemma 4-13), these conformal maps take hyperplanes and spheres to hyperplanes and spheres.

With this information we are now in a good position to consider the isometries of $(B^n, \langle \cdot, \cdot \rangle)$. Since $\langle \cdot, \cdot \rangle$ is conformally equivalent to the usual metric $\sum_i dx^i \otimes dx^i$ on B^n , we see immediately that

- (1) Every isometry $f: (B^n, \langle \cdot, \cdot \rangle) \rightarrow (B^n, \langle \cdot, \cdot \rangle)$ onto itself is a conformal map of B^n onto itself (as a subset of \mathbb{R}^n with the usual metric).

We next claim

- (2) If $f: B^n \rightarrow B^n$ is a conformal map of B^n onto itself and $f_*: B^n_p \rightarrow B^n_p$ is a multiple of the identity for some $p \in B^n$, then f is the identity (or possibly minus the identity, if $p = 0$).

To prove this, consider the sphere $S = \text{boundary } B^n$. Then S is taken into itself by f (more precisely, by the composition of similarities and inversions of which f is the restriction). If P is a hyperplane through p , then $f(P)$ is a hyperplane or sphere tangent to P at p (since $f_*: B^n_p \rightarrow B^n_p$ is a multiple of the identity). But also the angle at which P cuts S must equal the angle at which $f(P)$ cuts $f(S) = S$. It follows easily that $f(P) = P$. Consequently, f cannot be an inversion or the composition of one inversion and one similarity, for the inversion must be through a point $p_* \notin B^n$, and then $f(P)$ could not be a plane. So f must be a similarity, and the desired result follows easily.

Now consider any conformal map $f: B^n \rightarrow B^n$ of B^n onto itself, and let $p \in B^n$ be a point $\neq 0$. If $X_1, \dots, X_n \in B^n_p$ is an orthonormal basis with respect to $\langle \cdot, \cdot \rangle_p$, then there is some $\lambda > 0$ with

$$\langle f_*(X_i), f_*(X_j) \rangle_{f(p)} = \lambda \cdot \delta_{ij},$$

so $\{f_*(X_i)/\sqrt{\lambda}\}$ is an orthonormal basis for $B^n_{f(p)}$. Consequently, there is an isometry $g: (B^n, \langle \cdot, \cdot \rangle) \rightarrow (B^n, \langle \cdot, \cdot \rangle)$ with

$$g_*(X_i) = \frac{1}{\sqrt{\lambda}} f_*(X_i).$$

Then $g^{-1} \circ f: B^n \rightarrow B^n$ is a conformal map of B^n onto itself (by (1)), and $(g^{-1} \circ f)_*: B^n_p \rightarrow B^n_p$ is a multiple of the identity. So $g = f$ by (2). Thus

- (3) Every conformal map $f: B^n \rightarrow B^n$ of B^n onto itself is an isometry of $(B^n, \langle \cdot, \cdot \rangle)$ onto itself.

We can now deduce some further information about $(B^n, \langle \cdot, \cdot \rangle)$. We know (pg. III.26) that the d -dimensional totally geodesic submanifolds through $0 \in B^n$ are just $B^n \cap P$, where P is a d -dimensional plane through 0 in \mathbb{R}^n . Now

any totally geodesic submanifold is the image of $B^n \cap P$ under some isometry $f: B^n \rightarrow B^n$. The map f is conformal by (1), so

- (4) Every totally geodesic submanifold of B^n is the intersection of B^n with a plane or sphere which intersects $S = \text{boundary } B^n$ orthogonally.

Conversely, suppose that Σ is a plane or sphere which intersects S orthogonally, and let $p \in \Sigma \cap B^n$. There is a totally geodesic submanifold of B^n tangent to Σ at p . By (4), this submanifold must intersect S orthogonally. So it must be precisely $\Sigma \cap B^n$. Thus

- (5) The intersection with B^n of a plane or sphere which intersects S orthogonally is a totally geodesic submanifold.

Next consider a geodesic sphere Σ around $0 \in B^n$ (that is, let Σ be the set of points at fixed $\langle \cdot, \cdot \rangle$ distance from 0). By symmetry of $\langle \cdot, \cdot \rangle$, the set Σ is an ordinary (hyper) sphere. Now any geodesic sphere is the image of Σ under some isometry $f: B^n \rightarrow B^n$. Since this isometry is a conformal map we see that

- (6) Every geodesic sphere of $(B^n, \langle \cdot, \cdot \rangle)$ is an ordinary hypersphere completely contained in B^n .

Now we will work on proving the converse of (6). Suppose we have an ordinary hypersphere Σ completely contained in B^n . We claim first of all that there is a hypersphere Σ' which is orthogonal to both Σ and S . To prove this

we note that by means of an inversion through a point of S , we can reduce the problem to that of finding a hypersphere Σ' orthogonal to a hyperplane H and a hypersphere Σ lying completely on one side of it. If Σ has center p and $q \in H$ is the point closest to p , then we simply choose Σ' to be a hypersphere around q whose radius has the length of a tangent from q to Σ . Now

that we have the hypersphere Σ' orthogonal to both Σ and S , we consider the intersection \bar{p} of Σ' and the line L between 0 and the center of Σ . Let

$f: B^n \rightarrow B^n$ be an isometry taking \bar{p} to 0. We know by (5) that $B^n \cap \Sigma'$ is a totally geodesic hypersurface. Therefore f must take Σ' to a hyperplane H through 0. Moreover, f takes the geodesic L to another geodesic through 0, i.e., to a straight line L' through 0, but not lying in H . The image hypersphere $f(\Sigma)$ must be perpendicular to both H and L' , which can happen only when $f(\Sigma)$ has center 0. So $f(\Sigma)$ is a geodesic sphere, which implies that Σ is also:

- (7) Every ordinary hypersphere completely contained in B^n is a geodesic sphere.

All of this information, by the way, was obtained only for the case $n \geq 3$, since we made use of Liouville's Theorem. The case $n = 2$ is sometimes analyzed by explicit computation, making use of the identification of \mathbb{R}^2 with \mathbb{C} (see Problems 4, 5, 6), but we can also use the information which we already have for $n \geq 3$. To do this we consider B^2 as a totally geodesic surface in B^3 . An isometry $f: B^2 \rightarrow B^2$ of B^2 onto itself clearly extends to an isometry $\tilde{f}: B^3 \rightarrow B^3$ of B^3 onto itself. Since \tilde{f} is conformal, f is also. Moreover, since \tilde{f} is a composition of at most one similarity and inversion, it is not hard to see that the same must be true of f (this information is not redundant in the 2-dimensional case). Conversely, if $f: B^2 \rightarrow B^2$ is a conformal map of B^2 onto itself which happens to be a composition of at most one similarity and inversion, then f can easily be extended to a similar conformal map $\tilde{f}: B^3 \rightarrow B^3$ of B^3 onto itself. Since \tilde{f} is an isometry, so is f . It now follows, exactly as before, that the geodesics of B^2 are portions of lines or circles intersecting S orthogonally, while the geodesic circles are the ordinary circles completely contained in B^2 .

In Addendum 2 to Chapter II.7 we also described a complete manifold of constant curvature $K_0 = -1$ by means of the metric

$$\sum_{i=1}^n \frac{dx^i \otimes dx^i}{(x^n)^2}$$

on the upper half-space $\mathcal{H}^n = \{a \in \mathbb{R}^n : a^n > 0\}$. It is easy to describe the isometry between \mathcal{H}^n and B^n . In fact, since the metric on each of them is conformally equivalent to the usual metric on \mathbb{R}^n , the isometry $f: B^n \rightarrow \mathcal{H}^n$ must be a conformal map. If we take an inversion I about a point $*$ on the boundary sphere S of B , then $I(B)$ will be an open half-space, and it is only necessary to compose I with an appropriate similarity. We now easily see that the isometries of \mathcal{H}^n onto itself are precisely the conformal maps taking \mathcal{H}^n onto itself; that the totally geodesic submanifolds of \mathcal{H}^n are $\Sigma \cap \mathcal{H}^n$ for planes and spheres Σ intersecting \mathbb{R}^{n-1} orthogonally; and that the geodesic spheres of \mathcal{H}^n are the ordinary spheres completely contained in \mathcal{H}^n . It will prove extremely useful to be able to shuttle back and forth between B^n and \mathcal{H}^n .

We have now given intrinsic characterizations of the sets $\Sigma \cap B^n$ [or $\Sigma \cap \mathcal{H}^n$] when Σ is a hyperplane or hypersphere intersecting S [or \mathbb{R}^{n-1}] either orthogonally, or else not at all. We also want to give intrinsic characterizations when Σ intersects non-orthogonally. There are two different cases to consider, the first of which is related to a certain limiting construction which played an essential role in the earliest investigations of non-Euclidean geometry. Take a ray L , with initial point p , in a non-Euclidean space. For each q on L , consider the sphere with center q that passes through p . As $q \rightarrow \infty$, this sphere approaches a surface. In the Euclidean case, this surface is just the

plane through p perpendicular to L ; in the non-Euclidean case, the limiting set is called a “limit sphere” or **horosphere**. It is easy to see that the horospheres of $(B^n, \langle \cdot, \cdot \rangle)$ are precisely $B^n \cap \Sigma$ where Σ is a hypersphere completely inside B except for one point. (First consider the horospheres determined by a ray starting at 0, as in the figure below, and then note that there are isometries of B^n

taking any horosphere to any other.) The early non-Euclidean geometers had their minds blown when they proved that the laws of *Euclidean* geometry hold on the horosphere; in other words, the horosphere is flat. The easiest way for us to see this is to consider an isometry $f: B^n \rightarrow \mathcal{H}^n$ which involves an inversion around the unique point $* \in \Sigma \cap S$. The image $f(\Sigma)$ is then a hyperplane parallel to \mathbb{R}^{n-1} . But the metric induced on this hyperplane is a constant multiple of $\sum_i dx^i \otimes dx^i$, so this hyperplane (which is a horosphere of \mathcal{H}^n) is flat; all other horospheres are isometric images of this one, so they are also flat.

To describe the other sets $\Sigma \cap B^n$ and $\Sigma \cap \mathcal{H}^n$, we first do a short computation in \mathcal{H}^2 . Consider a semi-circle intersecting \mathbb{R}^1 orthogonally, parameterized by

$$c(\theta) = (a + r \cos \theta, r \sin \theta).$$

This curve is a geodesic, apart from its parameterization. Its length from the point $c(\theta_0)$ to $c(\theta_1)$ is

$$\begin{aligned} \int_{\theta_0}^{\theta_1} |c'(\theta)| d\theta &= \int_{\theta_0}^{\theta_1} \left| (-r \sin \theta) \frac{\partial}{\partial x^1} + (r \cos \theta) \frac{\partial}{\partial x^2} \right| d\theta \\ &= \int_{\theta_0}^{\theta_1} \sqrt{\frac{(-r \sin \theta)^2 + (r \cos \theta)^2}{(r \cos \theta)^2}} d\theta \\ &= \int_{\theta_0}^{\theta_1} \frac{1}{\cos \theta} d\theta. \end{aligned}$$

Notice that this is independent of r . It follows that for a geodesic L which is a straight line perpendicular to \mathbb{R} , the set of points at a fixed distance d from L is a pair of straight lines making equal angles with L . Similarly, if P is a totally

geodesic hypersurface in \mathcal{H}^n consisting of a hyperplane to \mathbb{R}^{n-1} , then the set of points at a fixed distance d from P is a pair of hyperplanes P_1, P_2 making equal angles with P . For the isometry $f: B^n \rightarrow \mathcal{H}^n$, involving an inversion about the

point $* \in S$, the set $f^{-1}(P)$ is $\Sigma \cap B^n$ for some hyperplane or hypersphere Σ with $* \in \Sigma \cap S$; and the sets $f^{-1}(P_i)$ are sets of the same sort. We thus see that

three pairs of lines at fixed distances
from a given geodesic

a pair of surfaces at fixed distance from
a given totally geodesic surface

for hyperplanes or hyperspheres Σ which intersect S [or \mathbb{R}^{n-1}] in more than one point, but not orthogonally, the set $\Sigma \cap B^n$ [or $\Sigma \cap \mathcal{H}^n$] is one component of the set of points at a fixed distance from a totally geodesic hypersurface; these sets are thus called **equidistant hypersurfaces**.

By the way, we can also describe the geodesic spheres, horospheres, and equidistant hypersurfaces for

$$H^n = \{p \in \mathbb{R}^{n+1} : p^0 > 0 \text{ and } \langle p, p \rangle = -1\}.$$

They are all of the form $H^n \cap P$ for some hyperplane P . As illustrated in the figure on the top of the next page, the parabolas, which occur when P is parallel to generator of the cone $\sum_i (x^i)^2 = (x^0)^2$, are horospheres; ellipses, which occur when P makes a larger angle with the x^0 -axis, are geodesic spheres; and hyperbolas, which occur when P makes a smaller angle, are equidistant hypersurfaces. Although these assertions should look pictorially reasonable, we are not yet in a position to prove them (see page 78). For the moment we merely want to note that we would not obtain any new hypersurfaces by considering the sets $H^n \cap Q$ where Q is another quadric hypersurface of the form

$$Q = \{p \in \mathbb{R}^{n+1} : \langle p - p_0, p - p_0 \rangle = c\};$$

for it is easy to see that $H^n \cap Q$ is always of the form $H^n \cap P$ for some hyperplane P . (Analogously, the intersection of two ordinary spheres in \mathbb{R}^{n+1} is also the intersection of one sphere with a hyperplane.)

Much of the above discussion evolved from the existence of conformal maps from S^n or H^n to \mathbb{R}^n . Another kind of map will play an important role. A homeomorphism $\phi: M_1 \rightarrow M_2$ from M_1 into M_2 is called a **geodesic mapping** if for every geodesic γ of M_1 , the composition $\phi \circ \gamma$ is a reparameterization of a geodesic of M_2 . Notice that a geodesic mapping $\phi: M_1 \rightarrow M_2$ clearly also takes totally geodesic submanifolds of M_1 to totally geodesic submanifolds of M_2 .

As usual, we first consider S^n . We define the **central projection** ϕ of S^n to be the map which takes a point p in the open northern hemisphere S^{n+} of S^n to the intersection of $\mathbb{R}^n = \mathbb{R}^n \times \{1\} \subset \mathbb{R}^{n+1}$ with the straight line through p and the origin $0 \in \mathbb{R}^{n+1}$. It is clear that $\phi: S^{n+} \rightarrow \mathbb{R}^n$ is a geodesic mapping, since

the geodesics of S^n are intersections of S^n with planes through the center of S^n . An exactly analogous construction works for $H^n \subset (\mathbb{R}^n, \langle \cdot, \cdot \rangle)$, except now we

obtain a map defined on all of H^n . We define $\phi: H^n \rightarrow \mathbb{R}^n$ to be the map which

takes $p \in H^n$ to the intersection of $\mathbb{R}^n = \{(1, a^1, \dots, a^n) \in \mathbb{R}^{n+1}\}$ with the straight line through p and $0 \in \mathbb{R}^{n+1}$. In this case, the image of H^n is the open ball in \mathbb{R}^n bounded by the intersection of \mathbb{R}^n with the cone $\sum_i (x^i)^2 = (x^0)^2$; thus $\phi(H^n)$ is the open ball $B^n(1)$ of radius 1.

We can also construct a geodesic mapping by using the model $(B^n, \langle \cdot, \cdot \rangle) = (B^n(2), \langle \cdot, \cdot \rangle)$. To do this, we regard S^n as the unit sphere tangent to $\mathbb{R}^n = \mathbb{R}^n \times \{0\}$ at 0. Then the stereographic projection σ from the north pole of S^n

takes the open southern hemisphere of S^n diffeomorphically onto $B^n(2)$. A

geodesic γ in $(B^n, \langle \cdot, \cdot \rangle)$ is a straight line or circle intersecting $S = \text{boundary } B^n$ orthogonally. It follows from the properties of stereographic projection that $\sigma^{-1}(\gamma)$ is a semi-circle intersecting the equator of S^n orthogonally. Now let $g: S^n \rightarrow \mathbb{R}^n$ be the orthogonal projection $g(x^1, \dots, x^{n+1}) = (x^1, \dots, x^n)$. Then g takes circles intersecting the equator of S^n orthogonally onto straight line segments of \mathbb{R}^n . So $g \circ \sigma^{-1}: B^n(2) \rightarrow B^n(1)$ is a geodesic mapping. Using these geodesic mappings $H^n \rightarrow B^n(1)$ and $B^n(2) \rightarrow B^n(1)$, it is not hard (Problems 9, 10) to describe an isometry between H^n and $B^n(2)$.

Naturally, the geodesic mapping $S^{n+} \rightarrow \mathbb{R}^n$ and $H^n \rightarrow B^n(1)$, together with the standard coordinate system on \mathbb{R}^n , lead to new coordinate systems for S^{n+} and H^n . In particular, the unit ball $B^n(1)$, together with the metric induced by the metric on H^n , is called the “projective model” of H^n .

We could calculate the form of the metric in these coordinate systems, and describe the geodesic spheres, horospheres, and equidistant hypersurfaces of H^n in the projective model, but we will never need to know any of this information. For us, the only important result will be the *existence* of the geodesic maps $S^{n+} \rightarrow \mathbb{R}^n$ and $H^n \rightarrow B^n(1)$. This is not surprising in view of the following:

2. THEOREM (BELTRAMI). If M is a connected Riemannian n -manifold such that every point has a neighborhood that can be mapped geodesically to \mathbb{R}^n , then M has constant curvature.

PROOF. The case $n \geq 3$ follows immediately from Theorem I-18; it is the case $n = 2$ which causes all the trouble. Note first that in the case of a surface, Lemma II.7-18 implies that the curvature K satisfies

$$\begin{aligned}
 R_{hijk} &= K(g_{hj}g_{ik} - g_{hk}g_{ij}) \\
 &\Downarrow \\
 (1) \quad R^l_{ijk} &= \sum_{h=1}^2 g^{lh} R_{hijk} = K(\delta_j^l g_{ik} - \delta_k^l g_{ij}).
 \end{aligned}$$

We will use the mapping in the hypothesis of the theorem to identify our neighborhood in M with an open set in \mathbb{R}^2 , on which we use the standard coordinate system (x^1, x^2) . Thus the metric $\sum_{i,j} g_{ij} dx^i \otimes dx^j$ has the same geodesics as the metric $\sum_{i,j} \delta_{ij} dx^i \otimes dx^j$. Since the Christoffel symbols for the latter metric are all zero, Proposition II.6-18 shows that the Christoffel symbols for g_{ij} satisfy

$$\Gamma_{jk}^i = \delta_j^i \omega_k + \delta_k^i \omega_j$$

for certain functions ω_i . Hence we have

$$(2) \quad \Gamma_{11}^2 = \Gamma_{22}^1 = 0, \quad \Gamma_{11}^1 = 2\Gamma_{12}^2, \quad \Gamma_{22}^2 = 2\Gamma_{21}^1.$$

From equation (1), and the formula (**) for R^l_{ijk} on pg. II.188, we find that

$$(3a) \quad Kg_{11} = (\Gamma_{12}^2)^2 - \frac{\partial}{\partial x^1} \Gamma_{12}^2 \quad (3b) \quad Kg_{12} = \Gamma_{21}^1 \Gamma_{12}^2 - \frac{\partial}{\partial x^2} \Gamma_{12}^2$$

$$(3c) \quad Kg_{22} = (\Gamma_{12}^1)^2 - \frac{\partial}{\partial x^2} \Gamma_{12}^1 \quad (3d) \quad Kg_{21} = \Gamma_{12}^2 \Gamma_{12}^1 - \frac{\partial}{\partial x^1} \Gamma_{12}^1.$$

Notice that equations (3b) and (3d) imply that

$$(4) \quad \frac{\partial}{\partial x^2} \Gamma_{12}^2 = \frac{\partial}{\partial x^1} \Gamma_{12}^1.$$

We also have

$$\begin{aligned} 2g_{12}\Gamma_{12}^2 &= g_{12}\Gamma_{11}^1 && \text{by (2)} \\ &= g_{12}\Gamma_{11}^1 + g_{22}\Gamma_{11}^2 && \text{by (2)} \\ &= [11, 2] \\ &= \frac{1}{2} \left(\frac{\partial g_{12}}{\partial x^1} + \frac{\partial g_{12}}{\partial x^1} - \frac{\partial g_{11}}{\partial x^2} \right) \\ &= \frac{\partial g_{12}}{\partial x^1} - \frac{1}{2} \frac{\partial g_{11}}{\partial x^2}. \end{aligned}$$

Subtracting this equation from

$$g_{11}\Gamma_{12}^1 + g_{12}\Gamma_{12}^2 = [12, 1] = \frac{1}{2} \frac{\partial g_{11}}{\partial x^2},$$

we obtain

$$g_{11}\Gamma_{12}^1 - g_{12}\Gamma_{12}^2 = \frac{\partial g_{11}}{\partial x^2} - \frac{\partial g_{12}}{\partial x^1}.$$

Multiplying by K , and using (3a) and (3b), we obtain

$$(5) \quad K \left(\frac{\partial g_{11}}{\partial x^2} - \frac{\partial g_{12}}{\partial x^1} \right) = \Gamma_{12}^2 \frac{\partial}{\partial x^2} \Gamma_{12}^2 - \Gamma_{12}^1 \frac{\partial}{\partial x^1} \Gamma_{12}^2.$$

Now differentiate (3a) with respect to x^2 , and subtract the result of differentiating (3b) with respect to x^1 . We obtain

$$\begin{aligned} g_{11} \frac{\partial K}{\partial x^2} - g_{12} \frac{\partial K}{\partial x^1} + K \left(\frac{\partial g_{11}}{\partial x^2} - \frac{\partial g_{12}}{\partial x^1} \right) \\ = 2\Gamma_{12}^2 \frac{\partial}{\partial x^2} \Gamma_{12}^2 - \Gamma_{21}^1 \frac{\partial}{\partial x^1} \Gamma_{12}^2 - \Gamma_{12}^2 \frac{\partial}{\partial x^1} \Gamma_{21}^1. \end{aligned}$$

Using (5) we have

$$g_{11} \frac{\partial K}{\partial x^2} - g_{12} \frac{\partial K}{\partial x^1} = \Gamma_{12}^2 \frac{\partial}{\partial x^2} \Gamma_{12}^2 - \Gamma_{12}^2 \frac{\partial}{\partial x^1} \Gamma_{21}^1.$$

Hence by (4) we have

$$g_{11} \frac{\partial K}{\partial x^2} - g_{12} \frac{\partial K}{\partial x^1} = 0.$$

Similarly,

$$-g_{12} \frac{\partial K}{\partial x^2} - g_{22} \frac{\partial K}{\partial x^1} = 0.$$

Since the determinant $g_{11}g_{22} - (g_{12})^2 \neq 0$, this implies that $\partial K/\partial x^1 = 0$ and $\partial K/\partial x^2 = 0$. ♦

B. CURVES IN A RIEMANNIAN MANIFOLD

Before investigating general submanifolds of a Riemannian manifold, we will consider the special case of 1-dimensional submanifolds, which works out quite differently than all other cases. Our aim is not to obtain any particularly startling theorems about curves in Riemannian manifolds, but merely to show briefly how the Serret-Frenet formulas of Chapter II.1 generalize; along the way we will derive a few results which are needed to discuss higher dimensions.

Consider a Riemannian manifold $(N, \langle \cdot, \cdot \rangle)$, and an arclength parameterized curve $c: [a, b] \rightarrow N$. We use N for the ambient manifold to conform with the notation to be used in the general case of a submanifold $M \subset N$. For consistency of notation, we also use ∇' for the covariant derivative in N , even though there will be no occasion to consider the covariant derivative ∇ in the 1-dimensional manifold $c([a, b])$. We will let $\mathbf{v}_1 = c'$ denote the unit tangent vector of c . Since $\langle \mathbf{v}_1, \mathbf{v}_1 \rangle = 1$ we have

$$0 = \frac{d}{ds} \langle \mathbf{v}_1(s), \mathbf{v}_1(s) \rangle = 2 \left\langle \mathbf{v}_1(s), \frac{D' \mathbf{v}_1(s)}{ds} \right\rangle.$$

We define the first “curvature function” κ_1 of c by

$$\kappa_1(s) = \left| \frac{D' \mathbf{v}_1(s)}{ds} \right|,$$

and if $\kappa_1(s) \neq 0$ for all s we set

$$\mathbf{v}_2(s) = \kappa_1(s)^{-1} \cdot \frac{D' \mathbf{v}_1(s)}{ds},$$

so that \mathbf{v}_2 is a unit vector field along c which is everywhere perpendicular to \mathbf{v}_1 . We then have the “Frenet formula”

$$(F_1) \quad \frac{D'\mathbf{v}_1(s)}{ds} = \kappa_1(s)\mathbf{v}_2(s).$$

Now

$$\langle \mathbf{v}_2, \mathbf{v}_2 \rangle = 1 \implies \left\langle \mathbf{v}_2(s), \frac{D'\mathbf{v}_2(s)}{ds} \right\rangle = 0.$$

Moreover,

$$\begin{aligned} \langle \mathbf{v}_1, \mathbf{v}_2 \rangle = 0 &\implies 0 = \left\langle \frac{D'\mathbf{v}_1(s)}{ds}, \mathbf{v}_2(s) \right\rangle + \left\langle \mathbf{v}_1(s), \frac{D'\mathbf{v}_2(s)}{ds} \right\rangle \\ &= \kappa_1(s) + \left\langle \mathbf{v}_1(s), \frac{D'\mathbf{v}_2(s)}{ds} \right\rangle \quad \text{by (F}_1\text{)}. \end{aligned}$$

This implies that

$$\frac{D'\mathbf{v}_2(s)}{ds} = -\kappa_1(s)\mathbf{v}_1(s) + \text{vector perpendicular to } \mathbf{v}_1(s) \text{ and } \mathbf{v}_2(s).$$

We define the second “curvature function” κ_2 by

$$\kappa_2(s) = \left| \frac{D'\mathbf{v}_2(s)}{ds} + \kappa_1(s)\mathbf{v}_1(s) \right|,$$

and if $\kappa_2(s) \neq 0$ for all s , we set

$$\mathbf{v}_3(s) = \kappa_2(s)^{-1} \left[\frac{D'\mathbf{v}_2(s)}{ds} + \kappa_1(s)\mathbf{v}_1(s) \right],$$

so that \mathbf{v}_3 is a unit vector field along c which is everywhere perpendicular to \mathbf{v}_1 and \mathbf{v}_2 . We then have

$$(F_2) \quad \frac{D'\mathbf{v}_2(s)}{ds} = -\kappa_1(s)\mathbf{v}_1(s) + \kappa_2(s)\mathbf{v}_3(s).$$

Now suppose, inductively, that for $j \leq m = \dim N$ we have orthonormal vector fields $\mathbf{v}_1, \dots, \mathbf{v}_j$ along c and nowhere zero curvature functions $\kappa_1, \dots, \kappa_{j-1}$ such that

$$(F_1) \quad \frac{D'\mathbf{v}_1(s)}{ds} = \kappa_1(s)\mathbf{v}_2(s)$$

$$(F_2) \quad \frac{D'\mathbf{v}_2(s)}{ds} = -\kappa_1(s)\mathbf{v}_1(s) + \kappa_2(s)\mathbf{v}_3(s)$$

\vdots

$$(F_{j-1}) \quad \frac{D'\mathbf{v}_{j-1}(s)}{ds} = -\kappa_{j-2}(s)\mathbf{v}_{j-2}(s) + \kappa_{j-1}(s)\mathbf{v}_j(s).$$

Then

$$\langle \mathbf{v}_j, \mathbf{v}_j \rangle = 1 \implies \left\langle \frac{D'\mathbf{v}_j(s)}{ds}, \mathbf{v}_j(s) \right\rangle = 0,$$

while for $i < j$ we have

$$\begin{aligned} \langle \mathbf{v}_j, \mathbf{v}_i \rangle = 0 &\implies \left\langle \mathbf{v}_i(s), \frac{D'\mathbf{v}_j(s)}{ds} \right\rangle = - \left\langle \frac{D'\mathbf{v}_i(s)}{ds}, \mathbf{v}_j \right\rangle \\ &= \begin{cases} 0 & i \neq j-1 \\ -\kappa_{j-1}(s) & i = j-1. \end{cases} \end{aligned}$$

Hence

$$\begin{aligned} (*) \quad \frac{D'\mathbf{v}_j(s)}{ds} &= -\kappa_{j-1}(s)\mathbf{v}_{j-1}(s) \\ &\quad + \text{vector perpendicular to } \mathbf{v}_1(s), \dots, \mathbf{v}_j(s). \end{aligned}$$

If $j < m$ we set

$$\kappa_j(s) = \left| \frac{D'\mathbf{v}_j(s)}{ds} + \kappa_{j-1}(s)\mathbf{v}_{j-1}(s) \right|,$$

and if $\kappa_j(s) \neq 0$ for all s we set

$$\mathbf{v}_{j+1}(s) = \kappa_j(s)^{-1} \cdot \left[\frac{D'\mathbf{v}_j(s)}{ds} + \kappa_{j-1}(s)\mathbf{v}_{j-1}(s) \right].$$

We then have

$$(F_j) \quad \frac{D'\mathbf{v}_j(s)}{ds} = -\kappa_{j-1}(s)\mathbf{v}_{j-1}(s) + \kappa_j(s)\mathbf{v}_{j+1}(s).$$

If $j = m$, then only the zero vector is perpendicular to $\mathbf{v}_1(s), \dots, \mathbf{v}_m(s)$, so equation (*) becomes

$$(F_m) \quad \frac{D'\mathbf{v}_m(s)}{ds} = -\kappa_{m-1}(s)\mathbf{v}_{m-1}(s).$$

It is easy to see that we have equations (F₁) to (F_{j-1}) with nowhere zero functions $\kappa_1, \dots, \kappa_{j-1}$ if and only if

$$c'(s), \quad \frac{D'c'(s)}{ds}, \quad \dots, \quad \frac{D'^{(j-1)}c'(s)}{ds^{j-1}}$$

are everywhere linearly independent; the vector fields $\mathbf{v}_1, \dots, \mathbf{v}_j$ along c are then precisely the result of applying the Gram-Schmidt orthonormalization

process to these vectors. If $D'^{(j)}c'(s)/ds^j$ is everywhere linearly dependent on $c'(s), \dots, D'^{(j-1)}c'(s)/ds^{j-1}$, then the function κ_j will be everywhere 0, and we cannot define \mathbf{v}_{j+1} , but we can write instead

$$(F'_j) \quad \frac{D'\mathbf{v}_j(s)}{ds} = -\kappa_{j-1}(s)\mathbf{v}_{j-1}(s).$$

[Note, in particular, that (F'_m) is just (F_m) .] As in the theory of curves in \mathbb{R}^3 , we consider only intervals where a set of equations $(F_1), \dots, (F_{j-1}), (F'_j)$ holds for some $j \leq m$. In other words, we assume that $\kappa_1, \dots, \kappa_{j-1}$ are nowhere zero, while κ_j is identically zero. We call $\mathbf{v}_1, \dots, \mathbf{v}_j$ the “Frenet frame” for c . The subspace of $N_{c(s)}$ spanned by $\mathbf{v}_1(s)$ and $\mathbf{v}_i(s)$ is sometimes called the $(i-1)^{\text{st}}$ **osculating plane** of c at s .

Notice that once we have $c'(s), \dots, D'^{(m-2)}c'(s)/ds^{m-2}$ linearly independent, so that $\mathbf{v}_1, \dots, \mathbf{v}_{m-1}$ are defined, then there are only two possible choices for each $\mathbf{v}_m(s)$. Having made a choice of $\mathbf{v}_m(a)$, there is then a unique continuous way of choosing $\mathbf{v}_m(s)$ for all $s \in [a, b]$. We still have equations (F_1) to (F_m) , but now the function κ_{m-1} might take on negative values, whereas all other κ_j , being non-zero norms, are everywhere positive. The particularly interesting situation occurs when N is oriented. Then we define $\mathbf{v}_m(s)$ to be the unique unit vector in $N_{c(s)}$ orthogonal to $\mathbf{v}_1(s), \dots, \mathbf{v}_{m-1}(s)$ such that $(\mathbf{v}_1(s), \dots, \mathbf{v}_m(s))$ is positively oriented [equivalently, we can define $\mathbf{v}_m(s) = \mathbf{v}_1(s) \times \dots \times \mathbf{v}_{m-1}(s)$, where the cross-product is determined by the metric and the orientation (see Problem 11)]. For curves in \mathbb{R}^3 this is precisely how we defined the binormal $\mathbf{b} = \mathbf{v}_3$, and obtained the torsion $\tau = \kappa_2$ which could be positive, negative, or zero. When we apply this procedure to arclength parameterized curves c in an oriented 2-dimensional Riemannian manifold, we obtain an everywhere defined curvature κ_1 , whose values may be positive, negative, or zero. Clearly, κ_1 is just the geodesic curvature κ_g defined previously.

In the next theorem we will, for simplicity, ignore these refinements and consider only curves with $c'(s), \dots, D'^{(m-1)}c'(s)/ds^{m-1}$ everywhere linearly independent. Readers may sort out for themselves the details which have to be changed when N is oriented and we allow κ_{m-1} to take on non-positive values.

3. THEOREM. (I) Let $c, \bar{c}: [a, b] \rightarrow N^m$ be arclength parameterized curves with nowhere zero curvature functions $\kappa_1, \dots, \kappa_{m-1}$ and $\bar{\kappa}_1, \dots, \bar{\kappa}_{m-1}$, respectively; and Frenet frames $\mathbf{v}_1, \dots, \mathbf{v}_m$ and $\bar{\mathbf{v}}_1, \dots, \bar{\mathbf{v}}_m$, respectively. Suppose that $\kappa_i = \bar{\kappa}_i$ for $1 \leq i \leq m-1$, and that

$$c(a) = \bar{c}(a) \quad \text{and} \quad \mathbf{v}_i(a) = \bar{\mathbf{v}}_i(a) \quad \text{for } i = 1, \dots, m.$$

Then $c = \bar{c}$.

(2) Let N^m be complete, let $\kappa_1, \dots, \kappa_{m-1}: [a, b] \rightarrow \mathbb{R}$ be everywhere positive continuous functions, and let $\hat{\mathbf{v}}_1, \dots, \hat{\mathbf{v}}_m$ be an orthonormal basis for some N_p . Then there is an arclength parameterized curve $c: [a, b] \rightarrow N$ with $c(a) = p$ whose curvature functions are $\kappa_1, \dots, \kappa_{m-1}$ and whose Frenet frame $\mathbf{v}_1, \dots, \mathbf{v}_m$ satisfies $\mathbf{v}_i(a) = \hat{\mathbf{v}}_i$ for $1 \leq i \leq m$.

PROOF. To prove (1) it clearly suffices (by a least upper bound argument) to show that $c(s) = \bar{c}(s)$ for s sufficiently close to a . So we might as well assume that $M = \mathbb{R}^m$, with some metric $\sum_{i,j} g_{ij} dx^i \otimes dx^j$, where x^1, \dots, x^m is the standard coordinate system for \mathbb{R}^m . Let $v_i(s) \in \mathbb{R}^m$ be the vector representing $\mathbf{v}_i(s)$ when we identify tangent vectors of \mathbb{R}^m with elements of \mathbb{R}^m in the usual way. We thus have $m+1$ functions

$$c, v_1, \dots, v_m: [a, b] \rightarrow \mathbb{R}^m.$$

We will also let $Dv_i(s)/ds$ be the vector representing $D\mathbf{v}_i(s)/ds$ when we identify tangent vectors of \mathbb{R}^m with elements of \mathbb{R}^m . The formula on pg. II.232 shows that $Dv_j(s)/ds$ can be written in terms of

$$c(s), c'(s), v_j(s), v_j'(s), \quad \text{i.e.,} \quad c(s), v_1(s), v_j(s), v_j'(s).$$

Each Frenet equation (F_j) then gives us an equation

$$(E_j) \quad v_j'(s) = F_j(c(s), v_1(s), \dots, v_m(s)).$$

We also have the equation

$$(E_0) \quad c'(s) = v_1(s).$$

So the equations $(E_0), (E_1), \dots, (E_m)$ gives us an equation

$$(*) \quad \alpha'(s) = F(\alpha(s))$$

for the function $\alpha = (c, v_1, \dots, v_m)$. The function F depends only on $\kappa_1, \dots, \kappa_{m-1}$ (and the Christoffel symbols).

For the function $\bar{\alpha} = (\bar{c}, \bar{v}_1, \dots, \bar{v}_m)$ there is a similar equation

$$\bar{\alpha}'(s) = \bar{F}(\bar{\alpha}(s)).$$

Moreover, since $\bar{\kappa}_i = \kappa_i$ for all i , the function \bar{F} is exactly the same as F . Now by hypothesis, the functions α and $\bar{\alpha}$ are equal at a , so by uniqueness of solutions of $(*)$ we have $\alpha = \bar{\alpha}$. Hence $c = \bar{c}$.

To prove (2) we first show that the desired curve c can be defined on some interval $[a, a + \varepsilon]$. Again we may clearly assume that $M = \mathbb{R}^m$. Now we can solve equation (*) on some interval $[a, a + \varepsilon]$, with any given initial conditions. This gives us a curve $c: [a, a + \varepsilon] \rightarrow M$ and vector fields $c' = \mathbf{v}_1, \dots, \mathbf{v}_m$ along c satisfying the Frenet formulas (F_1) to (F_m) , with

$$c(a) = p \quad \text{and} \quad \mathbf{v}_i(a) = \mathring{\mathbf{v}}_i, \quad 1 \leq i \leq m.$$

We have

$$\langle \mathbf{v}_i, \mathbf{v}_j \rangle'(s) = \left\langle \frac{D\mathbf{v}_i(s)}{ds}, \mathbf{v}_j(s) \right\rangle + \left\langle \mathbf{v}_i(s), \frac{D\mathbf{v}_j(s)}{ds} \right\rangle;$$

using the formulas (F_1) to (F_m) , we find that this is zero. Since $\{\mathbf{v}_i(a)\} = \{\mathring{\mathbf{v}}_i\}$ is orthonormal, $\{\mathbf{v}_i\}$ must therefore be orthonormal everywhere. So $\mathbf{v}_1, \dots, \mathbf{v}_m$ is the Frenet frame of c , and the κ_i are its curvatures.

In order to extend c to all of $[a, b]$, we first consider the equation (*) once again. If we choose our initial point p to lie in some compact set, then there will be $\varepsilon > 0$ with the property that for any orthonormal $\{\mathring{\mathbf{v}}_i\}$ at any such p , there is a curve $c: [a, a + \varepsilon] \rightarrow N$ with curvature functions κ_i on $[a, a + \varepsilon]$, whose Frenet frame $\mathbf{v}_1, \dots, \mathbf{v}_m$ satisfies $\mathbf{v}_i(a) = \mathring{\mathbf{v}}_i$. The size of ε will depend on bounds for F , and hence only on bounds for the κ_i , as well as bounds for the Christoffel symbols Γ_{ij}^k . It is thus clear that for every point $q \in M$ there is $\delta(q) > 0$ with the following property:

- (**) If $d(p, q) < \delta(q)$ and $\{\mathring{\mathbf{v}}_i\}$ is an orthonormal basis for M_p , then for any a' with $a < a' < b$ there is a curve $c: [a', \min(a' + \delta(q), b)] \rightarrow M$ with curvature functions κ_i on this interval, whose Frenet frame $\mathbf{v}_1, \dots, \mathbf{v}_m$ satisfies $\mathbf{v}_i(a') = \mathring{\mathbf{v}}_i$.

Now by a least upper bound argument it clearly suffices to show that the curve $c: [a, a + \varepsilon] \rightarrow M$, with Frenet frame $\mathbf{v}_1, \dots, \mathbf{v}_m$, can always be extended to the closed interval $[a, a + \varepsilon]$. The curve c is parameterized by arclength (since $\mathbf{v}_1 = c'$ has length 1), so for all $a < a' < a + \varepsilon$ we have $d(c(a), c(a')) \leq \text{length of } c \text{ on } [a, a'] = a' - a < \varepsilon$. So the image of c on $[a, a + \varepsilon]$ lies in some compact subset K of the complete manifold M . Thus there is $\delta > 0$ which will serve as $\delta(q)$ in (**) for all $q \in K$. Now choose $a < a' < a + \varepsilon$, so that $(a + \varepsilon) - a' < \delta$, and find the curve \bar{c} with curvature functions κ_i , whose Frenet frame $\bar{\mathbf{v}}_1, \dots, \bar{\mathbf{v}}_m$ satisfies $\bar{\mathbf{v}}_i(a') = \mathbf{v}_i(a')$. The curve \bar{c} is defined at least on $[a', \varepsilon]$ by (**), and c followed by \bar{c} is an extension of c at least as far as $c + \varepsilon$. ♦

4. COROLLARY. Let N be a complete m -dimensional Riemannian manifold of constant curvature K_0 . Let $c, \bar{c}: [a, b] \rightarrow N$ be arclength parameterized curves with nowhere zero curvature functions $\kappa_1, \dots, \kappa_{m-1}$ and $\bar{\kappa}_1, \dots, \bar{\kappa}_{m-1}$, respectively. If $\kappa_i = \bar{\kappa}_i$ for $1 \leq i \leq m-1$, then there is a unique isometry $A: N \rightarrow N$ such that $\bar{c} = A \circ c$.

PROOF. Left to the reader. ♦

We also want to consider curves with $\kappa_1, \dots, \kappa_{j-1}$ nowhere zero, but κ_j identically zero, for some $j \leq m-1$. In Chapter II.1 we found that curves with $\kappa = 0$ are straight lines, while curves with $\tau = 0$ lie in a plane. The generalization for curves in \mathbb{R}^m is the following.

5. THEOREM. Let $c: [a, b] \rightarrow \mathbb{R}^m$ be an arclength parameterized curve with $\kappa_1, \dots, \kappa_{j-1}$ nowhere zero, and κ_j everywhere zero. Then c lies in some j -dimensional plane in \mathbb{R}^m .

PROOF. Let $\mathbf{v}_1, \dots, \mathbf{v}_j$ be the Frenet frame for c , and let $\Delta(s) \subset \mathbb{R}^m_{c(s)}$ be the j -dimensional subspace of $\mathbb{R}^m_{c(s)}$ spanned by $\mathbf{v}_1(s), \dots, \mathbf{v}_j(s)$. We claim that all $\Delta(s)$ are parallel (considered as j -dimensional planes in \mathbb{R}^m). To prove this, we note that since $D'\mathbf{v}_i(s)/ds$ is just $\mathbf{v}_i'(s)$ in \mathbb{R}^m , the Frenet equations $(F_1), \dots, (F_{j-1}), (F'_j)$ show that each $\mathbf{v}_i'(s)$ is a linear combination of certain of the $\mathbf{v}_i(s)$,

$$\mathbf{v}_i'(s) = \sum_{t=1}^j a_{it}(s) \mathbf{v}_t(s).$$

So if \mathbf{w} is a parallel vector field on \mathbb{R}^m (that is, if for some $w \in \mathbb{R}^m$ we have $\mathbf{w}(p) = w_p$ for all p), then

$$(*) \quad \frac{d}{ds} \langle \mathbf{v}_i(s), \mathbf{w}(c(s)) \rangle = \langle \mathbf{v}_i'(s), \mathbf{w}(c(s)) \rangle = \sum_{t=1}^j a_{it}(s) \langle \mathbf{v}_t(s), \mathbf{w}(c(s)) \rangle.$$

By uniqueness of solutions of the system $(*)$, we see that if all $\langle \mathbf{v}_i(a), \mathbf{w}(c(a)) \rangle = 0$, then all $\langle \mathbf{v}_i(s), \mathbf{w}(c(s)) \rangle = 0$ for all s . In other words, $\Delta(s)$ is always orthogonal to the same vectors as $\Delta(a)$. Hence $\Delta(s)$ is parallel to $\Delta(a)$. Our result now follows from

6. LEMMA. Let $c: [a, b] \rightarrow \mathbb{R}^m$ be an immersed curve, and for each s let $\Delta(s) \subset \mathbb{R}^m_{c(s)}$ be a j -dimensional subspace of $\mathbb{R}^m_{c(s)}$ with $c'(s) \in \Delta(s)$. Suppose that all $\Delta(s)$ are parallel. Then c is a curve in some j -dimensional plane $P \subset \mathbb{R}^m$, and P is just $\exp(\Delta(s))$ for any s .

PROOF. Let $P = \Delta(a)$, considered as a j -dimensional plane in \mathbb{R}^m . Without loss of generality we may assume that P is parallel to the (x^1, \dots, x^j) -plane. If c does not lie entirely in P , then by the mean value theorem some tangent vector $c'(s)$ has a non-zero k^{th} component for some $k > j$. But this is impossible,

since $c'(s) \in \Delta(s)$ and $\Delta(s)$ is parallel to $P = \Delta(a)$. So c lies in P . Since each $\Delta(s)$ is parallel to $P = \Delta(a)$ and also contains the point $c(s) \in P$, each $\Delta(s)$ must equal P when $\Delta(s)$ is considered as a j -dimensional plane in \mathbb{R}^m . In other words, $P = \exp(\Delta(s))$. ♦

As soon as we try to replace \mathbb{R}^m in Theorem 5 with a manifold N of constant curvature, we find that the proof of Lemma 6 doesn't generalize at all. However, the result is still true, and we will give two proofs, exploiting two different descriptions of constant curvature manifolds. First consider a curve $c: [a, b] \rightarrow N$ in any Riemannian manifold N , and suppose that for each s we have a j -dimensional subspace $\Delta(s) \subset N_{c(s)}$, so that Δ is a “distribution along c ”. Let $\tau_s: N_{c(a)} \rightarrow N_{c(s)}$ be the parallel translation along c from $c(a)$ to $c(s)$. We say that Δ is **parallel along c** if $\tau_s(\Delta(a)) = \Delta(s)$ for all s . Suppose that Δ is parallel along c and that V is a smooth vector field along c belonging to Δ (that is, $V(s) \in \Delta(s)$ for all s). Proposition II.6-3 immediately shows that

$$\frac{D'V(s)}{ds} \in \Delta(s) \quad \text{for all } s,$$

so that $D'V(s)/ds$ also belongs to Δ . We need the converse assertion also.

7. PRE-LEMMA. Let $c: [a, b] \rightarrow N$ be a curve in a Riemannian manifold N , and let Δ be a smooth j -dimensional distribution along c . Suppose that $D'V(s)/ds$ belongs to Δ whenever V is a smooth vector field belonging to Δ . Then Δ is parallel along c .

PROOF. Choose everywhere linearly independent smooth vector fields V_1, \dots, V_j along c belonging to Δ . By hypothesis, we can write

$$(1) \quad \frac{D' V_i(s)}{ds} = \sum_{t=1}^j a_{it}(s) V_t(s)$$

for certain smooth functions a_{it} . We claim that there are functions $b_{\lambda i}$, with arbitrary initial conditions $b_{\lambda i}(a)$, such that

$$(2) \quad \frac{D'}{ds} \sum_{\lambda=1}^j b_{\lambda i}(s) V_\lambda(s) = 0, \quad i = 1, \dots, j.$$

In fact, equation (2) is equivalent to

$$\begin{aligned} 0 &= \sum_{\lambda=1}^j b_{\lambda i}'(s) V_\lambda(s) + \sum_{\lambda=1}^j b_{\lambda i}(s) \frac{D' V_\lambda(s)}{ds} \\ &= \sum_{t=1}^j b_{it}'(s) V_t(s) + \sum_{\lambda, t=1}^j b_{\lambda i}(s) a_{t\lambda}(s) V_t(s) \quad \text{by (1),} \end{aligned}$$

and hence to

$$(3) \quad b_{it}'(s) = \sum_{\lambda=1}^j a_{t\lambda}(s) b_{\lambda i}(s), \quad i = 1, \dots, j.$$

Since (3) is a linear equation, we can solve it on the whole interval $[a, b]$, with arbitrary initial conditions. Choose the initial conditions $b_{\lambda i}(a) = \delta_{\lambda i}$, and set

$$W_i(s) = \sum_{\lambda=1}^j b_{\lambda i}(s) V_\lambda(s).$$

Then the vector fields W_i along c are parallel, by (2), and linearly independent at a , hence linearly independent everywhere. So the $W_i(s)$ span $\Delta(s)$ for all s , which shows that Δ is parallel along c . ♦

8. LEMMA. Let N be a manifold of constant curvature K_0 . Let $c: [a, b] \rightarrow N$ be an immersed curve, and let Δ be a j -dimensional distribution along c such that $c'(s) \in \Delta(s)$ for all s . Suppose that Δ is parallel along c . Then c lies in some j -dimensional totally geodesic submanifold $P \subset N$, and $\exp(\Delta(s)) \subset P$ for all s .

FIRST PROOF. It is easy to see that this result is essentially a local one, so without loss of generality we take N to be the complete simply-connected manifold of constant curvature K_0 . Consider first the case $K_0 > 0$, so that $N = S^m(K_0) \subset \mathbb{R}^{m+1}$. We can then consider $V(s) \subset \mathbb{R}^{m+1}_{c(s)}$. We denote the covariant derivatives in N and \mathbb{R}^{m+1} by ∇' and ∇ , respectively, and we will let \mathbf{v} be a unit normal field on $N = S^m(K_0)$.

Let V be a vector field along c which belongs to Δ , so that $D'V/ds$ also belongs to Δ , since Δ is parallel along c . If \mathbf{D}'/ds denotes the covariant derivative along c in \mathbb{R}^{n+1} , then Corollary 1-2 gives

$$\mathbf{T} \left(\frac{\mathbf{D}'V(s)}{ds} \right) = \frac{D'V(s)}{ds} \in \Delta(s).$$

Thus we see that

$$(1) \quad V(s) \in \Delta(s) \text{ for all } s \implies \frac{\mathbf{D}'V(s)}{ds} \in \Delta(s) + \mathbb{R} \cdot \mathbf{v}(c(s)) \text{ for all } s.$$

On the other hand, we also have

$$(2) \quad \begin{aligned} \frac{\mathbf{D}'\mathbf{v}(c(s))}{ds} &= \nabla'_{c'(s)}\mathbf{v} = (\text{constant}) \cdot c'(s), \\ &\text{since all points of } N \text{ are umbilics} \\ &\in \Delta(s), \quad \text{by assumption on } \Delta. \end{aligned}$$

Now let

$$\mathbf{\Delta}(s) = \Delta(s) \oplus \mathbb{R} \cdot \mathbf{v}(c(s)) \in \mathbb{R}^{m+1}_{c(s)}.$$

From (1) and (2) we see that for a vector field W along c in \mathbb{R}^{m+1} we have

$$W(s) \in \mathbf{\Delta}(s) \text{ for all } s \implies \frac{\mathbf{D}'W(s)}{ds} \in \mathbf{\Delta}(s) \text{ for all } s.$$

By our prelemmanary remark we see that $\mathbf{\Delta}$ is parallel along c in \mathbb{R}^{m+1} . So Lemma 6 shows that c lies in some $(j+1)$ -dimensional plane $P \subset \mathbb{R}^{m+1}$, and $P = \exp(\mathbf{\Delta}(s))$ for all s . Since $\mathbf{v}(c(s)) \in \mathbf{\Delta}(s)$, the plane P must pass through the origin $0 \in \mathbb{R}^{n+1}$. Hence c is contained in $P \cap S^m(K_0)$, which is a j -dimensional totally geodesic subspace of $S^m(K_0)$. Clearly, we also have $\exp(\Delta(s)) \subset P \cap S^m(K_0)$ for all s .

The case $K_0 < 0$ can be proved similarly, taking N to be $H^m(K_0)$, considered as a subset of \mathbb{R}^{m+1} with the Lorentzian metric.

SECOND PROOF. As the result is essentially local, we can assume that we have a geodesic mapping $\phi: N \rightarrow \mathbb{R}^m$. If $\bar{\nabla}$ denotes covariant differentiation on \mathbb{R}^m , then Proposition II.6-18 shows that there is a 1-form ω on \mathbb{R}^m with

$$(1) \quad \bar{\nabla}_{\phi_* X} \phi_* Y - \phi_*(\nabla'_X Y) = \omega(\phi_* X) \cdot \phi_* Y + \omega(\phi_* Y) \cdot \phi_* X.$$

Let

$$\gamma(s) = \phi(c(s))$$

$$\bar{\Delta}(s) = \phi_* \Delta(s) \subset \mathbb{R}^m_{\gamma(s)}.$$

Then we have

$$(2) \quad \gamma'(s) = \phi_* c'(s) \in \phi_* \Delta(s) = \bar{\Delta}(s).$$

If V is a vector field along c with $V(s) \in \Delta(s)$ for all s , and hence $D'V(s)/ds \in \Delta(s)$ for all s , the equation (1) implies that

$$\begin{aligned} \frac{\bar{D}\phi_* V(s)}{ds} &= \phi_* \left(\frac{D'V(s)}{ds} \right) + \omega(\gamma'(s)) \cdot \phi_* V(s) + \omega(\phi_* V(s)) \cdot \gamma'(s) \\ &\in \bar{\Delta}(s), \quad \text{by (2).} \end{aligned}$$

In other words, if W is a vector field along γ with $W(s) \in \bar{\Delta}(s)$ for all s , then also $\bar{D}W(s)/ds \in \bar{\Delta}(s)$ for all s . Once again, this implies that $\bar{\Delta}$ is parallel along γ . So Lemma 6 implies that γ lies in some j -dimensional plane $P \subset \mathbb{R}^m$. Then c lies in $\phi^{-1}(P)$, which is totally geodesic j -dimensional submanifold of N . Clearly, we also have $\exp(\Delta(s)) \subset \phi^{-1}(P)$ for all s . ♦

9. THEOREM. Let N be a manifold of constant curvature K_0 . Let $c: [a, b] \rightarrow N$ be an arclength parameterized curve with $\kappa_1, \dots, \kappa_{j-1}$ nowhere zero, and κ_j everywhere zero. Then c lies in some j -dimensional totally geodesic submanifold of N .

PROOF. Let $\mathbf{v}_1, \dots, \mathbf{v}_j$ be the Frenet frame for c , and let $\Delta(s) \subset M_{c(s)}$ be the subspace spanned by $\mathbf{v}_1(s), \dots, \mathbf{v}_j(s)$. The argument in the proof of Theorem 5 shows generally that Δ is parallel along c . So our result follows from Lemma 8. ♦

10. COROLLARY. Let N^m be a complete manifold of constant curvature K_0 . Let $c, \bar{c}: [a, b] \rightarrow N$ be arclength parameterized curves with $\kappa_1, \dots, \kappa_{j-1}$ and $\bar{\kappa}_1, \dots, \bar{\kappa}_{j-1}$ nowhere zero, and κ_j and $\bar{\kappa}_j$ everywhere zero. If $\kappa_i = \bar{\kappa}_i$ for $1 \leq i \leq j-1$, then there is an isometry $A: N \rightarrow N$ such that $\bar{c} = A \circ c$. The group of all such isometries is isomorphic to the orthogonal group $O(m-j-1)$.

PROOF. Left to the reader. ♦

For later use, we note a consequence of Lemma 8 for higher dimensional submanifolds M of N .

11. COROLLARY. Let N be a manifold of constant curvature K_0 . Let M be a connected submanifold immersed in N , and let Δ be a j -dimensional distribution along M such that $M_p \subset \Delta(p)$ for all $p \in M$. Suppose that Δ is parallel along every curve c in M . Then M lies in some j -dimensional totally geodesic submanifold $P \subset N$, and $\exp(\Delta(p)) \subset P$ for all $p \in M$.

PROOF. Choose a point $p_0 \in M$, and let P be the largest j -dimensional totally geodesic submanifold of N with $P \supset \exp(\Delta(p_0))$. For any $p \in M$, choose a curve $c: [0, 1] \rightarrow M$ with $c(0) = p_0$ and $c(1) = p$. Lemma 8, applied to the distribution $s \mapsto \Delta(c(s))$ along c , implies that c lies in some j -dimensional totally geodesic submanifold $P' \subset M$, and $\exp(\Delta(c(s))) \subset P'$ for all s . Applying this for $s = 0$, we see that $P' \subset P$. Hence $p \in P$, and also $\exp(\Delta(p)) = \exp(\Delta(c(1))) \subset P' \subset P$. ♦

C. THE FUNDAMENTAL EQUATIONS FOR SUBMANIFOLDS

In Chapter I, we considered a submanifold M^n of a Riemannian manifold $(N^m, \langle \cdot, \cdot \rangle)$ with $i: M \rightarrow N$ the inclusion map. For each $p \in M$, we have $N_p = M_p \oplus M_p^\perp$, and we used this decomposition to define two projections, $\mathbb{T}: N_p \rightarrow M_p$ and $\mathbb{L}: N_p \rightarrow M_p^\perp$. For vector fields X and Y tangent along M we wrote

$$\nabla'_{X_p} Y = \mathbb{T}(\nabla'_{X_p} Y) + \mathbb{L}(\nabla'_{X_p} Y)$$

where ∇' is the covariant differentiation in N , and we showed that $\mathbb{T}(\nabla'_{X_p} Y) = \nabla_{X_p} Y$, where ∇ is the covariant differentiation in M determined by the metric $i^*\langle \cdot, \cdot \rangle$, while $\mathbb{L}(\nabla'_{X_p} Y) = s(X_p, Y_p)$ is symmetric in X_p and Y_p (and independent of the extension Y of Y_p). This gave us

The Gauss Formulas: $\nabla'_{X_p} Y = \nabla_{X_p} Y + s(X_p, Y_p)$

and we then derived

Gauss' Equation:

$$\begin{aligned} \langle R'(X, Y)Z, W \rangle &= \langle R(X, Y)Z, W \rangle \\ &\quad + \langle s(X, Z), s(Y, W) \rangle - \langle s(Y, Z), s(X, W) \rangle \end{aligned}$$

for all tangent vectors $X, Y, Z, W \in M_p$. (For convenience we will often use X, Y, Z, \dots without subscripts to denote vectors as well as vector fields.)

For a *hypersurface* with a unit normal field ν , we showed that $\nabla'_{X_p} \nu \in M_p$, and we determined this vector explicitly by

$$\text{The Weingarten Equations:} \quad \langle \nabla'_{X_p} \nu, Y_p \rangle = -\langle \nu, s(X_p, Y_p) \rangle.$$

Defining a tensor Π by $s(X_p, Y_p) = \Pi(X_p, Y_p) \cdot \nu(p)$, we then derived the

Codazzi-Mainardi Equations:

$$\langle R'(X, Y)Z, \nu \rangle = (\nabla_X \Pi)(Y, Z) - (\nabla_Y \Pi)(X, Z).$$

Now we want to consider a submanifold of arbitrary codimension. We define the **normal bundle** $\text{Nor } M$ of M in N to be

$$\text{Nor } M = \bigcup_{p \in M} M_p^\perp,$$

and we define the projection map

$$\varpi: \text{Nor } M \rightarrow M$$

to be the one which takes all vectors in M_p^\perp to p . Thus (compare pg. I.344) $\varpi: \text{Nor } M \rightarrow M$ is a vector bundle whose fibre $\varpi^{-1}(p)$ over p is M_p^\perp . A section ξ of E is a map with $\xi(p) \in M_p^\perp$ for all p , in other words, a normal vector field along M .

Unlike the case of a hypersurface, it is no longer true that $\nabla'_{X_p} \xi \in M_p$, even if ξ always has length 1, so we will look at the general decomposition

$$\nabla'_{X_p} \xi = \mathsf{T}(\nabla'_{X_p} \xi) + \mathsf{L}(\nabla'_{X_p} \xi).$$

The tangential component is just as nice as in the case of hypersurfaces:

12. PROPOSITION. If ξ is a section of the normal bundle of M , and $X_p \in M_p$, then the vector $\mathsf{T}(\nabla'_{X_p} \xi) \in M_p$ satisfies

$$\langle \mathsf{T}(\nabla'_{X_p} \xi), Y_p \rangle = \langle \nabla'_{X_p} \xi, Y_p \rangle = -\langle \xi(p), s(X_p, Y_p) \rangle, \quad \text{for all } Y_p \in M_p.$$

Consequently, $\mathsf{T}(\nabla'_{X_p} \xi)$ depends only on X_p and $\xi(p)$.

PROOF. If Y is a vector field tangent along M which extends Y_p , then $\langle \xi, Y \rangle = 0$, so

$$\begin{aligned} 0 &= X_p(\langle \xi, Y \rangle) = \langle \nabla'_{X_p} \xi, Y_p \rangle + \langle \xi(p), \nabla'_{X_p} Y \rangle \\ &= \langle \nabla'_{X_p} \xi, Y_p \rangle + \langle \xi(p), s(X_p, Y_p) \rangle, \end{aligned}$$

since $\xi(p) \in M_p^\perp$, by assumption. ♦

For any vector $\xi_p \in M_p^\perp$, we will define $A_{\xi_p}: M_p \rightarrow M_p$ as follows. For each $X_p \in M_p$, we let $A_{\xi_p}(X_p) \in M_p$ be the unique vector satisfying

$$\langle A_{\xi_p}(X_p), Y_p \rangle = \langle s(X_p, Y_p), \xi_p \rangle \quad \text{for all } Y_p \in M_p.$$

By Proposition 12, we also have

$$A_{\xi_p}(X_p) = -\mathsf{T}(\nabla'_{X_p} \xi),$$

where ξ is any normal vector field extending ξ_p . When M is a hypersurface in \mathbb{R}^{n+1} with unit normal vector field v , the map $A_{v_p}: M_p \rightarrow M_p$ is the same as $-dv: M_p \rightarrow M_p$.

For the normal component $\perp(\nabla'_{X_p} \xi)$ we will simply introduce a new symbol, just as we did for $\perp(\nabla'_{X_p} Y)$. For a section ξ of the normal bundle of M , and for $X_p \in M_p$, we define

$$D_{X_p} \xi = \perp(\nabla'_{X_p} \xi) \in M_p^\perp.$$

Unlike the case of $\perp(\nabla'_{X_p} Y)$, the value of $\perp(\nabla'_{X_p} \xi)$ depends on the values of ξ in a neighborhood of p , not just on $\xi(p)$.

13. PROPOSITION. The map $(X_p, \xi) \mapsto D_{X_p} \xi$ is a connection on the normal bundle $\text{Nor } M$; that is (compare pg. II.227 and also pg. II.346),

- (1) $D_{X_p+Y_p} \xi = D_{X_p} \xi + D_{Y_p} \xi$
- (2) $D_{X_p}(\xi + \eta) = D_{X_p} \xi + D_{X_p} \eta$
- (3) $D_{aX_p} \xi = a D_{X_p} \xi$ for all $a \in \mathbb{R}$
- (4) $D_{X_p} f \cdot \xi = f(p) \cdot D_{X_p} \xi + X_p(f) \cdot \xi(p)$ for all C^∞ functions f
- (5) If X is a C^∞ vector field and ξ is a C^∞ section of the normal bundle, then $p \mapsto D_{X_p} \xi$ is also C^∞ .

Moreover, D is compatible with the metric $\langle \cdot, \cdot \rangle$ on the normal bundle:

$$X_p(\langle \xi, \eta \rangle) = \langle D_{X_p} \xi, \eta \rangle + \langle \xi, D_{X_p} \eta \rangle.$$

PROOF. All properties follow immediately from the corresponding properties for ∇' . ♦

We will call D the **normal connection** for the imbedding $M \subset N$. With the notation we have just introduced, we may now write the decomposition $\nabla'_{X_p} \xi = \mathbf{T}(\nabla'_{X_p} \xi) + \mathbf{L}(\nabla'_{X_p} \xi)$ as

The Weingarten Equations: $\nabla'_{X_p} \xi = -A_{\xi_p}(X_p) + D_{X_p} \xi.$

In the case of a hypersurface, we used the second fundamental form s and a unit normal vector field v to define a real-valued second fundamental form \mathbf{II} . In the general case, we choose v_{n+1}, \dots, v_m to be everywhere orthonormal sections of E defined in a neighborhood of a point and we define $m - n$ real-valued **second fundamental forms** \mathbf{II}' by

$$\mathbf{II}'(X_p, Y_p) = \langle \nabla'_{X_p} Y_p, v_r(p) \rangle = \langle s(X_p, Y_p), v_r(p) \rangle \quad r = m + 1, \dots, n.$$

We thus have

$$s(X_p, Y_p) = \sum_r \mathbf{II}'(X_p, Y_p) \cdot v_r(p).$$

Notice that the set $\{\mathbf{II}'\}$ depends on the choice of the $\{v_r\}$; there are many possible choices, unlike the case of a hypersurface, where the choice of the single unit normal field v was essentially unique. Using the \mathbf{II}' instead of s , we can write

Gauss' Equation:

$$\begin{aligned} \langle R'(X, Y)Z, W \rangle &= \langle R(X, Y)Z, W \rangle \\ &+ \sum_r \{ \mathbf{II}'(X, Z) \mathbf{II}'(Y, W) - \mathbf{II}'(Y, Z) \mathbf{II}'(X, W) \}. \end{aligned}$$

Since the tensors \mathbf{II}' give us an explicit expression for s , they also essentially give us an expression for the $A_{v_r}(p)$, for the equation

$$\langle A_{v_r(p)}(X_p), Y_p \rangle = \langle v_r(p), s(X_p, Y_p) \rangle = \mathbf{II}'(X_p, Y_p)$$

determines $A_{v_r(p)}(X_p)$. We also want quantities by means of which we can express D . So we introduce certain 1-forms, the **normal fundamental forms** β_r^s , by

$$\beta_r^s(X_p) = \langle \nabla'_{X_p} v_r, v_s \rangle = \langle D_{X_p} v_r, v_s \rangle.$$

Then

$$D_{X_p} v_r = \sum_s \beta_r^s(X_p) \cdot v_s,$$

and $D_{X_p} \xi$ can be computed for any $\xi = \sum_r a^r v_r$ by using Proposition 13. Notice that since $\langle v_r, v_s \rangle = 1$ or 0 , we have $\beta_r^s = -\beta_s^r$. In particular, for hypersurfaces we have the single 1-form $\beta_{n+1}^{n+1} = 0$.

14. THEOREM. Let M be a submanifold of N , with corresponding s and D . Then for all vector fields X, Y, Z tangent along M we have

$$\begin{aligned} \perp(R'(X, Y)Z) &= [D_X(s(Y, Z)) - s(\nabla_X Y, Z) - s(Y, \nabla_X Z)] \\ &\quad - [D_Y(s(X, Z)) - s(\nabla_Y X, Z) - s(X, \nabla_Y Z)]. \end{aligned}$$

If ν_{n+1}, \dots, ν_m are everywhere orthonormal sections of $\text{Nor } M$, with corresponding Π^r and β_r^s , then for all vectors $X, Y, Z \in M_p$ we have

The Codazzi-Mainardi Equations:

$$\begin{aligned} \langle R'(X, Y)Z, \nu^r(p) \rangle &= (\nabla_X \Pi^r)(Y, Z) - (\nabla_Y \Pi^r)(X, Z) \\ &\quad + \sum_s \Pi^s(Y, Z) \beta_s^r(X) - \Pi^s(X, Z) \beta_s^r(Y). \end{aligned}$$

PROOF. The first equation is precisely equation (3) in the proof of Theorem I-11. Now Proposition 12 gives

$$\begin{aligned} (1) \quad D_X(s(Y, Z)) &= D_X\left(\sum_s \Pi^s(Y, Z) \nu_s\right) \\ &= \sum_s X(\Pi^s(Y, Z)) \cdot \nu_s + \sum_s \Pi^s(Y, Z) D_X \nu_s. \end{aligned}$$

Moreover,

$$(2) \quad s(\nabla_X Y, Z) + s(Y, \nabla_X Z) = \sum_s \Pi^s(\nabla_X Y, Z) \cdot \nu_s + \sum_s \Pi^s(Y, \nabla_X Z) \cdot \nu_s.$$

Then (1) and (2) give

$$\begin{aligned} (3) \quad &D_X(s(Y, Z)) - s(\nabla_X Y, Z) - s(Y, \nabla_X Z) \\ &= \sum_s [X(\Pi^s(Y, Z)) - \Pi^s(\nabla_X Y, Z) - \Pi^s(Y, \nabla_X Z)] \cdot \nu_s \\ &\quad + \sum_s \Pi^s(Y, Z) D_X \nu_s \\ &= \sum_s (\nabla_X \Pi^s)(Y, Z) \cdot \nu_s + \sum_s \Pi^s(Y, Z) D_X \nu_s \quad \text{by Corollary II.6-5*}. \end{aligned}$$

Hence

$$\begin{aligned} (4) \quad \langle D_X(s(Y, Z)) - s(\nabla_X Y, Z) - s(Y, \nabla_X Z), \nu_r \rangle \\ = (\nabla_X \Pi^r)(Y, Z) + \sum_s \Pi^s(Y, Z) \beta_s^r(X). \end{aligned}$$

*As on pg. III.11, we really need this Corollary for tensors of type $\binom{k}{0}$.

Naturally there is a similar equation with X and Y interchanged. Substituting into the first part of the Theorem, we obtain the Codazzi-Mainardi equations. ♦

The Codazzi-Mainardi equations which we have derived here are obviously a lot less satisfying than they were in the case of a hypersurface, since the set $\{\Pi'\}$ is not unique. As a matter of fact, the nicest form of the Codazzi-Mainardi equation is obtained by looking a little more closely at the expression

$$D_X(s(Y, Z)) - s(\nabla_X Y, Z) - s(Y, \nabla_X Z)$$

which appears in the first part of Theorem 14. A quick check shows that this expression is linear in X , Y , and Z over the C^∞ functions. So the value of this expression at p depends only on X_p, Y_p, Z_p . To obtain an explicit description of this function of three vectors, we consider s as a section of the bundle $\text{Hom}(TM \times TM, \text{Nor } M)$ whose fibre at p is the vector space of all bilinear maps $M_p \times M_p \rightarrow M_p^\perp$. Now, using the connection ∇ in TM and the connection D in $\text{Nor } M$, a connection $\tilde{\nabla}$ in the bundle $\text{Hom}(TM \times TM, \text{Nor } M)$ can be defined in the following natural way. Given

$$\begin{cases} \text{a section } \psi \text{ of } \text{Hom}(TM \times TM, \text{Nor } M), \\ \text{a vector } X_p \in M_p, \end{cases}$$

we want to have a bilinear map

$$\tilde{\nabla}_{X_p} \psi : M_p \times M_p \rightarrow M_p^\perp,$$

so we want to define

$$(\tilde{\nabla}_{X_p} \psi)(Y_p, Z_p), \quad \text{for } Y_p, Z_p \in M_p.$$

Let c be a curve in M with $c'(0) = X_p$, and let

$$\begin{aligned} \tau_h &= \text{the parallel translation in } TM \text{ along } c \\ &\quad \text{from } c(0) \text{ to } c(h) \text{ determined by } \nabla, \\ \rho_h &= \text{the parallel translation in } \text{Nor } M \text{ along } c \\ &\quad \text{from } c(0) \text{ to } c(h) \text{ determined by } D. \end{aligned}$$

Then we define

$$(\tilde{\nabla}_{X_p} \psi)(Y_p, Z_p) = \lim_{h \rightarrow 0} \frac{1}{h} [\rho_h^{-1}(\psi(c(h))(\tau_h Y_p, \tau_h Z_p)) - \psi(p)(Y_p, Z_p)].$$

[Notice that if $\text{Nor } M$ were just the trivial bundle $M \times \mathbb{R}$, making ψ essentially a tensor of type $\binom{2}{0}$, and D were the flat connection, with parallel translation the same along all curves, taking (p, a) to (q, a) for all $p, q \in M$ and $a \in \mathbb{R}$, then this definition would reduce to the definition of $\nabla_{X_p} \psi$ already given (pg. II.235). On the other hand, if $\text{Nor } M$ were TM , with the connection ∇ , then this definition would reduce to the definition of $\nabla_{X_p} \psi$ when ψ is a tensor of type $\binom{2}{1}$.] Now it is easy to see that if Y and Z are vector fields, then

$$(\tilde{\nabla}_{X_p} \psi)(Y_p, Z_p) = D_{X_p}(\psi(Y, Z)) - \psi(\nabla_{X_p} Y, Z_p) - \psi(Y_p, \nabla_{X_p} Z)$$

[Corollary II.6-5 is the special case when $\text{Nor } M$ is the trivial bundle]. We can therefore also express the Codazzi-Mainardi equations in an intrinsic form:

15. COROLLARY. Let M be a submanifold of N . Then for all vectors $X, Y, Z \in M_p$ we have

The Codazzi-Mainardi Equations:

$$\perp(R'(X, Y)Z) = (\tilde{\nabla}_X s)(Y, Z) - (\tilde{\nabla}_Y s)(X, Z)$$

where $\tilde{\nabla}$ is the covariant differentiation on $\text{Hom}(TM \times TM, \text{Nor } M)$ determined by the covariant differentiations ∇ on TM and D on the normal bundle $\text{Nor } M$.

The Gauss and Codazzi-Mainardi equations tell us what $\langle R'(X, Y)Z, W \rangle$ is when all four vectors are in M_p , or when three are in M_p and one is in M_p^\perp (which one doesn't matter, because the symmetry properties of R' allow us to express all possibilities in terms of the one where $W \in M_p^\perp$). We can just as well ask what $\langle R'(X, Y)Z, W \rangle$ is when two vectors are in M_p and two are in M_p^\perp . The answer is known (though not very well known) as the Ricci equations, or sometimes as the Ricci-Kühne equations. We need one more definition. Given $X, Y \in M_p$, and an orthonormal basis U_1, \dots, U_n of M_p , we set

$$\text{II}^r * \text{II}^s(X, Y) = \sum_{i=1}^n \text{II}^r(X, U_i) \cdot \text{II}^s(Y, U_i).$$

It is easy to check that $\text{II}^r * \text{II}^s$ does not depend on the choice of the orthonormal basis U_1, \dots, U_n . Classically, $\text{II}^r * \text{II}^s$ would be written as a contraction involving the components of II^r, II^s and the metric $\langle \cdot, \cdot \rangle^*$ on T^*M (compare pg. III.130).

16. THEOREM. Let M be a submanifold of N , with corresponding s , A , and D . Then for all vector fields X and Y tangent along M , and all sections ξ of the normal bundle $\text{Nor } M$ we have

$$\begin{aligned} \perp(R'(X, Y)\xi) &= s(A_\xi(X), Y) - s(A_\xi(Y), X) \\ &\quad + [D_X(D_Y\xi) - D_Y(D_X\xi) - D_{[X, Y]}\xi]. \end{aligned}$$

If v_{n+1}, \dots, v_m are everywhere orthonormal sections of $\text{Nor } M$, with corresponding Π^r and β_r^s , then for all vectors $X, Y \in M_p$ we have

The Ricci Equations:

$$\begin{aligned} \langle R'(X, Y)v_r(p), v_s(p) \rangle &= \Pi^r * \Pi^s(X, Y) - \Pi^r * \Pi^s(Y, X) \\ &\quad + (\nabla_X \beta_r^s)(Y) - (\nabla_Y \beta_r^s)(X) \\ &\quad + \sum_w \beta_w^s(X) \beta_r^w(Y) - \beta_w^s(Y) \beta_r^w(X). \end{aligned}$$

(Notice that these equations are trivial if M is a hypersurface.)

PROOF. The Weingarten equations and the Gauss formulas give

$$\begin{aligned} \nabla'_X(\nabla'_Y\xi) &= -\nabla'_X(A_\xi(Y)) + \nabla'_X(D_Y\xi) \\ &= -\nabla_X(A_\xi(Y)) - s(X, A_\xi(Y)) - A_{(D_Y\xi)}(X) + D_X(D_Y\xi), \end{aligned}$$

and hence

$$(1) \quad \perp(\nabla'_X(\nabla'_Y\xi)) = -s(X, A_\xi(Y)) + D_X(D_Y\xi),$$

$$(1') \quad \perp(\nabla'_Y(\nabla'_X\xi)) = -s(Y, A_\xi(X)) + D_Y(D_X\xi).$$

Also,

$$\nabla'_{[X, Y]}\xi = A_\xi([X, Y]) + D_{[X, Y]}\xi,$$

so

$$(2) \quad \perp(\nabla'_{[X, Y]}\xi) = D_{[X, Y]}\xi.$$

Equations (1), (1'), and (2) give the first part of the theorem.

Now if U_1, \dots, U_n is an orthonormal basis for M_p , then

$$\begin{aligned} A_{v_r(p)}(X_p) &= \sum_{i=1}^n \langle A_{v_r(p)}(X_p), U_i \rangle \cdot U_i \\ &= \sum_{i=1}^n \langle v_r(p), s(X_p, U_i) \rangle \cdot U_i \\ &= \sum_{i=1}^n \Pi^r(X_p, U_i) \cdot U_i, \end{aligned}$$

so

$$\begin{aligned}
 (3) \quad \langle s(A_{v_r(p)}(X_p), Y_p), v_s(p) \rangle &= \Pi^s(A_{v_r(p)}(X_p), Y_p) \\
 &= \Pi^s\left(\sum_{i=1}^n \Pi^r(X_p, U_i) \cdot U_i, Y_p\right) \\
 &= \sum_{i=1}^n \Pi^r(X_p, U_i) \cdot \Pi^s(Y_p, U_i) \\
 &= \Pi^r * \Pi^s(X_p, Y_p),
 \end{aligned}$$

$$(3') \quad \langle s(A_{v_r(p)}(Y_p), X_p), v_s(p) \rangle = \Pi^r * \Pi^s(Y_p, X_p).$$

We also have

$$\begin{aligned}
 D_X(D_Y v_r) &= \sum_w D_X(\beta_r^w(Y) \cdot v_w) \\
 &= \sum_w X(\beta_r^w(Y)) \cdot v_w + \sum_w \beta_r^w(Y) \cdot D_X v_w \\
 &= \sum_w X(\beta_r^w(Y)) \cdot v_w + \sum_w \beta_r^w(Y) \cdot \sum_v \beta_w^v(X) v_v,
 \end{aligned}$$

so

$$(4) \quad \langle D_X(D_Y v_r), v_s \rangle = X(\beta_r^s(Y)) + \sum_w \beta_w^s(X) \beta_r^w(Y),$$

$$(4') \quad \langle D_Y(D_X v_r), v_s \rangle = Y(\beta_r^s(X)) + \sum_w \beta_w^s(Y) \beta_r^w(X).$$

Also,

$$\begin{aligned}
 (5) \quad \langle D_{[X,Y]} v_r, v_s \rangle &= \langle D_{\nabla_X Y} v_r, v_s \rangle - \langle D_{\nabla_Y X} v_r, v_s \rangle \\
 &= \beta_r^s(\nabla_X Y) - \beta_r^s(\nabla_Y X).
 \end{aligned}$$

From (4), (4'), and (5) we get

$$\begin{aligned}
 (6) \quad &\langle D_X(D_Y v_r) - D_Y(D_X v_r) - D_{[X,Y]} v_r, v_s \rangle \\
 &= [X(\beta_r^s(Y)) - \beta_r^s(\nabla_X Y)] - [Y(\beta_r^s(X)) - \beta_r^s(\nabla_Y X)] \\
 &\quad + \sum_w \beta_w^s(X) \beta_r^w(Y) - \beta_w^s(Y) \beta_r^w(X) \\
 &= (\nabla_X \beta_r^s)(Y) - (\nabla_Y \beta_r^s)(X) + \sum_w \beta_w^s(Y) \beta_r^w(X) - \beta_w^s(X) \beta_r^w(Y) \\
 &\quad \text{by Corollary II.6-5.}
 \end{aligned}$$

Substituting (3), (3'), (6) into the first part of the theorem, we obtain the Ricci equations. ♦

The expression $D_X(D_Y\xi) - D_Y(D_X\xi) - D_{[X,Y]}\xi$ which appears in the first part of Theorem 16 can be treated just like the expressions which arose in Theorem 14. In fact, for any connection D in any vector bundle $\varpi: E \rightarrow M$, the map

$$(X, Y, \xi) \mapsto D_X(D_Y\xi) - D_Y(D_X\xi) - D_{[X,Y]}\xi$$

(for vector fields X, Y on M and sections ξ of E) is linear in X, Y , and ξ over the C^∞ functions. Consequently, its value at $p \in M$ depends only on $X_p, Y_p, \xi(p)$: we already know this for the two vector fields X, Y (Theorem I.4-2), and the proof for the section ξ is essentially the same. We therefore have a well-defined map

$$R_D = R_D(p): M_p \times M_p \times \varpi^{-1}(p) \rightarrow \varpi^{-1}(p),$$

the **curvature** of the connection D , given by

$$R_D(p)(X_p, Y_p)\xi_p = D_X(D_Y\xi)(p) - D_Y(D_X\xi)(p) - D_{[X,Y]}\xi(p),$$

for any vector fields X and Y extending X_p and Y_p , and any section ξ of E with $\xi(p) = \xi_p$. Thus we can state a more intrinsic form of the Ricci equations:

17. COROLLARY. Let M be a submanifold of N , with corresponding s and A . Then for all vectors $X, Y \in M_p$ and $\xi \in M_p^\perp$ we have

The Ricci Equations:

$$\perp(R'(X, Y)\xi) = R_D(X, Y)\xi + s(A_\xi(X), Y) - s(A_\xi(Y), X)$$

where R_D is the curvature of the connection D in $\text{Nor } M$.

The Gauss, Codazzi-Mainardi, and Ricci equations are the only general equations which we have for submanifolds of a Riemannian manifold. It would not be reasonable to expect an interesting formula for $\langle R'(X, Y)Z, W \rangle$ when *three* of the vectors are in M_p^\perp . For if $X, Y, Z \in M_p^\perp$, then $R'(X, Y, Z)$ has nothing to do with M at all, and $\langle R'(X, Y)Z, W \rangle$ would depend only on the position of M_p . The classical reason for resting content with these three equations was somewhat different. In Chapter 2 we saw (at least in a special case) that the Gauss and Codazzi-Mainardi equations were precisely the integrability conditions for the Gauss formulas. It turned out that the integrability conditions for the Weingarten equations reduced to the Codazzi-Mainardi equations, but this was only because we happened to be dealing with a hypersurface. In general, the integrability conditions for the Weingarten equations lead to two

sets of equations; one set reduces to the Codazzi-Mainardi equations, while the other set is precisely the Ricci equations [notice that our proof of Theorem 16 essentially investigated integrability conditions also, for we compared $\nabla'_X(\nabla'_Y\xi)$ with $\nabla'_Y(\nabla'_X\xi)$]. It was therefore clear to classical differential geometers that the Π^r and β_r^s determine an n -dimensional submanifold of \mathbb{R}^m up to Euclidean motion, and that any set of Π^r and β_r^s comes from some submanifold if the three fundamental equations are satisfied. In order to derive these results without writing everything out in very classical terms, we will first see what our fundamental equations say in terms of moving frames.

Consider an adapted orthonormal moving frame $X_1, \dots, X_n, X_{n+1}, \dots, X_m$ on M . As in Chapter 1, we let θ^i , ω_j^i , and Ω_j^i be the dual forms, connection forms, and curvature forms on M for the frame X_1, \dots, X_n , and we let ϕ^α , ψ_β^α , and Ψ_β^α be the forms on N for the frame X_1, \dots, X_m . Then on TM we have

$$\phi^i = \theta^i, \quad \phi^r = 0.$$

By looking at the first structural equations, we found that

$$\psi_j^i = \omega_j^i,$$

and that there are unique functions s_{ij}^r on M satisfying

$$\psi_j^r = \sum_i s_{ij}^r \theta^i, \quad s_{ij}^r = s_{ji}^r.$$

These functions are related to s by the equation (pg. III.19)

$$s(X_j, Y_k) = \sum_r s_{jk}^r X_r.$$

So if we choose the orthonormal vectors X_{n+1}, \dots, X_m to be our v_{n+1}, \dots, v_m , then the Π^r are given simply by

$$(a) \quad \Pi^r(X_r, X_k) = s_{kr}^r \implies \psi_j^r(X) = \Pi^r(X, X_j),$$

while the normal forms β_r^s are simply

$$(b) \quad \beta_r^s = \psi_r^s \quad \text{on } TM.$$

Since the map A is determined by

$$\begin{aligned} \langle A_{v_r}(X_i), X_j \rangle &= \langle v_r, s(X_i, X_j) \rangle \\ &= s_{ij}^r, \end{aligned}$$

we also have the explicit formula

$$A_{v_r}(X_i) = \sum_j s_{ij}^r X_j.$$

More important, we have

$$\begin{aligned} \text{(c)} \quad \Pi^r * \Pi^s(X_i, X_j) &= \sum_{k=1}^n \Pi^r(X_i, X_k) \Pi^s(X_j, X_k) \\ &= \sum_{k=1}^n s_{ik}^r s_{jk}^s. \end{aligned}$$

Now let us look at the second structural equation

$$d\psi_\beta^\alpha = - \sum_\gamma \psi_\lambda^\alpha \wedge \psi_\beta^\lambda + \Psi_\beta^\alpha.$$

If we restrict to TM , and choose various ranges for the indices, we obtain the following three equations (for the first we also use the structural equation on M , as in Chapter 1):

$$\text{(A)} \quad \Psi_j^i = \Omega_j^i - \sum_r \psi_i^r \wedge \psi_j^r$$

$$\text{(B)} \quad d\psi_j^r = - \sum_i \psi_i^r \wedge \omega_j^i - \sum_w \psi_w^r \wedge \psi_j^w + \Psi_j^r$$

$$\text{(C)} \quad d\psi_r^s = \sum_i \psi_i^s \wedge \psi_r^i - \sum_w \psi_w^s \wedge \psi_r^w + \Psi_r^s.$$

Using equation (a) we see immediately that equation (A) is precisely equivalent to Gauss' equation (in the form given on page 32). For equations (B) and (C) we recall that for a 1-form η we have (pg. I.215)

$$\text{(d)} \quad d\eta(X_k, X_l) = X_k(\eta(X_l)) - X_l(\eta(X_k)) - \eta([X_k, X_l]).$$

We also have

$$\text{(e)} \quad [X_k, X_l] = \nabla_{X_k} X_l - \nabla_{X_l} X_k = \sum_i \omega_l^i(X_k) X_i - \omega_k^i(X_l) X_i$$

and (Corollary II.6-5)

$$\text{(f)} \quad (\nabla_{X_k} \Pi^r)(X_l, X_j) = X_k(\Pi^r(X_l, X_j)) - \Pi^r(\nabla_{X_k} X_l, X_j) - \Pi^r(X_l, \nabla_{X_k} X_j)$$

$$\text{(g)} \quad (\nabla_{X_k} \beta_r^s)(X_l) = X_k(\beta_r^s(X_l)) - \beta_r^s(\nabla_{X_k} X_l).$$

When we apply equations (B) and (C) to (X_k, X_l) , and use equations (a)–(g), we find that (B) and (C) are equivalent to the Codazzi-Mainardi equations in Theorem 14, and the Ricci equations in Theorem 16, respectively. Equations (A), (B), (C), involving differential forms, are much more convenient for considering questions connected with integrability conditions.

18. THEOREM. (1) Let $M, \bar{M} \subset \mathbb{R}^m$ be two connected n -manifolds imbedded in \mathbb{R}^m , let v_{n+1}, \dots, v_m be everywhere orthonormal sections for the normal bundle of M , and let $\bar{v}_{n+1}, \dots, \bar{v}_m$ be everywhere orthonormal sections for the normal bundle of \bar{M} . Let I, II^r, β_r^s be the first, second, and normal fundamental forms for M (defined with respect to the $\{v^r\}$), and define $\bar{I}, \bar{II}^r, \bar{\beta}_r^s$ similarly. Let $\phi: M \rightarrow \bar{M}$ be a diffeomorphism which preserves all the fundamental forms:

$$\phi^* \bar{I} = I, \quad \phi^* \bar{II}^r = II^r, \quad \phi^* \bar{\beta}_r^s = \beta_r^s.$$

Then there is a Euclidean motion A such that $\phi = A|M$ and $A_*(v_r) = \bar{v}_r$ for $r = n+1, \dots, m$.

(2) Let $(M, \langle \cdot, \cdot \rangle)$ be an n -dimensional Riemannian manifold with curvature tensor R . For $r, s = n+1, \dots, m$, let S^r be symmetric tensors on M , covariant of order 2, and let b_r^s be 1-forms on M with $b_r^s = -b_s^r$. Suppose that the S^r and b_r^s satisfy

(1) Gauss' Equation:

$$0 = \langle R(X, Y)Z, W \rangle - \sum_r S^r(Y, Z)S^r(X, W) + S^r(X, Z)S^r(Y, W)$$

(2) The Codazzi-Mainardi Equations:

$$\begin{aligned} 0 &= (\nabla_X S^r)(Y, Z) - (\nabla_Y S^r)(X, Z) \\ &\quad + \sum_s \{S^s(Y, Z)b_s^r(X) - S^s(X, Z)b_s^r(Y)\} \end{aligned}$$

(3) The Ricci Equations:

$$\begin{aligned} 0 &= S^r * S^s(X, Y) - S^r * S^s(Y, X) + (\nabla_X b_r^s)(Y) - (\nabla_Y b_r^s)(X) \\ &\quad + \sum_w \{b_w^s(X)b_r^w(Y) - b_w^s(Y)b_r^w(X)\}. \end{aligned}$$

Then for every point of M there is a neighborhood U and an isometric imbedding $f: U \rightarrow \mathbb{R}^m$ such that there are everywhere orthonormal sections v_{n+1}, \dots, v_m of the normal bundle of $f(U)$ in \mathbb{R}^m for which the corresponding forms II^r and β_r^s on $f(U)$ satisfy

$$s^r = f^* II^r, \quad b_r^s = f^* \beta_r^s.$$

PROOF. We will consider the proof of (2) first, since the proof of (1) will come along for free. Since we are trying to prove a local result, we might as well

assume that M is \mathbb{R}^n . Let X_1, \dots, X_n be an orthonormal moving frame for $\langle \cdot, \cdot \rangle$ on \mathbb{R}^n , with dual forms θ^i , and connection forms ω_j^i . Define 1-forms ψ_β^α ($1 \leq \alpha, \beta \leq m$) on \mathbb{R}^n as follows:

$$\begin{aligned}\psi_j^i &= \omega_j^i & 1 \leq i, j \leq n \\ \psi_j^r(X) &= S^r(X, X_j) & 1 \leq j \leq n < r \leq m \\ \psi_s^r &= b_s^r & n < r, s \leq m.\end{aligned}$$

Then the forms ψ_β^α satisfy two crucial equations:

$$(*) \quad \sum_{j=1}^n \psi_j^r \wedge \theta^j = 0 \quad r = n+1, \dots, m$$

$$(**) \quad d\psi_\beta^\alpha = - \sum_{\gamma=1}^m \psi_\gamma^\alpha \wedge \psi_\beta^\gamma \quad \alpha, \beta = 1, \dots, m.$$

Equation (*) follows directly from the definition of ψ_j^r and symmetry of S^r . Equation (**) follows from the Gauss, Codazzi-Mainardi, and Ricci equations in the hypothesis. This should be clear from our verifications, prior to the statement of the theorem, that equations (A), (B), and (C) are equivalent to Gauss' equation on page 32, and to the Codazzi-Mainardi equations in Theorem 14 and 16, respectively.

Now suppose for the moment that we have an immersion $f: (\mathbb{R}^n, \langle \cdot, \cdot \rangle) \rightarrow \mathbb{R}^m$, and orthonormal sections v_{n+1}, \dots, v_m of the normal bundle of $f(\mathbb{R}^n)$. Identifying tangent vectors of \mathbb{R}^m with elements of \mathbb{R}^m , as usual, we thus have a map

$$v = (v_1, \dots, v_m) = (f_*(X_1), \dots, f_*(X_n), v_{n+1}, \dots, v_m): \mathbb{R}^n \rightarrow \mathbb{R}^{m^2}.$$

If f is an isometry and $S^r = f^* \Pi^r$ and $b_r^s = f^* \beta_r^s$, then the components v_α^β of the functions v_α will satisfy

$$(1) \quad dv_\alpha^\beta = \sum_{\gamma=1}^m v_\gamma^\beta \cdot \psi_\alpha^\gamma.$$

So we will first show that a map $v = (v_1, \dots, v_m): \mathbb{R}^n \rightarrow \mathbb{R}^{m^2}$ satisfying (1) can be found. The idea of the proof is to look for the graph $\Gamma \subset \mathbb{R}^n \times \mathbb{R}^{m^2}$ of v (compare pg. II.264). Let $\pi_1: \mathbb{R}^n \times \mathbb{R}^{m^2} \rightarrow \mathbb{R}^n$ and $\pi_2: \mathbb{R}^n \times \mathbb{R}^{m^2} \rightarrow \mathbb{R}^{m^2}$ be the projections on the first and second factors, and let $\{x_\alpha^\beta\}$ be the standard coordinate system on \mathbb{R}^{m^2} . It is easy to see that if $v: \mathbb{R}^n \rightarrow \mathbb{R}^{m^2}$ satisfying (1)

exists, then its graph $\Gamma \subset \mathbb{R}^n \times \mathbb{R}^{m^2}$ is a submanifold on which the m^2 linearly independent 1-forms

$$(2) \quad d(x_\alpha^\beta \circ \pi_2) - \sum_{\gamma=1}^m (x_\gamma^\beta \circ \pi_2) \cdot \pi_1^* \psi_\alpha^\gamma$$

all vanish. Conversely, if all these 1-forms vanish on an n -dimensional manifold $\Gamma \subset \mathbb{R}^n \times \mathbb{R}^{m^2}$, then Γ is the graph of the desired function v . So by the Frobenius integrability theorem (I.7-14), we just have to show that the exterior derivative of each form (2) is in the ideal \mathcal{I} generated by these forms. Now

$$\begin{aligned} d\left(\sum_{\gamma=1}^m (x_\gamma^\beta \circ \pi_2) \cdot \pi_1^* \psi_\alpha^\gamma\right) &= \sum_{\gamma=1}^m d(x_\gamma^\beta \circ \pi_2) \wedge \pi_1^* \psi_\alpha^\gamma \\ &\quad + \sum_{\lambda=1}^m (x_\lambda^\beta \circ \pi_2) \cdot \pi_1^* d\psi_\alpha^\lambda \\ &= \sum_{\gamma=1}^m d(x_\alpha^\beta \circ \pi_2) \wedge \pi_1^* \psi_\alpha^\gamma \\ &\quad - \sum_{\gamma=1}^m (x_\gamma^\beta \circ \pi_2) \cdot \left(\sum_{\lambda=1}^m \pi_1^* \psi_\gamma^\lambda \wedge \pi_1^* \psi_\alpha^\gamma\right) \text{ by } (**) \\ &= \sum_{\gamma=1}^m \left(d(x_\alpha^\beta \circ \pi_2) - \sum_{\lambda=1}^m (x_\lambda^\beta \circ \pi_2) \cdot \pi_1^* \psi_\gamma^\lambda\right) \wedge \pi_1^* \psi_\alpha^\gamma, \end{aligned}$$

which is indeed in the ideal \mathcal{I} generated by the forms (2). Thus we see that there is a function $v: \mathbb{R}^n \rightarrow \mathbb{R}^{m^2}$ satisfying (I). In fact, we can choose $v(0)$ to be any linearly independent set of vectors in \mathbb{R}^{m^2} (just choose the integral submanifold of $\mathcal{I} = 0$ which passes through this set of vectors); in particular, we can choose $v(0)$ to be a set of orthonormal vectors.

We next note that, for the ordinary inner product $\langle \cdot, \cdot \rangle$ on \mathbb{R}^m , the functions v_1, \dots, v_m satisfy

$$\begin{aligned} d(\langle v_\alpha, v_\beta \rangle) &= \langle dv_\alpha, v_\beta \rangle + \langle v_\alpha, dv_\beta \rangle \\ &= \sum_{\gamma=1}^m v_\beta^\gamma \cdot dv_\alpha^\gamma + \sum_{\gamma=1}^m v_\alpha^\gamma \cdot dv_\beta^\gamma \\ &= \sum_{\gamma, \lambda=1}^m v_\beta^\gamma v_\lambda^\gamma \psi_\alpha^\lambda + \sum_{\gamma, \lambda=1}^m v_\alpha^\gamma v_\lambda^\gamma \psi_\beta^\lambda \quad \text{by (1)} \\ &= \sum_{\lambda=1}^m \langle v_\beta, v_\lambda \rangle \psi_\alpha^\lambda + \sum_{\lambda=1}^m \langle v_\alpha, v_\lambda \rangle \psi_\beta^\lambda. \end{aligned}$$

In particular, for any curve c in \mathbb{R}^m , the functions

$$f_{\alpha\beta}(t) = \langle v_\alpha(c(t)), v_\beta(c(t)) \rangle$$

satisfy the differential equation

$$f_{\alpha\beta}'(t) = \sum_{\lambda=1}^m \psi_\alpha^\lambda(c'(t)) f_{\beta\lambda}(t) + \sum_{\lambda=1}^m \psi_\beta^\lambda(c'(t)) f_{\alpha\lambda}(t).$$

Since $\psi_\beta^\alpha = -\psi_\alpha^\beta$, this same equation is satisfied by the functions $f_{\alpha\beta}(t) = \delta_{\alpha\beta}$. So by uniqueness of solutions with a given initial condition, we conclude that v_1, \dots, v_m are orthonormal everywhere.

Now we want to show that there is actually a function $f: \mathbb{R}^n \rightarrow \mathbb{R}^m$ such that

$$f_*(X_i) = v_i \quad i = 1, \dots, n.$$

For the component functions f^1, \dots, f^m of f we want

$$df^\alpha(X_i(p)) = v_i^\alpha(p) \quad \text{i.e.,} \quad df^\alpha(p) = \sum_{j=1}^n v_j^\alpha(p) \cdot \theta^j(p).$$

To prove that f exists, we look for its graph $\Gamma \subset \mathbb{R}^n \times \mathbb{R}^m$. We let $\pi_1: \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}^n$ and $\pi_2: \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}^m$ be the projections on the first and second factors, and we let $\{x^\alpha\}$ be the standard coordinate system on \mathbb{R}^m . The Γ we are seeking is a submanifold of $\mathbb{R}^n \times \mathbb{R}^m$ on which the 1-forms

$$(3) \quad d(x^\alpha \circ \pi_2) - \sum_{j=1}^n (v_j^\alpha \circ \pi_1) \cdot \pi_1^* \theta^j$$

all vanish. Now

$$\begin{aligned} d\left(\sum_{j=1}^n (v_j^\alpha \circ \pi_1) \cdot \pi_1^* \theta^j\right) &= \sum_{j=1}^n \pi_1^* dv_j^\alpha \wedge \pi_1^* \theta^j \\ &\quad - \sum_{i=1}^n (v_i^\alpha \circ \pi_1) \cdot \sum_{j=1}^n \pi_1^* \omega_j^i \wedge \pi_1^* \theta^j \\ &= \sum_{j=1}^n \sum_{\gamma=1}^m (v_\gamma^\alpha \circ \pi_1) \cdot \pi_1^* \psi_j^\gamma \wedge \pi_1^* \theta^j \\ &\quad - \sum_{i,j=1}^n (v_i^\alpha \circ \pi_1) \cdot \pi_1^* \omega_j^i \wedge \pi_1^* \theta^j \quad \text{by (1)} \\ &= \sum_{j=1}^n \sum_{r=n+1}^m (v_r^\alpha \circ \pi_1) \cdot \pi_1^* \psi_j^r \wedge \pi_1^* \theta^j \\ &= 0 \quad \text{by (*).} \end{aligned}$$

So the Frobenius integrability theorem proves that there is $f: \mathbb{R}^n \rightarrow \mathbb{R}^m$ with $f_*(X_i) = v_i$ ($i = 1, \dots, n$). Then f is an isometry, since X_1, \dots, X_n and v_1, \dots, v_n are both orthonormal sets. This proves part (2).

As for part (1), we first note that the required Euclidean motion A , if it exists, is unique [for if $p \in M$, then $A_*|M_p$ must be ϕ_{*p} , and $A_*(v_r(p))$ must be $\bar{v}_r(p)$]. Therefore it suffices to prove existence of A locally. By the usual argument, it suffices to show that $M = \bar{M}$ if for some $p \in M$ we have $p = \phi(p)$ and $M_p = \bar{M}_p$, and $\phi_{*p} = \text{identity}$ and $v_r(p) = \bar{v}_r$. But this follows immediately from the fact that there is just one function $v: \mathbb{R}^n \rightarrow \mathbb{R}^{m^2}$ satisfying (1), with a given value of $v(0)$. ♦

This classical formulation of Theorem 18 was given in order to emphasize the extra problems which arise when the codimension is greater than 1. But it is a very unsatisfactory way of bringing the normal bundle into the picture. After all, everywhere orthonormal sections v_{m+1}, \dots, v_n of the normal bundle can usually be found only in a neighborhood of each point. So the first part of Theorem 18 really makes sense only locally, even though it is supposed to be global. We have similar problems in the second part, where we would like to obtain a global result when M is simply connected. These defects are easily rectified, since we also have invariant statements of our fundamental equations. We need one simple bit of terminology. Let M and \bar{M} be C^∞ manifolds, and let $\varpi: E \rightarrow M$ and $\bar{\varpi}: \bar{E} \rightarrow \bar{M}$ be C^∞ vector bundles of the same dimension over M and \bar{M} , respectively. If $\phi: M \rightarrow \bar{M}$ is a diffeomorphism, then a C^∞ map $\tilde{\phi}: E \rightarrow \bar{E}$ is called a **bundle isomorphism covering ϕ** if:

(1) the diagram

$$\begin{array}{ccc} E & \xrightarrow{\tilde{\phi}} & \bar{E} \\ \varpi \downarrow & & \downarrow \bar{\varpi} \\ M & \xrightarrow{\phi} & \bar{M} \end{array}$$

commutes, so that $\tilde{\phi}$ takes $\varpi^{-1}(p)$ to $\bar{\varpi}^{-1}(\phi(p))$,

(2) each map

$$\tilde{\phi}|_{\varpi^{-1}(p)}: \varpi^{-1}(p) \rightarrow \bar{\varpi}^{-1}(\phi(p))$$

is a vector space isomorphism.

It then follows easily that $\tilde{\phi}$ is a diffeomorphism. Notice that if ξ is a section of E , then we have a section $\tilde{\phi}(\xi)$ of \bar{E} defined by

$$\tilde{\phi}(\xi)(q) = \tilde{\phi}(\xi(\phi^{-1}(q))) \quad q \in \bar{M}.$$

19. THEOREM. (1) Let M be a connected submanifold of \mathbb{R}^m with normal bundle $\varpi: \text{Nor } M \rightarrow M$, and corresponding second fundamental form s and normal connection D . Similarly, let \bar{M} be a connected submanifold with normal bundle $\bar{\varpi}: \text{Nor } \bar{M} \rightarrow \bar{M}$ and corresponding \bar{s} and \bar{D} . Let $\phi: M \rightarrow \bar{M}$ be an isometry. Suppose that there is a bundle isomorphism $\tilde{\phi}: \text{Nor } M \rightarrow \text{Nor } \bar{M}$ covering ϕ such that $\tilde{\phi}$ preserves inner products, second fundamental forms, and normal connections:

$$\begin{aligned} \langle \tilde{\phi}(\xi), \tilde{\phi}(\eta) \rangle &= \langle \xi, \eta \rangle & \text{for all } \xi, \eta \in M_p^\perp \\ \tilde{\phi}(s(X, Y)) &= \bar{s}(\phi_* X, \phi_* Y) & \text{for all } X, Y \in M_p \\ \tilde{\phi}(D_X \xi) &= \bar{D}_{\phi_* X}(\tilde{\phi}(\xi)) & \text{for all } X \in M_p \text{ and all sections } \xi \text{ of } \text{Nor } M. \end{aligned}$$

Then there is a Euclidean motion A such that $\phi = A|_M$ and $\tilde{\phi} = A_*|_{\text{Nor } M}$.

(2) Let $(M, \langle \cdot, \cdot \rangle)$ be a simply-connected n -dimensional Riemannian manifold, with covariant differentiation ∇ and curvature tensor R . Let $\varpi: E \rightarrow M$ be an $(m-n)$ -dimensional vector bundle over M with a Riemannian metric $\{ \cdot, \cdot \}$, let δ be a connection on E compatible with $\{ \cdot, \cdot \}$, with curvature tensor R_δ , and let σ be a symmetric section of the bundle $\text{Hom}(TM \times TM, E)$. Denote by $\tilde{\nabla}$ the connection on $\text{Hom}(TM \times TM, E)$ determined by ∇ and δ ; and for $X \in M_p$ and $\xi \in \varpi^{-1}(p)$, let $A_\xi(X) \in M_p$ be the unique vector satisfying

$$\langle A_\xi(X), Y \rangle = \{ \xi, \sigma(X, Y) \} \quad \text{for all } Y \in M_p.$$

Suppose that σ and δ satisfy

(1) Gauss' Equation:

$$\langle R(X, Y)Z, W \rangle = \{ \sigma(Y, Z), \sigma(X, W) \} - \{ \sigma(X, Z), \sigma(Y, W) \}$$

(2) The Codazzi-Mainardi equations:

$$(\tilde{\nabla}_X \sigma)(Y, Z) = (\tilde{\nabla}_Y \sigma)(X, Z)$$

(3) The Ricci equations:

$$R_\delta(X, Y)\xi = \sigma(A_\xi(Y), X) - \sigma(A_\xi(X), Y).$$

Then there is an isometric immersion $f: M \rightarrow \mathbb{R}^m$ and a bundle isomorphism $\tilde{f}: E \rightarrow \{\text{normal bundle of } f(M)\}$ covering f such that

$$\begin{aligned} \langle \tilde{f}(\xi), \tilde{f}(\eta) \rangle &= \langle \xi, \eta \rangle & \text{for all } \xi, \eta \in \varpi^{-1}(p) \\ \tilde{f}(\sigma(X, Y)) &= s(f_* X, f_* Y) & \text{for all } X, Y \in M_p \\ \tilde{f}(\delta_X \xi) &= D_{\phi_* X}(\tilde{f}(\xi)) & \text{for all } X \in M_p \text{ and all sections } \xi \text{ of } E, \end{aligned}$$

where s and D are the second fundamental form and the normal connection for $f(M)$.

PROOF. It's just one big translation job locally. Then simple-connectivity is used to prove the global result, as in Problem 2-3. ♦

Naturally, Theorem 19 simplifies considerably for the case of hypersurfaces, when $\text{Nor } M$ is 1-dimensional. In part (1) we can dispense with the normal connection D , and in part (2) we can dispense with δ (and the Ricci equations). When we deal with *oriented* hypersurfaces, we can ignore $\text{Nor } M$ completely, since the orientation of M determines a unit normal field v , and thus a second fundamental form Π . In part (1), we simply need that ϕ is an isometry with $\phi^*\bar{\Pi} = \Pi$; then the Euclidean motion A of the conclusion is actually a proper Euclidean motion with $A_*v = \bar{v}$. In part (2), we simply supply our Riemannian manifold $(M, \langle \cdot, \cdot \rangle)$ with a symmetric tensor S , covariant of order 2, satisfying

$$\begin{aligned}\langle R(X, Y)Z, W \rangle &= S(Y, Z) \cdot S(X, W) - S(X, Z) \cdot S(Y, W) \\ (\nabla_X S)(Y, Z) &= (\nabla_Y S)(X, Z).\end{aligned}$$

In the general case, Theorem 19 is much less satisfying, for it does *not* tell us when a map $\phi: M \rightarrow \bar{M}$ between two submanifolds of \mathbb{R}^m is the restriction of a Euclidean motion; it only gives us information about maps $\phi: M \rightarrow \bar{M}$ together with bundle isomorphisms $\tilde{\phi}: \text{Nor } M \rightarrow \text{Nor } \bar{M}$ covering ϕ (as a slight compensation, we find a Euclidean motion A preserving this additional structure). In the theory of curves we have a situation more closely resembling the case of hypersurfaces, since certain functions $\kappa_1, \dots, \kappa_{m-1}$ determine (“general”) curves parameterized by arclength. For curves in \mathbb{R}^m , the results of part B are actually a special case of Theorem 19, for the vector fields v_2, \dots, v_m along c give a trivialization of the normal bundle of c ; it is not hard to see (Problem 12) that if we choose $v_r = \mathbf{v}_r$, then the corresponding Π' and β_r^s are all expressible in terms of $\kappa_1, \dots, \kappa_{m-1}$. For higher dimensional submanifolds of higher codimension there is also a theory which determines “general” submanifolds, up to Euclidean motions, by means of tensors on the submanifold. Although this theory is certainly more appealing geometrically, it is rather elaborate, and is presented separately in Addendum 4.

For the present, we merely wish to generalize Theorem 19 by replacing \mathbb{R}^m with a more general ambient space. Now the first part of Theorem 19 simply isn't true for an arbitrary ambient space $(N, \langle \cdot, \cdot \rangle)$, which may not have any isometries onto itself except the identity. For example, we can easily construct a metric on \mathbb{R}^{n+1} such that the hypersurfaces $\mathbb{R}^n \times \{0\}$ and $\mathbb{R}^n \times \{1\}$ are isometric and have vanishing second fundamental forms, without there being any non-trivial isometry of \mathbb{R}^{n+1} onto itself, and in particular none taking $\mathbb{R}^n \times \{0\}$ to

$\mathbb{R}^n \times \{1\}$. It should be mentioned, however, that one can at least prove the following (Problem 12):

Suppose that M and \bar{M} are connected submanifolds of $(N, \langle \cdot, \cdot \rangle)$ and that there is a point $p \in M \cap \bar{M}$ with $M_p = \bar{M}_p$. Let $\phi: M \rightarrow \bar{M}$ be an isometry with $\phi(p) = p$ and $\phi_{*p}: M_p \rightarrow \bar{M}_p$ the identity. Suppose that there is a bundle isomorphism $\tilde{\phi}: \text{Nor } M \rightarrow \text{Nor } \bar{M}$ covering ϕ which preserves inner products, second fundamental forms, and normal connections, and such that $\tilde{\phi}$ is the identity map on M_p^\perp . Then $M = \bar{M}$ and ϕ is the identity.

We encounter difficulties of another sort when we try to generalize the second part of Theorem 19 for an arbitrary ambient manifold $(N, \langle \cdot, \cdot \rangle)$. Now we don't even know what conditions to place on δ and σ , since the Codazzi-Mainardi and Ricci equations for δ and σ involve terms $R'(X, Y)Z$ which we cannot evaluate unless we already have the imbedding of M into N .

These difficulties do not arise when $(N, \langle \cdot, \cdot \rangle)$ is a complete simply-connected manifold of constant curvature K_0 . The Euclidean motions of part (I) will be replaced by the isometries $A: N \rightarrow N$; such isometries can be found taking any orthonormal frame at one point of N to any orthonormal frame at any other point (Problem 1-5). Moreover, the Codazzi-Mainardi and Ricci equations for a submanifold $M \subset N$ are exactly the same as in the Euclidean case, since

$$R'(X, Y)Z = K_0[\langle Y, Z \rangle X - \langle X, Z \rangle Y] \quad (\text{pg. III.11})$$

$$\Downarrow$$

$$\perp(R'(X, Y)Z) = 0 \quad \text{for } X, Y, Z \text{ tangent to } M$$

$$R'(X, Y)\xi = 0 \quad \text{for } X, Y, Z \text{ tangent to } M \text{ and } \xi \text{ normal to } M.$$

Gauss' equation, on the other hand, becomes (Corollary 1-12)

$$\begin{aligned} K_0[\langle X, W \rangle \cdot \langle Y, Z \rangle - \langle X, Z \rangle \cdot \langle Y, W \rangle] \\ = \langle R(X, Y)Z, W \rangle + \langle s(X, Z), s(Y, W) \rangle - \langle s(Y, Z), s(X, W) \rangle. \end{aligned}$$

For an adapted orthonormal moving frame on M , equations (B) and (C) have $\Psi_j^r = \Psi_r^s = 0$, while equation (A) becomes

$$(A') \quad K_0[\theta^i \wedge \theta^j] = \Omega_j^i - \sum_r \psi_i^r \wedge \psi_j^r,$$

since

$$\begin{aligned} \Psi_j^i(X, Y) &= \langle R'(X, Y)X_j, X_i \rangle = K_0[\langle X, X_i \rangle \cdot \langle Y, X_j \rangle - \langle X, X_j \rangle \cdot \langle Y, X_i \rangle] \\ &= K_0[\theta^i(X)\theta^j(Y) - \theta^i(Y)\theta^j(X)]. \end{aligned}$$

One fairly straightforward method of generalizing Theorem 19 is to regard N as $S^m(K_0) \subset \mathbb{R}^{m+1}$, or as $H^m(K_0) \subset \mathbb{R}^{m+1}$ with the Lorentzian metric. The details of this pleasant proof are left to Problems 13 and 14, partly because it uses a result from the next section, but mainly because we want to provide a (rather unpleasant) proof which involves only the intrinsic description of N as a manifold of constant curvature K_0 . The proof of Theorem 19 itself will not generalize at all, because it involves the natural identification of $T\mathbb{R}^m$ with $\mathbb{R}^m \times \mathbb{R}^m$, an identification that essentially depends on the fact that \mathbb{R}^m is flat. For a general manifold $(N, \langle \cdot, \cdot \rangle)$ of constant curvature, we will have to consider the tangent bundle TN , and work with Ehresmann connections.

Consider a principal bundle $\pi: P \rightarrow M$ with group G . For each $X \in \mathfrak{g} = \text{Lie algebra of } G$, we have defined (pg. II.311) the **fundamental vector field** on P corresponding to X ; we will change notation slightly and denote this vector field by $\sigma(X)$ [so that σ can still be used as in the statement of Theorem 19]. Recall that an Ehresmann connection on P is a \mathfrak{g} -valued 1-form on P . We will use a bold face Greek letter, like ω , for such connections. Here our aim is to avoid confusing ω with the (closely related) connection forms ω_j^i of a moving frame on a manifold. Recall that a **frame** u for M_p is an ordered basis $u = (u_1, \dots, u_n)$ of M_p , and that we have a principal bundle $F(TM) \rightarrow M$ with group $\text{GL}(n, \mathbb{R})$, where $F(TM)$ is the set of all frames at all $p \in M$. An Ehresmann connection $\omega = (\omega_j^i)$ on $F(TM)$ is a $\mathfrak{gl}(n, \mathbb{R})$ -valued 1-form on $F(TM)$. For any moving frame $s = (X_1, \dots, X_n): U \rightarrow F(TM)$ on an open set $U \subset M$ we thus have the matrix of 1-forms $\omega = s^*\omega$, and the assignment of $\omega = s^*\omega$ to $s = (X_1, \dots, X_n)$ is a (Cartan) connection on M ; then by defining $\nabla_X X_j = \sum_i \omega_j^i(X) X_i$, we obtain a covariant differentiation operator ∇ on M . Conversely, every Cartan connection on M comes from a unique Ehresmann connection ω in this way, and thus every covariant differentiation operator ∇ comes from a unique ω . More generally, given a k -dimensional vector bundle $\varpi: E \rightarrow M$, we let $F(E) \rightarrow M$ denote the set of all ordered bases u of $\varpi^{-1}(p)$, for all $p \in M$. Then $F(E) \rightarrow M$ is a principal bundle with group $\text{GL}(k, \mathbb{R})$, and Ehresmann connections ω on $F(E)$ correspond to covariant differentiation operators $(X, \xi) \mapsto \nabla_X \xi$ on sections ξ of E . In the special case of $F(TM)$ we also have the \mathbb{R}^n -valued **dual form** $\theta = (\theta^1, \dots, \theta^n)$; for any moving frame $s = (X_1, \dots, X_n)$, the forms $\theta^i = s^*\theta^i$ are just the dual forms for this moving frame.

When we have a vector bundle $\varpi: E \rightarrow M$ which has a Riemannian metric $\langle \cdot, \cdot \rangle$, it is often more convenient to consider the bundle $O(E) \subset F(E)$ consisting of *orthonormal* frames. Notice that for $X \in \mathfrak{o}(k) \subset \mathfrak{gl}(k, \mathbb{R})$, the vector field $\sigma(X)$ on $O(E)$ is just the restriction of the vector field $\sigma(X)$ which is defined on

$F(E)$. Now suppose we have a covariant differentiation $(X, \xi) \mapsto \nabla_X \xi$ which is compatible with the metric $\{ , \}$, so that

$$X(\{\xi, \eta\}) = \{\nabla_X \xi, \eta\} + \{\xi, \nabla_X \eta\}.$$

If ξ_1, \dots, ξ_k are local sections of E with $\{\xi_i, \xi_j\} = \delta_{ij}$, and we define the 1-forms ω_j^i ($1 \leq i, j \leq k$) by

$$\nabla_X \xi_j = \sum_{i=1}^k \omega_j^i(X) \cdot \xi_i,$$

then we have

$$(I) \quad \omega_j^i = -\omega_i^j.$$

Let $\omega = (\omega_j^i)$ be the Ehresmann connection on $F(E)$ corresponding to the covariant differentiation ∇ . We claim that $\omega|_{O(E)}$ actually takes values in $\mathfrak{o}(k) = \{\text{skew-symmetric } k \times k \text{ matrices}\}$. In fact, if Y is a vertical vector at some $u \in O(E)$, then $Y = \sigma(X)(u)$ for some $X \in \mathfrak{o}(k)$, and

$$\omega(Y) = \omega(\sigma(X)(u)) = X \in \mathfrak{o}(k).$$

On the other hand, every non-vertical vector at a frame $u \in O(E)$ at $p \in M$ is of the form $s_*(Z)$ for some local orthonormal section $s = (\xi_1, \dots, \xi_k)$ and some tangent vector $Z \in M_p$, and then

$$\omega(s_*(Z)) = s^* \omega(Z) = \omega(Z),$$

so the claim follows from equation (I). Thus we see that $\omega|_{O(E)}$ is an Ehresmann connection on the principal bundle $O(E)$. [Conversely, an Ehresmann connection on $O(E)$ clearly extends in a natural way to an Ehresmann connection on $F(E)$ whose corresponding ∇ is compatible with the metric $\{ , \}$.] It is clear that at any point $u \in O(E)$, the horizontal subspace for the connection $\omega|_{O(E)}$ is exactly the same as the horizontal subspace at $u \in F(E)$ for the connection ω . So for $Y_1, Y_2 \in O(E)_u$, the covariant differential $D(\omega|_{O(E)})$ has value

$$\begin{aligned} D(\omega|_{O(E)})(Y_1, Y_2) &= d(\omega|_{O(E)})(hY_1, hY_2) \\ &= d\omega(hY_1, hY_2) \\ &= \Omega(Y_1, Y_2). \end{aligned} \quad \left\{ \begin{array}{l} hY_i = \text{horizontal} \\ \text{component of } Y_i \\ \text{in either } F(E) \\ \text{or } O(E) \end{array} \right.$$

In other words, the curvature form of $\omega|_{O(E)}$ is just the restriction to $O(E)$ of the curvature form Ω of ω . So no confusion will arise if we simply use ω for the restriction $\omega|_{O(E)}$, and Ω for the curvature form of $\omega|_{O(E)}$.

We will apply these considerations, in particular, to the case where $E = TM$ is the tangent bundle of a Riemannian manifold $(M^n, \langle \cdot, \cdot \rangle)$ and ω is the Ehresmann connection corresponding to the Levi-Civita connection for $\langle \cdot, \cdot \rangle$. Thus we have $\mathfrak{o}(n)$ -valued forms $\theta^i, \omega_j^i, \Omega_j^i$ on $O(TM)$. For another Riemannian manifold $(N^m, \langle \cdot, \cdot \rangle)$ we have, similarly, $\mathfrak{o}(m)$ -valued forms $\phi^\alpha, \psi_\beta^\alpha, \Psi_\beta^\alpha$ on $O(TN)$.

Now suppose that we are given a Riemannian manifold $(M^n, \langle \cdot, \cdot \rangle)$, and an $(m - n)$ -dimensional vector bundle $\varpi: E \rightarrow M$ with a Riemannian metric $\{ \cdot, \cdot \}$. Let $O(TM, E)$ denote the set of all pairs (u, v) where $u \in O(TM)$ and $v \in O(E)$ lie over the same point $p \in M$. Then $O(TM, E)$ is a principal bundle, whose group G is the set of all $m \times m$ matrices of the form

$$\begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix} \quad A \in O(n) \quad \text{and} \quad B \in O(m - n).$$

These bundles will come into our proof of the generalization of Theorem 19 in the following way. If we succeed in finding an isometric immersion $f: M \rightarrow N$, covered by an inner product preserving bundle isomorphism $\tilde{f}: E \rightarrow \{\text{normal bundle of } f(M)\}$, then we will also have a “principal bundle isomorphism” from $O(TM, E)$ into $O(TM)|f(M)$. Instead of looking for f directly, we will look for this principal bundle isomorphism. Since the graph of this principal bundle isomorphism is a subset of $O(TM, E) \times O(TN)$, we will look for the graph as an integral submanifold of a certain distribution on $O(TM, E) \times O(TN)$; if $(u, v) \in O(TM, E)$ and $w \in O(TN)$, then the integral manifold through $((u, v), w)$ will turn out to be the graph of the principal bundle isomorphism determined by (f_*, \tilde{f}) , where $f: M \rightarrow N$ is an isometry with $f_*(u_i) = w_i$, and $\tilde{f}(v_r) = w_r$. Thus, although our set-up is now rather complicated, it is very natural to look for maps from $O(TM, E)$ to $O(TN)$, because they involve precisely the right amount of leeway which we expect in the choice of the isometric imbedding $f: M \rightarrow N$.

20. THEOREM. The results of Theorem 19 hold when \mathbb{R}^m is replaced by a complete connected Riemannian manifold $(N, \langle \cdot, \cdot \rangle)$ of constant curvature K_0 , and the following modifications are made:

- (1) The map A in the conclusion of part (1) is replaced by an isometry $A: N \rightarrow N$.

(2) Gauss' Equation in the hypothesis of part (2) is stated as:

$$\begin{aligned} K_0[\langle\langle X, W \rangle\rangle \langle\langle Y, Z \rangle\rangle - \langle\langle X, Z \rangle\rangle \langle\langle Y, W \rangle\rangle] \\ = \langle\langle R(X, Y)Z, W \rangle\rangle + \{\sigma(X, Z), \sigma(Y, W)\} - \{\sigma(Y, Z), \sigma(X, W)\}. \end{aligned}$$

PROOF. Again we will begin by considering the second part of the theorem. So we are given $(M, \langle\langle \cdot, \cdot \rangle\rangle)$ and the bundle $\varpi: E \rightarrow M$, with metric $\{ \cdot, \cdot \}$, a connection δ compatible with $\{ \cdot, \cdot \}$, and a symmetric section σ of the bundle $\text{Hom}(TM \times TM, E)$. Then δ gives us a connection form $\bar{\Psi}$ on $O(E)$ which is $\mathfrak{o}(m-n)$ -valued; we will denote its components by $\bar{\Psi}_s^r$ for $r, s = n+1, \dots, m$. Similarly, $(\bar{\Psi}_s^r)$ will be the curvature form on $O(E)$.

Now we have obvious maps

$$\begin{array}{ccc} & O(TM, E) & \\ \lambda_1 \swarrow & & \searrow \lambda_2 \\ O(TM) & & O(E). \end{array}$$

For convenience we will denote

$$\begin{array}{ll} \lambda_1^*(\theta^i), \lambda_1^*(\omega_j^i), \lambda_1^*(\Omega_j^i) & \text{simply by } \theta^i, \omega_j^i, \Omega_j^i \\ \lambda_2^*(\bar{\Psi}_s^r), \lambda_2^*(\bar{\Psi}_s^r) & \text{simply by } \bar{\Psi}_s^r, \bar{\Psi}_s^r. \end{array}$$

We define functions $s_{ij}^r: O(TM, E) \rightarrow \mathbb{R}$ as follows. An element of $O(TM, E)$ is a pair (u, v) , where u and v are orthonormal frames, of TM and E , respectively, at the same point p . Then $\sigma(u_i, u_j)$ can be written uniquely as

$$\sigma(u_i, u_j) = \sum_r s_{ij}^r ((u, v)) \cdot v_r.$$

We now define forms $\bar{\Psi}_i^r$ directly on $O(TM, E)$ by

$$\bar{\Psi}_i^r = \sum_j s_{ij}^r \theta^j \quad \left(= \sum_j s_{ij}^r \lambda_1^*(\theta^j) \right).$$

The symmetry of σ implies that $s_{ij}^r = s_{ji}^r$, and thus that

$$(1) \quad \sum_i \bar{\Psi}_i^r \wedge \theta^i = 0.$$

Now we claim that on the bundle $O(TM, E)$ we have

$$(2) \quad K_0[\theta^i \wedge \theta^j] = \Omega_j^i - \sum_r \bar{\Psi}_i^r \wedge \bar{\Psi}_j^r$$

$$(3) \quad d\bar{\Psi}_j^r = - \sum_i \bar{\Psi}_i^r \wedge \omega_j^i - \sum_s \bar{\Psi}_s^r \wedge \bar{\Psi}_j^s$$

$$(4) \quad d\bar{\Psi}_s^r = \sum_i \bar{\Psi}_i^r \wedge \bar{\Psi}_i^s - \sum_w \bar{\Psi}_w^r \wedge \bar{\Psi}_s^w.$$

The proof is in two steps. First, consider a local section $(X_1, \dots, X_n, \nu_{n+1}, \dots, \nu_m) = \xi: U \rightarrow O(TM, E)$ on $U \subset M$. Denote $\xi^*(\theta^i)$ by θ^i , etc., and $\xi^*(\bar{\Psi}_i^r)$ by $\bar{\Psi}_i^r$. Then the θ^i , ω_j^i , and Ω_j^i are the forms for the moving frame X_1, \dots, X_n . When we apply ξ^* to equations (2)–(4), we obtain equations on M , of which the first, for example, reads

$$(2') \quad K_0[\theta^i \wedge \theta^j] = \Omega_j^i - \sum_r \bar{\Psi}_i^r \wedge \bar{\Psi}_j^r.$$

When we take into account the fact that

$$\bar{\Psi}_i^r = \xi^* \bar{\Psi}_i^r = \sum_k (s_{ik}^r \circ \xi) \cdot \xi^* \theta^k = \sum_k \langle \sigma(X_i, X_k), \nu_r \rangle \theta^k,$$

we find, by a straightforward calculation, that equation (2') is equivalent to Gauss' equation. As in the proof of Theorem 18, we can even avoid the calculation by realizing that it will be essentially the same as the calculation which shows that equation (A') is equivalent to Gauss' equation. In a similar manner, we see that true equations result from applying ξ^* to (3) and (4). This means that equations (2)–(4) hold when applied to tangent vectors which are not vertical. So we just have to prove that (2)–(4) hold when applied to a pair of vectors of which at least one is vertical.

The 1-forms θ^i on $O(TM)$ are zero on any vertical vector, while the 2-forms Ω_j^i are zero on any pair of vectors of which at least one is vertical. Since the vertical vectors of $O(TM, E)$ are precisely the vectors Y for which $\lambda_{1*}(Y)$ is vertical in $O(TM)$ and $\lambda_{2*}(Y)$ is vertical in $O(E)$, we see that the forms θ^i and Ω_j^i on $O(TM, E)$ have the same property as the forms θ^i and Ω_j^i on $O(TM)$. Analogous statements hold for the forms Ψ_s^r on $O(TM, E)$. Moreover, the forms $\bar{\Psi}_i^r$ are clearly 0 on vertical vectors of $O(TM, E)$. It is thus clear that (2) holds when applied to a pair of vectors one of which is vertical. To treat equation (4), we note that the structural equation for $O(E)$ gives

$$d\bar{\Psi}_s^r = - \sum_w \bar{\Psi}_w^r \wedge \bar{\Psi}_s^w + \bar{\Psi}_s^r.$$

Since $\bar{\Psi}_s^r$ is zero on a pair of vectors one of which is vertical, while Ψ_i^r and Ψ_i^s are zero on vertical vectors, this clearly gives the result for equation (4). Thus we are left with equation (3). If *both* our vectors Y_1, Y_2 are vertical, then the right side of (3) is zero; on the other hand, if \tilde{Y}_1, \tilde{Y}_2 are vertical vector fields extending Y_1, Y_2 , then the left side is

$$\begin{aligned} d\bar{\Psi}_j^r(Y_1, Y_2) &= Y_1(\bar{\Psi}_j^r(\tilde{Y}_2)) - Y_2(\bar{\Psi}_j^r(\tilde{Y}_1)) - \bar{\Psi}_j^r([\tilde{Y}_1, \tilde{Y}_2]) \\ &= 0, \end{aligned}$$

since $\bar{\Psi}_j^r$ is zero on vertical vectors. This leaves us with equation (3) in the case where just one vector is vertical.

Every vertical vector at a frame (u, v) at p is $\sigma(\Gamma)(u, v)$ for some Γ in the Lie algebra \mathfrak{g} of the group G of $O(TM, E)$. We want to show that (3) holds when applied to

$$Y_1 = \sigma(\Gamma)(u, v), \quad Y_2 = \xi_*(X_p),$$

for some $X_p \in M_p$ and some local section $(X_1, \dots, X_n, v_{n+1}, \dots, v_m) = \xi: U \rightarrow O(TM, E)$. We extend Y_2 to a vector field \tilde{Y}_2 as follows. First extend X_p to a vector field X on M . Then $\xi_*(X)$ is a vector field defined at just one point in each fibre. We extend $\xi_*(X)$ to \tilde{Y}_2 by making it invariant under R_{a*} for all $a \in G$. This means, in particular, that for the Lie derivative we have

$$0 = L_{\sigma(\Gamma)}\tilde{Y}_2 = [\sigma(\Gamma), \tilde{Y}_2].$$

Equation (3), applied to Y_1, Y_2 thus becomes

$$(3') \quad Y_1(\bar{\Psi}_j^r(\tilde{Y}_2)) = \sum_i \bar{\Psi}_i^r(Y_2)\omega_j^i(Y_1) - \sum_s \bar{\Psi}_s^r(Y_1)\bar{\Psi}_j^s(Y_2).$$

To prove equation (3'), we need information about $R_a^*\bar{\Psi}_j^r$, for $a \in G$. We write a as

$$a = \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix} \quad A \in O(n), \quad B \in O(m-n).$$

Let us note first that the definition of s_{ij}^r gives

$$\sigma((u \cdot A)_i, (u \cdot A)_j) = \sum_r s_{ij}^r((u, v) \cdot a) \cdot (v \cdot B)_r.$$

From this we easily find that

$$s_{ij}^r((u, v) \cdot a) = \sum_{k,l=1}^n \sum_{\rho=n+1}^m A_i^k A_j^l s_{kl}^\rho(u, v) (B^{-1})_\rho^r.$$

We can now compute

$$R_a^* \bar{\Psi}_i^r = \sum_j (s_{ij}^r \circ R_a) \cdot R_a^* \theta^i,$$

using the equation (Proposition II.8-12)

$$R_A^* \theta^i = \sum_k (A^{-1})_k^i \theta^k;$$

we find that the $(m - n) \times n$ matrix $[\bar{\Psi}] = (\bar{\Psi}_i^r)$ satisfies

$$(*) \quad R_a^* [\bar{\Psi}] = B^{-1} [\bar{\Psi}] A.$$

Now suppose we write $\Gamma \in \mathfrak{g}$ as

$$\Gamma = \begin{pmatrix} \Gamma_1 & 0 \\ 0 & \Gamma_2 \end{pmatrix} \quad \text{for } \Gamma_1 \in \mathfrak{o}(n), \quad \Gamma_2 \in \mathfrak{o}(m - n).$$

An integral curve of $Y_1 = \sigma(\Gamma)(u, v)$ is given by

$$t \mapsto (u, v) \cdot \exp t\Gamma = R_{\exp t\Gamma}(u, v).$$

So for the left side of (3') we find that

$$\begin{aligned} Y_1(\bar{\Psi}_j^r(\tilde{Y}_2)) &= \lim_{h \rightarrow 0} \frac{1}{h} [\bar{\Psi}_j^r(\tilde{Y}_2(R_{\exp h\Gamma}(u, v))) - \bar{\Psi}_j^r(Y_2)] \\ &= \lim_{h \rightarrow 0} \frac{1}{h} [\bar{\Psi}_j^r(R_{\exp h\Gamma} Y_2) - \bar{\Psi}_j^r(Y_2)] \\ &\quad \text{(from the way } \tilde{Y}_2 \text{ was defined)} \\ &= \lim_{h \rightarrow 0} \frac{1}{h} [((R_{\exp h\Gamma})^* \bar{\Psi}_j^r)(Y_2) - \bar{\Psi}_j^r(Y_2)] \\ &= ({}_j^r) \text{ component of} \\ &\quad \lim_{h \rightarrow 0} \frac{1}{h} [(\{\exp h\Gamma_2\}^{-1} \cdot [\bar{\Psi}] \cdot \exp h\Gamma_1)(Y_2) - [\bar{\Psi}](Y_2)] \\ &\quad \text{by equation } (*) \\ &= ({}_j^r) \text{ component of } \{-\Gamma_2 \cdot [\bar{\Psi}(Y_2)] + [\bar{\Psi}(Y_2)]\Gamma_1\} \\ &= -\sum_s (\Gamma_2)_s^r \bar{\Psi}_j^s(Y_2) + \sum_i \bar{\Psi}_i^r(Y_2) \cdot (\Gamma_1)_j^i \\ &= -\sum_s \bar{\Psi}_s^r(\sigma(\Gamma)) \bar{\Psi}_j^s(Y_2) + \sum_i \bar{\Psi}_i^r(Y_2) \omega_j^i(\sigma(\Gamma_1)) \\ &= -\sum_s \bar{\Psi}_s^r(Y_1) \bar{\Psi}_j^s(Y_2) + \sum_i \bar{\Psi}_i^r(Y_2) \omega_j^i(Y_1), \end{aligned}$$

which is precisely the right side of (3').

After all this work, we are ready to construct a distribution on the product $O(TM, E) \times O(TN)$. We introduce the two projections

$$\begin{array}{ccc} O(TM, E) \times O(TN) & \xrightarrow{\pi_2} & O(TN) \\ \downarrow \pi_1 & & \\ O(TM, E) & & \end{array}$$

Define $\Delta_{((u,v),w)}$ to be the set of all tangent vectors at $((u,v),w)$ on which the following 1-forms all vanish:

- (a) $\pi_2^* \phi^i - \pi_1^* \theta^i$
- (b) $\pi_2^* \phi^r$
- (c) $\pi_2^* \psi_j^i - \pi_1^* \omega_j^i$
- (d) $\pi_2^* \psi_s^r - \pi_1^* \bar{\psi}_s^r$
- (e) $\pi_2^* \bar{\psi}_j^r - \pi_1^* \bar{\psi}_j^r.$

Since the forms $\phi^\alpha, \psi_\beta^\alpha$ ($\alpha < \beta$) are a basis for the dual space of the tangent space $O(TN)_w$, it is clear that each $\Delta_{((u,v),w)}$ has dimension

$$\dim O(TM, E) \times O(TN) - \dim O(TN) = \dim O(TM, E),$$

and that $\pi_{1*}: \Delta_{((u,v),w)} \rightarrow O(TM, E)_{(u,v)}$ is an isomorphism. We thus obtain a distribution Δ .

For any $a \in G$, we have the map $R_a: O(TM, E) \rightarrow O(TM, E)$. Since $a \in G \subset O(m) = \text{group of the bundle } O(TN)$, we also have maps, which we will denote by the same letter, $R_a: O(TN) \rightarrow O(TN)$. These maps then give us maps

$$R_a: O(TM, E) \times O(TN) \rightarrow O(TM, E) \times O(TN).$$

We claim that $R_{a*} \Delta = \Delta$. To prove this, it suffices to show that $R_a^* \eta$ is a linear combination of the forms (a)–(e) whenever η is any of the forms in (a)–(e). If

$$a = \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix},$$

then Proposition II.8-12 shows that the \mathbb{R}^m -valued form $\pi_2^* \phi$ satisfies

$$R_a^* \pi_2^* \phi = \pi_2^* R_a^* \phi = \pi_2^* a^{-1} \phi = \pi_2^* \begin{pmatrix} A^{-1} & 0 \\ 0 & B^{-1} \end{pmatrix} \phi,$$

while

$$R_a^* \pi_1^* \theta = \pi_1^* R_a^* \theta = \pi_1^* A^{-1} \theta.$$

From this we see that $R_a^* \eta$ has the required property when η is one of the forms in (a) or (b). We also have, by Proposition II.8-11,

$$R_a^* \pi_2^* \psi = \pi_2^* R_a^* \psi = \pi_2^* a^{-1} \psi a = \pi_2^* \begin{pmatrix} A^{-1} & 0 \\ 0 & B^{-1} \end{pmatrix} \psi \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix};$$

for the same reason we have

$$\begin{aligned} R_a^* \pi_1^* \omega &= \pi_1^* A^{-1} \omega A, \\ R_a^* \pi_1^* \bar{\psi} &= \pi_1^* B^{-1} \bar{\psi} B, \quad \bar{\psi} = (\bar{\psi}_s^r), \end{aligned}$$

while (*) gives

$$R_a^* \pi_1^* [\bar{\psi}] = \pi_1^* B^{-1} [\bar{\psi}] A \quad [\bar{\psi}] = (\bar{\psi}_i^r).$$

From these equations we see that $R_a^* \eta$ has the required property when η is one of the forms in (c)–(e).

Now we claim that our distribution Δ is *integrable*. According to Proposition I.7-14, we just have to show that the differentials of all the forms in (a)–(e) are in the ideal \mathcal{I} generated by these forms. Now we have, for example,

$$\begin{aligned} d(\pi_2^* \phi^i - \pi_1^* \theta^i) &= \pi_2^* \left(- \sum_j \psi_j^i \wedge \phi^j \right) - \pi_1^* \left(- \sum_j \omega_j^i \wedge \theta^j \right) \\ &\quad + \pi_2^* \left(- \sum_r \psi_r^i \wedge \phi^r \right). \end{aligned}$$

The last term is in \mathcal{I} , since the forms (b) are. The first two terms can be written

$$- \sum_j \pi_2^* \psi_j^i \wedge (\pi_2^* \phi^j - \pi_1^* \theta^j) - \sum_j (\pi_2^* \psi_j^i - \pi_1^* \omega_j^i) \wedge \pi_1^* \theta^j,$$

which is in \mathcal{I} . For the exterior differential

$$d(\pi_2^* \phi^r) = \pi_2^* \left(- \sum_i \psi_i^r \wedge \phi^i \right) + \pi_2^* \left(- \sum_s \psi_s^r \wedge \phi^s \right).$$

we note that the second term is in \mathcal{I} , while the first can be written

$$\begin{aligned} - \sum_i (\pi_2^* \psi_i^r - \pi_1^* \bar{\psi}_i^r) \wedge \pi_2^* \phi^i - \sum_i \pi_1^* \bar{\psi}_i^r \wedge (\pi_2^* \phi^i - \pi_1^* \theta^i) \\ - \sum_i \pi_1^* (\bar{\psi}_i^r \wedge \theta^i); \end{aligned}$$

the first two terms are in \mathcal{I} , while the third is zero by equation (1). We will briefly outline the check for (c), and leave the others for the reader. We have

$$\begin{aligned} d(\pi_2^* \psi_j^i - \pi_1^* \omega_j^i) &= \pi_2^* \left(- \sum_k \psi_k^i \wedge \psi_j^k \right) - \pi_1^* \left(- \sum_k \omega_k^i \wedge \omega_j^k \right) \\ &\quad + \pi_2^* \left(- \sum_r \psi_r^i \wedge \psi_j^r \right) + \pi_2^*(\Psi_j^i) - \pi_1^*(\Omega_j^i). \end{aligned}$$

Since N has constant curvature K_0 , we have $\pi_2^*(\Psi_j^i) = K_0 \pi_2^*(\phi^i \wedge \phi^j)$, while equation (2) tells us how to get rid of $\pi_1^*(\Omega_j^i)$. We obtain, in particular, the term

$$\begin{aligned} K_0[\pi_2^* \phi^i \wedge \pi_2^* \phi^j - \pi_1^* \theta^i \wedge \pi_1^* \theta^j] \\ = K_0[(\pi_2^* \phi^i - \pi_1^* \theta^i) \wedge \pi_2^* \phi^j \\ + \pi_1^* \theta^i \wedge (\pi_2^* \phi^j - \pi_1^* \theta^j)], \end{aligned}$$

which is in \mathcal{I} . The other terms are easily paired off and treated as above.

Now consider an integral manifold Γ of the distribution Δ . Since the map $\pi_{1*}: \Delta_{((u,v),w)} \rightarrow O(TM, E)_{(u,v)}$ is always an isomorphism, the map $\pi_1: \Gamma \rightarrow O(TM, E)$ is a diffeomorphism in a neighborhood of any point. Replacing M by a sufficiently small open subset of M if necessary, we may assume that $\pi_1: \Gamma \rightarrow O(TM, E)$ is a diffeomorphism. Then Γ is the graph of a function $g: O(TM, E) \rightarrow O(TN)$, given explicitly by

$$g = \pi_2 \circ (\pi_1|_{\Gamma})^{-1}.$$

Because $R_{a*}\Delta = \Delta$ for all $a \in G$, it is easy to see that g takes fibres of $O(TM, E)$ to fibres of $O(TN)$, so that there is a diffeomorphism $f: M \rightarrow N$ for which the following diagram commutes.

$$\begin{array}{ccc} O(TM, E) & \xrightarrow{g} & O(TN) \\ \pi \downarrow & & \downarrow \pi_N \\ M & \xrightarrow{f} & N \end{array}$$

Now suppose we have a tangent vector $X_p \in M_p$, a frame $(u, v) \in \pi^{-1}(p)$, and a tangent vector $Y \in O(TM, E)_{(u,v)}$ with $\pi_* Y = X_p$. Then, by definition of θ^i , we have

$$\theta^i(Y) = i^{\text{th}} \text{ component of } X_p \text{ with respect to the frame } u.$$

Now

$$f_*X_p = f_*\pi_*Y = \pi_{N*}g_*Y,$$

so we likewise have

$$\begin{aligned} & i^{\text{th}} \text{ component of } f_*X_p \text{ with respect to the frame } g((u, v)) \\ &= \phi^i(g_*Y) \\ &= \phi^i(\pi_{2*}(\pi_1|\Gamma)^{-1}_*(Y)) \\ &= \pi_{2*}\phi^i((\pi_1|\Gamma)^{-1}_*(Y)) \\ &= \pi_{1*}\theta^i((\pi_1|\Gamma)^{-1}_*(Y)) \quad \text{since the forms (a) are zero on } \Gamma \\ &= \theta^i(Y). \end{aligned}$$

Similarly, since the forms (b) vanish on Γ , we find that

$$r^{\text{th}} \text{ component of } f_*X_p \text{ with respect to the frame } g((u, v)) = 0.$$

This shows us that g is of the form

$$g((u, v)) = (f_*(u), \tilde{f}(v)),$$

for some bundle isomorphism $\tilde{f}: E \rightarrow \{\text{normal bundle of } f(M) \text{ in } N\}$ covering f . The map f is an isometry, since f_* takes orthonormal frames to orthonormal frames, and the map \tilde{f} is inner product preserving, for the same reason.

The proof that \tilde{f} makes σ correspond to s and δ correspond to D is similar to the above arguments, using the fact that the forms (c)–(e) vanish on Γ .

We have thus proved the existence part of the theorem locally. Simple-connectivity is then used to prove the global result, in the standard way. The uniqueness part of the theorem is handled just like the uniqueness part of Theorem 18. ♦

For ease of reference, we want to have an explicit statement of Theorem 20 in the case of hypersurfaces. We will assume that the ambient space N is orientable. In this case we claim that a diffeomorphism $\phi: M \rightarrow \bar{M}$ between immersed hypersurfaces is always covered by an inner product preserving bundle isomorphism $\tilde{\phi}: \text{Nor } M \rightarrow \text{Nor } \bar{M}$. To construct $\tilde{\phi}$ we first choose a particular orientation for N . Then for $p \in M$ we choose an ordered basis $X_1, \dots, X_n \in M_p$ and a unit normal $v_p \in M_p^\perp$ such that (X_1, \dots, X_n, v_p) is positively oriented in N_p . Then there is a unique unit normal $\bar{v}_{\phi(p)} = M_{\phi(p)}^\perp$ such that $(\phi_*X_1, \dots, \phi_*X_n, \bar{v}_{\phi(p)})$ is positively oriented in $N_{\phi(p)}$. We let $\tilde{\phi}: M_p^\perp \rightarrow \bar{M}_{\phi(p)}^\perp$ be the linear map taking v_p to $\bar{v}_{\phi(p)}$; it is clear that this map is well-defined. If $-1: \text{Nor } M \rightarrow \text{Nor } M$ is the bundle equivalence taking $X \in M_p^\perp$

to $-X \in M_p^\perp$, then $\tilde{\bar{\phi}} = \tilde{\phi} \circ -1$: $\text{Nor } M \rightarrow \text{Nor } \bar{M}$ is another inner product preserving bundle isomorphism covering ϕ , and these are clearly the only such. When N is oriented, the hypersurfaces M, \bar{M} are also oriented, and $\phi: M \rightarrow \bar{M}$ is orientation preserving, things are even simpler, for there are unit normal fields ν and $\bar{\nu}$ on M and \bar{M} , determined by their orientations (and the orientation of N), and the obvious $\tilde{\phi}$ to consider is the one taking ν to $\bar{\nu}$.

21. THEOREM. Let $(N^{n+1}, \langle \cdot, \cdot \rangle)$ be an orientable complete connected Riemannian manifold of constant curvature K_0 .

(1) Let M and \bar{M} be connected hypersurfaces of N , let $\phi: M \rightarrow \bar{M}$ be an isometry, and let $\tilde{\phi}: \text{Nor } M \rightarrow \text{Nor } \bar{M}$ be one of the two inner product preserving bundle isomorphisms covering ϕ . Suppose that either

$$\bar{s}(\phi_* X, \phi_* Y) = \tilde{\phi}(s(X, Y))$$

for all tangent vectors X, Y at all points of M , or

$$\bar{s}(\phi_* X, \phi_* Y) = -\tilde{\phi}(s(X, Y))$$

for all X, Y . Then ϕ is the restriction of an isometry $A: N \rightarrow N$ with $A_* = \tilde{\phi}$ or $A_* = -\tilde{\phi}$ on $\text{Nor } M$.

(1') Choose an orientation for N , and let M and \bar{M} be connected oriented hypersurfaces of N , with unit normal fields ν and $\bar{\nu}$ determined by their orientations (and the orientation of N), with corresponding second fundamental forms II and $\bar{\text{II}}$. Suppose that $\phi: M \rightarrow \bar{M}$ is an orientation preserving isometry with $\phi^* \bar{\text{II}} = \text{II}$. Then ϕ is the restriction of an orientation preserving isometry $A: N \rightarrow N$ with $A_* \nu = \bar{\nu}$.

(2) Let $(M, \langle \cdot, \cdot \rangle)$ be a simply-connected n -dimensional Riemannian manifold, with covariant differentiation ∇ and curvature tensor R , and let S be a symmetric tensor on M , covariant of order 2. Suppose that S satisfies

(1) Gauss' Equation:

$$\begin{aligned} K_0[\langle X, W \rangle \cdot \langle Y, Z \rangle - \langle X, Z \rangle \cdot \langle Y, W \rangle] \\ = \langle R(X, Y)Z, W \rangle + S(X, Z) \cdot S(Y, W) - S(Y, Z) \cdot S(X, W) \end{aligned}$$

(2) The Codazzi-Mainardi Equations:

$$(\nabla_X S)(Y, Z) = (\nabla_Y S)(X, Z).$$

Then there is an isometric immersion $f: M \rightarrow N$ such that $S = f^* \text{II}$, where II is the second fundamental form on $f(M)$ for some unit normal field ν .

One concluding remark is in order. In Chapter 2 we showed that the Gauss and Codazzi-Mainardi equations for a surface in \mathbb{R}^3 are equivalent to the equations of structure of $O(3)$, and that the Fundamental Theorem of Surface Theory reduces to Theorems I.10-17 and I.10-18 about Lie groups. It is not hard (Problem 15) to show, similarly, that the Gauss, Codazzi-Mainardi, and Ricci equations for a submanifold of \mathbb{R}^m are equivalent to the equations of structure of $O(m)$, and that Theorem 19 reduces to theorems about Lie groups. The Lie group $O(m)$ makes its appearance here because of the fact that the group of Euclidean motions of \mathbb{R}^m is a semi-direct product $\mathbb{R}^m \times O(m)$. For a general Riemannian manifold $(N, \langle \cdot, \cdot \rangle)$ of constant curvature K_0 , the group of isometries cannot be factored in this way. That is why our proof of Theorem 20 involved the bundle $O(N)$ of orthonormal frames of N . As a matter of fact, the bundle $O(N)$ is the group of isometries of N (as a set), since an isometry is determined by knowing which orthonormal frame $u \in O(N)$ is the image of some fixed orthonormal frame u_0 . Thus we ought to be able to interpret the Gauss, Codazzi-Mainardi, and Ricci equations for a submanifold of N as the equations of structure of $O(N)$, equipped with the appropriate group structure, and Theorem 20 should reduce to Theorems I.10-17 and I.10-18. However, we forbear to enter any further into such considerations.

D. FIRST CONSEQUENCES

We begin by considering hypersurfaces $M^n \subset \mathbb{R}^{n+1}$. In a neighborhood of any point of M there is a unit normal field $v: M^n \rightarrow S^n \subset \mathbb{R}^{n+1}$, unique up to sign, and hence a single second fundamental form $\Pi: M_p \times M_p \rightarrow \mathbb{R}$ (which is defined only up to sign). We also have the map $dv: M_p \rightarrow M_p$ with

$$\begin{aligned} \Pi(X_p, Y_p) &= \langle s(X_p, Y_p), v(p) \rangle \\ &= \langle \nabla'_{X_p} Y, v(p) \rangle \\ &= -\langle \nabla'_{X_p} v, Y_p \rangle \\ &= \langle -dv(X_p), Y_p \rangle. \end{aligned}$$

Thus $-dv: M_p \rightarrow M_p$ is a symmetric linear transformation. As in Chapter 2, we define the **principal directions** at p to be the unit eigenvectors $X_p \in M_p$ for $-dv: M_p \rightarrow M_p$, and we define the **principal curvatures** to be the corresponding eigenvalues. Equivalently, the principal curvatures are the eigenvalues of the symmetric matrix $(\Pi(X_i, X_j)) = (\langle s(X_i, X_j), v(p) \rangle)$ for X_1, \dots, X_n an orthonormal basis of M_p .

Various kinds of curvatures can be defined in terms of the k_i . Since the ordering of the k_i is arbitrary, we obviously want to consider only combinations

of the k_i which are invariant under all permutations of the indices $1, \dots, n$. It is well-known that any polynomial function of n variables t_1, \dots, t_n which is invariant under all permutations of $1, \dots, n$ can be written as a polynomial in the “elementary symmetric functions” $\sigma_1, \dots, \sigma_n$ defined by

$$\begin{aligned}\sigma_1(t_1, \dots, t_n) &= \sum_{i=1}^n t_i, & \sigma_2(t_1, \dots, t_n) &= \sum_{i < j} t_i t_j, \\ \sigma_3(t_1, \dots, t_n) &= \sum_{i < j < k} t_i t_j t_k & \dots & \\ \sigma_n(t_1, \dots, t_n) &= t_1 t_2 \cdots t_n.\end{aligned}$$

These functions are the coefficients, up to sign, of the various powers of x in the polynomial

$$\begin{aligned}P_{t_1, \dots, t_n}(x) &= (x - t_1)(x - t_2) \cdots (x - t_n) \\ &= x^n - \sigma_1(t_1, \dots, t_n)x^{n-1} + \cdots + (-1)^n \sigma_n(t_1, \dots, t_n).\end{aligned}$$

[Recall also that if $\sigma_i(t_1, \dots, t_n) = \sigma_i(u_1, \dots, u_n)$ for all i , then the polynomials $P_{t_1, \dots, t_n}(x)$ and $P_{u_1, \dots, u_n}(x)$ are equal, and thus the set of their roots, $\{t_1, \dots, t_n\}$ and $\{u_1, \dots, u_n\}$, are also equal, counting multiplicities.] We define the **(elementary symmetric) curvatures** $K_1(p), \dots, K_n(p)$ by

$$\binom{n}{j} K_j(p) = \sigma_j(k_1, \dots, k_n),$$

where the k_i are the principal curvatures at p ; the binomial coefficient $\binom{n}{j}$ is inserted for sentimental reasons. In particular,

$$H(p) = K_1(p) = \frac{k_1 + \cdots + k_n}{n} \quad \text{is called the **mean curvature**,}$$

$$K(p) = K_n(p) = k_1 \cdots k_n \quad \text{is called the **Gaussian curvature**.}$$

Notice that $K_j(p)$ is independent of the choice of v for j even, while $K_j(p)$ is only defined up to sign for j odd.

In the case of surfaces, we found that the Gaussian curvature $K = k_1 \cdot k_2$ is an invariant under isometry. In general, we have

22. PROPOSITION. For hypersurfaces of \mathbb{R}^{n+1} , the set of the $\binom{n}{2}$ numbers $\{k_i k_j : i < j\}$ is invariant under isometry: If $f: M \rightarrow \bar{M}$ is an isometry between two hypersurfaces $M, \bar{M} \subset \mathbb{R}^{n+1}$, and k_1, \dots, k_n are the principal curvatures of M at p , while $\bar{k}_1, \dots, \bar{k}_n$ are the principal curvatures of \bar{M} at $f(p)$, then the sets $\{k_i k_j : i < j\}$ and $\{\bar{k}_i \bar{k}_j : i < j\}$ are equal, counting multiplicities.

PROOF. For $X, Y \in M_p$, let $\tilde{R}(X, Y)$ denote the map $M_p \times M_p \rightarrow \mathbb{R}$ defined by

$$\tilde{R}(X, Y)(Z, W) = \langle R(X, Y)Z, W \rangle.$$

The symmetry properties of R show that the map $\tilde{R}(X, Y)$ is skew-symmetric, so that $\tilde{R}(X, Y) \in \Omega^2(M_p)$. Now the inner product $\langle \cdot, \cdot \rangle_p$ on M_p gives us a map $X \mapsto X^*$ from M_p to M_p^* , defined by $X^*(Y) = \langle X, Y \rangle$. Choose a basis X_1, \dots, X_n for M_p and consider the map from $\Omega^2(M_p)$ to $\Omega^2(M_p)$ given by

$$X_i^* \wedge X_j^* \mapsto \tilde{R}(X_i, X_j);$$

this makes sense since the $X_i^* \wedge X_j^*$ for $i < j$ are a basis for $\Omega^2(M_p)$ and since $\tilde{R}(X_j, X_i) = -\tilde{R}(X_i, X_j)$. We see immediately that under this map

$$(\sum_i a_i X_i)^* \wedge (\sum_j b_j X_j)^* \mapsto \tilde{R}(\sum_i a_i X_i, \sum_j b_j X_j),$$

so we can describe our map, without any choice of basis, as

$$(1) \quad X^* \wedge Y^* \mapsto \tilde{R}(X, Y), \quad \text{from } \Omega^2(M_p) \text{ to } \Omega^2(M_p).$$

Now the vector space $\Omega^2(M_p)$ has dimension $\binom{n}{2}$, so this map has $\binom{n}{2}$ eigenvalues (counting multiplicities). But if X_1, \dots, X_n are principal vectors at p , with corresponding eigenvalues k_1, \dots, k_n , then Gauss' equation tells us that

$$\tilde{R}(X_i, X_j) = -k_i k_j X_i^* \wedge X_j^*.$$

So the set $\{-k_i k_j : i < j\}$ is the set of eigenvalues of the map (1). Since (1) is defined in terms of the curvature tensor R and the metric $\langle \cdot, \cdot \rangle$, this proves that $\{-k_i k_j : i < j\}$ is invariant under isometry. ♦

23. COROLLARY (THEOREMA EGREGIUM). For hypersurfaces in \mathbb{R}^{n+1} , the Gaussian curvature K is invariant under isometry if n is even, and invariant up to sign if n is odd.

PROOF. Observe that

$$K^{n-1} = \left(\prod_{i=1}^n k_i \right)^{n-1} = \prod_{i < j} k_i k_j. \quad \blacklozenge$$

There is another way of reaching this result, which will provide us with an explicit formula for K in terms of R and $\langle \ , \ \rangle$, a formula which will be extremely important in Chapter 13. First we will do a little linear algebra. Let V be a vector space of *even* dimension n , and let $f: V \rightarrow V$ be a linear transformation having matrix $A = (a_{ij})$ with respect to a basis v_1, \dots, v_n . We propose to find $\det f = \det A$ in terms of the determinants of all 2×2 submatrices of A . We will let

$$D(i_1, i_2; j_1, j_2) = a_{i_1 j_1} a_{i_2 j_2} - a_{i_1 j_2} a_{i_2 j_1},$$

so that if $i_1 < i_2$ and $j_1 < j_2$, then $D(i_1, i_2; j_1, j_2)$ is the determinant of the 2×2 submatrix of A obtained by selecting rows i_1 and i_2 , and columns j_1 and j_2 . Recall that $\det f$ can be defined as follows. The linear transformation f gives us a map $f^*: \Omega^k(V) \rightarrow \Omega^k(V)$ defined by

$$f^*(T)(v_1, \dots, v_k) = T(f(v_1), \dots, f(v_k)), \quad \text{all } T \in \Omega^k(V).$$

In particular, we have the map $f^*: \Omega^n(V) \rightarrow \Omega^n(V)$. Since $\Omega^n(V)$ is 1-dimensional, this map must be multiplication by a constant; and this constant is, in fact, just $\det f$. Now our map f^* also satisfies

$$f^*(\phi_1 \wedge \dots \wedge \phi_k) = f^*(\phi_1) \wedge \dots \wedge f^*(\phi_k) \quad \text{all } \phi_i \in \Omega^1(V).$$

In particular, let the ϕ_i be the dual basis to the v_i . Then

$$f(v_i) = \sum_{j=1}^n a_{ji} v_j \implies f^*(\phi_i) = \sum_{j=1}^n a_{ij} \phi_j.$$

So

$$\begin{aligned} f^*(\phi_1 \wedge \dots \wedge \phi_n) &= [f^*(\phi_1) \wedge f^*(\phi_2)] \wedge \dots \\ &= \left(\sum_{j=1}^n a_{1j} \phi_j \wedge \sum_{k=1}^n a_{2k} \phi_k \right) \wedge \dots \\ &= \left(\sum_{j < k} [a_{1j} a_{2k} - a_{1k} a_{2j}] \phi_j \wedge \phi_k \right) \wedge \dots \\ &= \left(\frac{1}{2} \sum_{j, k} D(1, 2; j, k) \phi_j \wedge \phi_k \right) \wedge \dots \end{aligned}$$

From this we see that

$$\det f = \frac{1}{2^{n/2}} \sum_{j_1, \dots, j_n} D(1, 2; j_1, j_2) \cdots D(n-1, n; j_{n-1}, j_n) \varepsilon^{j_1 \cdots j_n},$$

where

$$\varepsilon^{j_1 \dots j_n} = \begin{cases} 1 & j_1, \dots, j_n \text{ is an even permutation of } 1, \dots, n \\ -1 & j_1, \dots, j_n \text{ is an odd permutation of } 1, \dots, n \\ 0 & j_1, \dots, j_n \text{ are not all distinct.} \end{cases}$$

We can clearly also write

$$\det f = \frac{1}{2^{n/2} n!} \sum_{\substack{i_1, \dots, i_n \\ j_1, \dots, j_n}} D(i_1, i_2; j_1, j_2) \cdots D(i_{n-1}, i_n; j_{n-1}, j_n) \varepsilon^{i_1 \dots i_n} \varepsilon^{j_1 \dots j_n}.$$

Now we apply this formula to evaluate

$$K(p) = \det -dv: M_p \rightarrow M_p$$

in terms of a basis X_1, \dots, X_n of M_p . Using Fact 0 from Chapter 2, we have

$$K = \frac{1}{\det(\langle X_i, X_j \rangle)} \cdot \det(\Pi(X_i, X_j)).$$

For the determinants of the 2×2 submatrices of the matrix $(\Pi(X_i, X_j))$ we have, by Gauss' equation,

$$D(i_1, i_2; j_1, j_2) = \langle R(X_{i_2}, X_{i_1})X_{j_1}, X_{j_2} \rangle.$$

So

$$\begin{aligned} K(p) = \frac{1}{2^{n/2} n!} \sum_{\substack{i_1, \dots, i_n \\ j_1, \dots, j_n}} & \langle R(X_{i_2}, X_{i_1})X_{j_1}, X_{j_2} \rangle \\ & \cdots \langle R(X_{i_n}, X_{i_{n-1}})X_{j_{n-1}}, X_{j_n} \rangle \cdot \frac{\varepsilon^{i_1 \dots i_n} \varepsilon^{j_1 \dots j_n}}{\det(\langle X_i, X_j \rangle)}. \end{aligned}$$

If we have a coordinate system x^1, \dots, x^n on M , and let $X_i = \partial/\partial x^i$, then

$$\begin{aligned} \langle R(X_{i_2}, X_{i_1})X_{j_1}, X_{j_2} \rangle &= \left\langle R\left(\frac{\partial}{\partial x^{i_2}}, \frac{\partial}{\partial x^{i_1}}\right) \frac{\partial}{\partial x^{j_1}}, \frac{\partial}{\partial x^{j_2}} \right\rangle \\ &= R_{j_2 j_1 i_2 i_1} \quad (\text{see pg. II.190}) \\ &= R_{i_1 i_2 j_1 j_2}. \end{aligned}$$

So we can write

$$K = \frac{1}{2^{n/2}n!} \sum_{\substack{i_1, \dots, i_n \\ j_1, \dots, j_n}} R_{i_1 i_2 j_1 j_2} \cdots R_{i_{n-1} i_n j_{n-1} j_n} \cdot \frac{\varepsilon^{i_1 \dots i_n}}{\sqrt{\det(g_{ij})}} \cdot \frac{\varepsilon^{j_1 \dots j_n}}{\sqrt{\det(g_{ij})}}.$$

The symbol $\varepsilon^{i_1 \dots i_n} / \sqrt{\det(g_{ij})}$ which appears in this formula has the following natural interpretation. We have a map

$$\underbrace{M_p^* \times \cdots \times M_p^*}_{n \text{ times}} \xrightarrow{\wedge} \Omega^n(M_p)$$

given by

$$(\phi_1, \dots, \phi_n) \mapsto \phi_1 \wedge \cdots \wedge \phi_n.$$

In particular,

$$(dx^{i_1}(p), \dots, dx^{i_n}(p)) \mapsto \varepsilon^{i_1 \dots i_n} \cdot (dx^1(p) \wedge \cdots \wedge dx^n(p)).$$

Now the metric $\langle \cdot, \cdot \rangle_p$ on M_p determines (compare pg. I.311) two elements of norm 1 in the 1-dimensional vector space $\Omega^n(M_p)$, namely

$$\pm \sqrt{\det(g_{ij}(p))} \cdot dx^1(p) \wedge \cdots \wedge dx^n(p).$$

If we choose an orientation for M , then we have a way of choosing between these two elements (choose the $+$ sign if and only if x^1, \dots, x^n is a positively oriented coordinate system), and we therefore have a map $\Omega^n(M_p) \rightarrow \mathbb{R}$ defined by taking this element to 1. The composition

$$\varepsilon: \underbrace{M_p^* \times \cdots \times M_p^*}_{n \text{ times}} \xrightarrow{\wedge} \Omega^n(M_p) \rightarrow \mathbb{R}$$

is then a contravariant vector field of order n , and its components in the x^1, \dots, x^n coordinate system are precisely $\varepsilon^{i_1 \dots i_n} / \sqrt{\det(g_{ij})}$. If we use \mathcal{R} for the tensor

$$\mathcal{R}(X, Y, Z, W) = \langle R(X, Y)Z, W \rangle,$$

we can then write our formula for K as

$$K = \frac{1}{2^{n/2}n!} \cdot \text{contraction of } (\underbrace{\mathcal{R} \otimes \cdots \otimes \mathcal{R}}_{n/2 \text{ times}} \otimes \varepsilon \otimes \varepsilon).$$

A different choice of orientation for M changes ε to $-\varepsilon$, but doesn't change K .

Proposition 22 also shows that K_2 is invariant under isometry, since

$$\binom{n}{2} K_2(p) = \sigma_2(k_1, \dots, k_n) = \sum_{i < j} k_i k_j = \sigma_1(\{k_i k_j : i < j\}).$$

The other elementary symmetric functions of $\{k_i k_j : i < j\}$ are also invariant under isometry, but in general these functions do not have very nice expressions in terms of k_1, \dots, k_n . More interesting is the fact that K_r is invariant under isometry whenever r is even; this follows from the algebraic fact (Problem 16) that the coefficients of *even* powers of λ in the characteristic polynomial $\chi(\lambda)$ of A can always be expressed in terms of the determinants of the 2×2 submatrices of A .

Now let us consider a hypersurface M^n of a general Riemannian manifold $(N^{n+1}, \langle \cdot, \cdot \rangle)$. We still have a unit normal field ν on M , and corresponding second fundamental form Π with

$$\begin{aligned} \Pi(X_p, Y_p) &= \langle s(X_p, Y_p), \nu(p) \rangle \\ &= \langle \nabla'_{X_p} Y, \nu(p) \rangle = -\langle \nabla'_{X_p} \nu, Y_p \rangle \\ &= \langle A_\nu(X_p), Y_p \rangle. \end{aligned}$$

We can define the **principal directions** at p to be the unit eigenvectors for the self-adjoint map $A_\nu : M_p \rightarrow M_p$, and the **principal curvatures** to be the corresponding eigenvalues. Equivalently, the principal curvatures are the eigenvalues of the symmetric matrix $(\Pi(X_i, X_j))$ for X_1, \dots, X_n an orthonormal basis of M_p . We no longer expect the Theorema Egregium to be true in general—even for surfaces, Gauss' equation for the Gaussian curvature involves not only the metric induced on the surface, but also the curvature of N , which varies from point to point. We do obtain a generalization of the Theorema Egregium in the one case where we would expect it:

24. PROPOSITION. Let N^{n+1} be a Riemannian manifold of constant curvature K_0 . Then for hypersurfaces in N , the set $\{k_i k_j : i < j\}$ of products of principal curvatures is invariant under isometry. Consequently, the Gaussian curvature K_n is invariant under isometry if n is even, and invariant up to sign if n is odd.

PROOF. Exactly like the proof of Proposition 22, except that Gauss' equation gives

$$\tilde{R}(X_i, X_j) = -(k_i k_j + K_0) X_i^* \wedge X_j^*,$$

so the set $\{-k_i k_j - K_0 : i < j\}$ is the set of eigenvalues of the map $X^* \wedge Y^* \mapsto \tilde{R}(X, Y)$. ♦

When we consider submanifolds $M \subset N$ of higher codimension, the definitions given previously no longer make sense. However, if we choose any normal vector $\xi \in M_p^\perp$, then we have the map $A_\xi: M_p \rightarrow M_p$, satisfying

$$\langle s(X, Y), \xi \rangle = \langle A_\xi(X), Y \rangle \quad X, Y \in M_p,$$

so we can define the **principal directions** and **principal curvatures** for ξ to be the unit eigenvectors and corresponding eigenvalues for A_ξ ; equivalently, the principal curvatures are the eigenvalues of the symmetric matrix $(\langle s(X_i, X_j), \xi \rangle)$ for X_1, \dots, X_n an orthonormal basis of M_p . We can then define the (**elementary symmetric**) **curvatures** $K_{1;\xi}, \dots, K_{n;\xi}$ by

$$\binom{n}{j} K_{j;\xi} = \sigma_j(k_1, \dots, k_n),$$

where the k_i are the principal curvatures for ξ . We thus have maps

$$M_p^\perp \rightarrow \mathbb{R} \quad \text{given by} \quad \xi \mapsto K_{j;\xi}.$$

The one interesting (and also very important) case arises for the map

$$M_p^\perp \rightarrow \mathbb{R} \quad \text{given by} \quad \xi \mapsto H_\xi = K_{1;\xi}.$$

This map is *linear*, since $A_{\xi+\xi'} = A_\xi + A_{\xi'}$ and since trace is a linear function of matrices. Therefore there is a unique vector $\eta(p) \in M_p^\perp$ such that

$$\langle \eta(p), \xi \rangle = H_\xi = \frac{\text{trace}(\langle s(X_i, X_j), \xi \rangle)}{n} \quad X_1, \dots, X_n \in M_p \text{ orthonormal}$$

for all $\xi \in M_p^\perp$.

This vector $\eta(p)$ is called the **mean curvature normal** at p . In the case of a hypersurface, $\eta(p) = H(p) \cdot \nu(p)$, where ν is the unit normal (changing ν to $-\nu$ changes H to $-H$, so $H \cdot \nu$ is well-defined). In general, if $\nu_{n+1}, \dots, \nu_m \in M_p^\perp$ is an orthonormal basis, then clearly

$$\eta(p) = \sum_{r=n+1}^m H_{\nu_r} \cdot \nu_r.$$

If, moreover, X_1, \dots, X_n are vector fields tangent to M with $X_1(p), \dots, X_n(p)$ an orthonormal basis for M_p , then

$$\begin{aligned} H_\xi &= \frac{1}{n} \text{trace}(\langle s(X_i(p), X_j(p)), \xi \rangle) \\ &= \frac{1}{n} \sum_{i=1}^n \langle s(X_i(p), X_i(p)), \xi \rangle \\ &= \frac{1}{n} \sum_{i=1}^n \langle \nabla'_{X_i(p)} X_i, \xi \rangle. \end{aligned}$$

Consequently,

$$\begin{aligned}\eta(p) &= \sum_{r=n+1}^m H_{v_r} \cdot v_r \\ &= \frac{1}{n} \sum_{r=n+1}^m \sum_{i=1}^n \langle \nabla'_{X_i(p)} X_i, v_r \rangle \cdot v_r,\end{aligned}$$

whence

$$\eta(p) = \frac{1}{n} \perp \left(\sum_{i=1}^n \nabla'_{X_i(p)} X_i \right), \quad X_1(p), \dots, X_n(p) \text{ orthonormal.}$$

The mean curvature H for a hypersurface, and the mean curvature normal field η in general, will play an important role in Chapter 9.

Even though principal directions and curvatures cannot be defined for submanifolds $M \subset N$ of higher codimension, one definition still makes sense. A point $p \in M$ is called an **umbilic** if the principal curvatures for ξ are all equal, for every $\xi \in M_p^\perp$. In other words, each map $A_\xi: M_p \rightarrow M_p$ must be some multiple of the identity, so for each ξ there must be a λ with

$$A_\xi(X) = \lambda X \implies \langle s(X, Y), \xi \rangle = \lambda \cdot \langle X, Y \rangle \quad \text{for all } X, Y \in M_p.$$

It clearly suffices to have

$$A_{v_r}(X) = \lambda_r X$$

for a basis v_{n+1}, \dots, v_m of M_p^\perp .

If p is an umbilic and we choose an orthonormal basis v_{n+1}, \dots, v_m of M_p^\perp and constants $\lambda_{n+1}, \dots, \lambda_m$ with

$$\langle s(X, Y), v_r \rangle = \lambda_r \langle X, Y \rangle \quad \text{for all } X, Y \in M_p,$$

then

$$s(X, Y) = \sum_{r=n+1}^m \langle s(X, Y), v_r \rangle v_r = \langle X, Y \rangle \cdot \left(\sum_{r=n+1}^m \lambda_r v_r \right).$$

This means that for every $\xi \in M_p^\perp$, and every orthonormal basis X_1, \dots, X_n of M_p , we have

$$\langle s(X_i, X_j), \xi \rangle = \delta_{ij} \left\langle \sum_r \lambda_r v_r, \xi \right\rangle,$$

so

$$\begin{aligned} \frac{1}{n} \text{trace}(\langle s(X_i, X_j), \xi \rangle) &= \frac{1}{n} \left\langle \sum_r \lambda_r v_r, \xi \right\rangle \text{trace}(\delta_{ij}) \\ &= \left\langle \sum_r \lambda_r v_r, \xi \right\rangle. \end{aligned}$$

It follows that $\sum_r \lambda_r v_r$ is precisely $\eta(p)$, so we have

$$s(X, Y) = \langle X, Y \rangle \eta(p), \quad \text{at an umbilic } p.$$

When $s: M_p \times M_p \rightarrow M_p^\perp$ is not the zero map we can set

$$\eta(p) = \sum_{r=m+1}^n \lambda_r v_r = \lambda v_*$$

for a unique non-zero $\lambda \in \mathbb{R}$ and unit vector v_* , and for all $X, Y \in M_p$ we have

$$(*) \quad \begin{cases} \langle s(X, Y), v_* \rangle = \lambda \cdot \langle X, Y \rangle \\ \langle s(X, Y), v \rangle = 0 \quad \text{for } \langle v, v_* \rangle = 0. \end{cases}$$

25. LEMMA. Let $(N^m, \langle \cdot, \cdot \rangle)$ be a space of constant curvature K_0 , and for $n \geq 2$ let M^n be a connected immersed submanifold with all points umbilics. Then either $s = 0$ everywhere, so that M is totally geodesic (by Theorems 1-16 and 1-17), or else $\lambda \neq 0$ is constant and M lies in some $(n+1)$ -dimensional totally geodesic submanifold.

PROOF. Suppose that $s(p) \neq 0$, so that $\lambda(p) \neq 0$. In a neighborhood of p we choose an adapted orthonormal moving frame $X_1, \dots, X_n, X_{n+1}, \dots, X_m$ on M with $X_{n+1} = v_*$ at each point. Then for $1 \leq i \leq n$, and X tangent to M we have, by (*),

$$\psi_i^r(X) = \langle \nabla'_X X_i, X_r \rangle = \langle s(X, X_i), X_r \rangle = \begin{cases} \lambda \langle X, X_i \rangle & r = n+1 \\ 0 & r > n+1, \end{cases}$$

which means that on TM we have

$$\begin{aligned} (1) \quad & \psi_i^{n+1} = \lambda \theta^i \\ (2) \quad & \psi_i^r = 0, \quad r > n+1. \end{aligned}$$

From equation (1) and the Codazzi-Mainardi equations we find that on TM we have

$$\begin{aligned} d\lambda \wedge \theta^i + \lambda d\theta^i &= d\psi_i^{n+1} = - \sum_{\alpha} \psi_{\alpha}^{n+1} \wedge \psi_i^{\alpha} \\ &= - \sum_{k=1}^n \lambda \theta^k \wedge \omega_i^k, \end{aligned}$$

while the first structural equation gives

$$d\theta^i = - \sum_{k=1}^n \omega_k^i \wedge \theta^k = - \sum_{k=1}^n \theta^k \wedge \omega_i^k.$$

So we find that

$$d\lambda \wedge \theta^i = 0, \quad 1 \leq i \leq n.$$

Since $n \geq 2$, this implies that $d\lambda = 0$, so that λ is constant in the neighborhood. This argument shows in general that $\{q \in M : \lambda(q) = \lambda(p)\}$ is open. But this set is also closed, and hence all of M . Thus λ is constant.

Now note that equation (2) gives

$$\begin{aligned} 0 &= d\psi_i^r = - \sum_{\alpha} \psi_{\alpha}^r \wedge \psi_i^{\alpha} = -\psi_{n+1}^r \wedge \lambda \theta^i \\ \implies \psi_{n+1}^r &= 0 \quad \text{on } TM, \quad \text{for } r > n+1. \end{aligned}$$

Therefore

$$\begin{aligned} (3) \quad \nabla'_X v_{\star} &= \nabla'_X X_{n+1} = \sum_{j=1}^n \psi_{n+1}^j(X) \cdot X_j = -\lambda \sum_{j=1}^n \langle X, X_j \rangle \cdot X_j \quad \text{by (1)} \\ &= -\lambda X. \end{aligned}$$

We also have

$$(4) \quad \nabla'_X X_i = \sum_{k=1}^n \psi_i^k(X) X_k + \psi_i^{n+1}(X) \cdot v_{\star} \quad i = 1, \dots, n.$$

Let Δ be the $(n+1)$ -dimensional distribution on M with $\Delta(p) = M_p + \mathbb{R} \cdot v_{\star}(p)$. Equations (3) and (4) and Pre-Lemma 7 show that Δ is parallel along every curve c lying in M . So Corollary 11 implies that M lies in an $(n+1)$ -dimensional totally geodesic subspace of N . ♦

For the case $K_0 = 0$, we can immediately characterize the all-umbilic submanifolds:

26. THEOREM. For $n \geq 2$, let $M^n \subset \mathbb{R}^m$ be a connected immersed submanifold of \mathbb{R}^m with all points umbilics. Then either M lies in some n -dimensional plane or else M lies in some n -dimensional sphere in some $(n+1)$ -dimensional plane.

PROOF. We just have to show that if $\lambda \neq 0$ in Lemma 25, then M lies in a sphere of radius $1/\lambda$. We simply repeat the proof from Lemma 1: Let V be the vector field on \mathbb{R}^m defined by

$$V(p) = p_p \in \mathbb{R}^m_p.$$

Then $\nabla'_X V = X$ for all tangent vectors X of \mathbb{R}^m , so we can write equation (3) in Lemma 25 as

$$\nabla'_X (X_{n+1} + \lambda V) = 0.$$

Thus the vector field $X_{n+1} + \lambda V$ is parallel along M . Identifying tangent vectors of \mathbb{R}^m with elements of \mathbb{R}^m , this means that $X_{n+1} + \lambda V$ is a constant vector v_0 on M , so we have

$$X_{n+1}(p) + \lambda \cdot p = v_0 \in \mathbb{R}^m.$$

Thus

$$p = \frac{v_0 - X_{n+1}(p)}{\lambda}$$

for all $p \in M$, which means that M lies in the sphere of radius $1/\lambda$ around the point v_0/λ . ♦

This proof, which depends so strongly on the special properties of \mathbb{R}^m , breaks down completely when we replace \mathbb{R}^m by a complete simply connected manifold of constant curvature $K_0 \neq 0$. Again we have to exploit different descriptions of these manifolds. First we consider the case $K_0 > 0$.

27. THEOREM. Let $S \subset \mathbb{R}^{m+1}$ be an m -sphere. For $n \geq 2$, let M^n be a connected immersed submanifold of S with all points of M umbilics. Then M is part of an n -sphere.

PROOF. We have $M \subset S \subset \mathbb{R}^{m+1}$, with corresponding covariant differentiations $\nabla, \nabla', \nabla''$. Given $X_p, Y_p \in M_p$, extend them to vector fields X, Y in \mathbb{R}^m

which are tangent to M along M , and tangent to S along S . If $\xi \in M_p^\perp \subset S_p$, then

$$\langle \nabla'_{X_p} Y, \xi \rangle = \langle \nabla'_{X_p} Y, \xi \rangle,$$

since $\nabla'_{X_p} Y$ is the component of $\nabla'_{X_p} Y$ tangent to S ; so we have

$$(1) \quad \langle \nabla'_{X_p} Y, \xi \rangle = \lambda \langle X_p, Y_p \rangle \quad \text{for some } \lambda,$$

since p is an umbilic. On the other hand, if $\mathbf{v} \in S_p^\perp \subset \mathbb{R}^{m+1}_p$ is the unit normal, then

$$(2) \quad \langle \nabla'_{X_p} Y, \mathbf{v} \rangle = \frac{1}{r} \langle X, Y \rangle, \quad r = \text{radius of } S,$$

since all points of S are umbilics in \mathbb{R}^{m+1} . Equations (1) and (2) show that all points of M are umbilics when M is considered as a submanifold of \mathbb{R}^{m+1} . Thus the desired result follows immediately from Theorem 26. ♦

Notice that, as predicted by Lemma 25, an n -sphere $\Sigma \subset S$ is either a totally geodesic submanifold of S (when the radius of Σ equals the radius of S), or else is contained in some $(n+1)$ -dimensional totally geodesic submanifold Σ' of S . In the latter case, Σ is a geodesic sphere in Σ' ; thus we have a complete analogy with Theorem 26.

In order to use the same scheme for investigating all-umbilic submanifolds of H^n , we would first have to consider the all-umbilic submanifolds of \mathbb{R}^{n+1} with the Lorentzian metric; these are the planes $P \subset \mathbb{R}^{n+1}$ of various dimensions, and the quadrics

$$Q = \{p \in P : \langle p - p_0, p - p_0 \rangle = c\} \subset P.$$

Then the all-umbilic submanifolds of H^n must be of the form $H^n \cap P$ or $H^n \cap Q$, and we already noted that the latter submanifolds are contained among the former. However, we merely mentioned, but did not prove, the characterization of the sets $H^n \cap P$. So we will use a different method for the case $K_0 < 0$. We have already used the projective model of H^n in the second proof of Lemma 8. Now we will use the conformal model. We appeal to a classical result about conformally equivalent manifolds.

28. PROPOSITION. Let $f: N \rightarrow \bar{N}$ be a conformal equivalence, and let $M \subset N$ be a submanifold of N with an umbilic $p \in M$. Then $f(p)$ is an umbilic of $f(M) \subset \bar{N}$ (but the λ for $f(p)$ need not be the λ for p).

PROOF. Since the result is purely local, we can assume that the underlying spaces of N and \bar{N} are both \mathbb{R}^m , that f is the identity, that $p = f(p) = 0$, and that $M_p = f(M)_{f(p)}$ is the (x^1, \dots, x^n) -plane $\subset \mathbb{R}^m_0$. The metrics for N and \bar{N} have components $g_{\alpha\beta}$ and $\bar{g}_{\alpha\beta}$ satisfying

$$\bar{g}_{\alpha\beta} = e^{2\sigma} g_{\alpha\beta}$$

for some function σ . Then $\bar{g}^{\alpha\beta} = e^{-2\sigma} g^{\alpha\beta}$, and straightforward calculations show that the corresponding Christoffel symbols satisfy the following equations, in which subscripts on σ denote partial derivatives:

$$\begin{aligned} \overline{[\alpha\beta, \gamma]} &= e^{2\sigma} ([\alpha\beta, \gamma] + g_{\alpha\gamma}\sigma_\beta + g_{\beta\gamma}\sigma_\alpha - g_{\alpha\beta}\sigma_\gamma) \\ \bar{\Gamma}_{\alpha\beta}^\gamma &= \Gamma_{\alpha\beta}^\gamma + \delta_\alpha^\gamma\sigma_\beta + \delta_\beta^\gamma\sigma_\alpha - g_{\alpha\beta} \sum_{\mu=1}^m g^{\gamma\mu}\sigma_\mu. \end{aligned}$$

In particular, for $i, j \leq n$ and $r > n$ we have

$$(1) \quad \bar{\Gamma}_{ij}^r = \Gamma_{ij}^r - g_{ij} \cdot \sum_{\mu=1}^m g^{r\mu}\sigma_\mu.$$

The hypothesis that $p = 0$ is an umbilic point for M means that for each $r > n$ there is a constant λ_r with

$$\Gamma_{ij}^r(0) = \lambda_r g_{ij}(0), \quad 1 \leq i, j \leq n.$$

Then equation (1) gives

$$\bar{\Gamma}_{ij}^r(0) = \left[\lambda_r - \sum_{\mu=1}^m g^{r\mu}(0)\sigma_\mu(0) \right] \cdot g_{ij}(0),$$

which shows that $f(p) = 0$ is an umbilic for $f(M)$. ♦

29. THEOREM. For $n \geq 2$, let M^n be a connected immersed submanifold of $H^m(K_0)$ with all points of M umbilics. Then either M is totally geodesic, or else M is either a geodesic sphere, a horosphere, or an equidistant hypersurface in some $(n+1)$ -dimensional totally geodesic submanifold of $H^m(K_0)$.

PROOF. Immediate from Lemma 25, Theorem 26, Proposition 28, and our discussion of $(B^m, \langle \cdot, \cdot \rangle)$ in section A. ♦

Proposition 28 could just as well be used to prove Theorem 27. Conversely, if we apply the method used in proving Theorem 27 with the results of Theorem 29, then it is not hard to work backwards and verify the description of geodesic spheres, horospheres, and equidistant hypersurfaces in H^n which was given on page 16. A particular consequence of Theorem 29 is also noteworthy: Any n -sphere contained in H^n , and any n -sphere which intersects \mathbb{R}^{m-1} non-orthogonally, lies in some $(n+1)$ -sphere or $(n+1)$ -plane which intersects \mathbb{R}^{m-1} orthogonally. Presumably one could also hack this result out by elementary

geometry.

For an orthonormal frame X_1, \dots, X_n on an all-umbilic hypersurface $M^{m-1} \subset H^m(K_0)$ ($m \geq 3$) with (constant) λ we have

$$\tilde{R}(X_i, X_j) = -(\lambda^2 + K_0)X_i^* \wedge X_j^* \quad (\text{compare page 70}),$$

which implies that

$$\begin{aligned} \langle R(X_i, X_j)X_j, X_i \rangle &= \tilde{R}(X_i, X_j)(X_j, X_i) \\ &= \lambda^2 + K_0, \end{aligned}$$

so that M has constant curvature $\lambda^2 + K_0$. Any two all-umbilic hypersurfaces with the same λ are related by an isometry of $H^m(K_0)$, by the first part of Theorem 21. Moreover, there exists a hypersurface with any given $\lambda \geq 0$ (for $\lambda < 0$ we just have the same hypersurface with the opposite choice of unit normal field). In fact, if $(M, \langle \cdot, \cdot \rangle)$ is a simply connected $(m-1)$ -dimensional manifold of constant curvature $\lambda^2 + K_0$, and we define the tensor S on M by $S(X, Y) = \lambda \langle X, Y \rangle$, then M , together with $\langle \cdot, \cdot \rangle$ and S , satisfies Gauss' equation and the Codazzi-Mainardi equations, so by the second part of Theorem 21 there is an isometry of M into $H^m(K_0)$ with second fundamental form Π satisfying $\Pi = \lambda \cdot I$.

It is not hard to determine how the various λ are attached to the various types of all-umbilic hypersurfaces of $H^m(K_0)$. For simplicity, consider $(B^m, \langle \cdot, \cdot \rangle)$, with constant curvature $K_0 = -1$. We know that the horospheres have constant

curvature $0 = \lambda^2 - 1 \implies \lambda = 1$, while the totally geodesic hypersurfaces have constant curvature $-1 = \lambda^2 - 1 \implies \lambda = 0$. We can take a family of all-

umbilic hypersurfaces passing continuously from a totally geodesic hypersurface to a horosphere, with all members of the family distinct up to isometry of B^m . The intermediate hypersurfaces will be equidistant hypersurfaces, and include all such hypersurfaces (up to isometry of B^m). The corresponding λ 's must vary monotonically from 0 to 1. This shows that equidistant hypersurfaces, and only equidistant hypersurfaces, have $0 < \lambda < 1$. So all $\lambda > 1$ must occur for the geodesic spheres. If λ_r is the λ for the geodesic sphere of radius r around 0, then $r \mapsto \lambda_r$ must be a monotonic function of r . Clearly $\lambda_r \rightarrow \infty$ as $r \rightarrow 0$, and $\lambda_r \rightarrow 1$ as $r \rightarrow \infty$.

We have now generalized essentially the material in Chapter 2 which precedes the discussion of the third fundamental form. The facts about higher fundamental forms in general will be left to the Problems. The next generalization on our agenda is then the following.

30. PROPOSITION. If M^n is a compact submanifold immersed in \mathbb{R}^m , then there is a point $p \in M$ and a normal $\xi \in M_p^\perp$ for which the map $A_\xi: M_p \rightarrow M_p$,

$$\langle A_\xi(X), Y \rangle = \langle s(X, Y), \xi \rangle, \quad X, Y \in M_p,$$

is positive definite. $\langle A_\xi(X), X \rangle > 0$ for $X \neq 0$. So if M is a compact hypersurface, with unit normal field ν , then there is a point $p \in M$ for which $-d\nu: M_p \rightarrow M_p$ is either positive or negative definite (depending on the choice of ν). In particular, the Gaussian curvature $K_n(p)$ is non-zero, and in fact $K_n(p) > 0$ for n even.

PROOF. As in the proof of Proposition 2-8, let p be a point of M furthest from 0. Then the line from 0 to p is normal to M at p , and we choose ξ to be the unit vector in M_p pointing in this direction. The rest of the argument is left as an exercise for the reader. ♦

31. COROLLARY. There are no compact submanifolds M^n immersed in \mathbb{R}^m with mean curvature normal $\eta = 0$. In particular, there are no immersed hypersurfaces in \mathbb{R}^m with mean curvature $H = 0$.

PROOF. If ξ is a normal given by Proposition 30, then

$$\langle \eta(p), \xi \rangle = H_\xi = \text{trace } A_\xi,$$

and $\text{trace } A_\xi > 0$ since A_ξ is positive definite. ♦

Suppose we replace \mathbb{R}^m in Proposition 30 by the space $(B^m, \langle \cdot, \cdot \rangle)$ of constant curvature $K_0 < 0$. If $p \in M$ is a point furthest from 0, then M is contained in the geodesic sphere around 0 which passes through p . All principal curvatures

of this sphere are equal to some $\lambda > \sqrt{-K_0}$ (compare pg. III.64). The geodesic from 0 to p is normal to M at p , and if we choose ξ to be the unit normal in M_p^\perp pointing in this direction, then we will have

$$\langle A_\xi(X), X \rangle \geq \lambda > \sqrt{-K_0}.$$

For a hypersphere M , and a correctly chosen unit normal field v , we thus find that all principal curvatures k_1, \dots, k_n are $\geq \lambda > \sqrt{-K_0}$. Hence

$$K_n(p) = \prod_{i=1}^n k_i \geq \lambda^n > (\sqrt{-K_0})^n.$$

In particular, for n even this holds for either choice of v . We also see that there are no compact immersed submanifolds of N with mean curvature normal $\eta = 0$, and hence no compact immersed hypersurfaces of N with mean curvature $H = 0$.

Now let us replace \mathbb{R}^m by a sphere S of radius $1/\sqrt{K_0}$, for $K_0 > 0$, and suppose moreover, that M is contained in an open hemisphere of S , say the hemisphere centered around the point x . By choosing a point $p \in M$ furthest from x , and a unit normal ξ in M_p pointing along the geodesic from x to p , we find that

$$\langle A_\xi(X), X \rangle \geq \lambda$$

for some $\lambda > 0$. But there is obviously no positive lower bound for all λ 's. For hypersurfaces M we find that $K_n(p) \neq 0$, and $K_n(p) > 0$ for n even, but again there is no positive lower bound for K_n . Similarly, we find that Corollary 31 generalizes to compact submanifolds of an open hemisphere. Naturally, our results break down if we replace the hemisphere by the whole sphere, for the equatorial $(m-1)$ -sphere has second fundamental form $s = 0$. You might think that this is the only exception, but there are actually many other possibilities. In fact, we easily compute that for $p, q \geq 1$ with $p + q = m - 1$, the hypersurface

$$M = \left\{ (x_1, \dots, x_{p+1}, y_1, \dots, y_{q+1}) \in \mathbb{R}^{m+1} : \sum x_k^2 = \frac{p}{m-1} \text{ and } \sum y_k^2 = \frac{q}{m-1} \right\} \\ \subset S^m$$

has mean curvature $H = 0$ in the unit sphere S^m , so there is certainly no point $p \in M$ where $dv: M_p \rightarrow M_p$ is definite.

To complete our generalization of the material in Chapter 2, we want to discuss the relationship between positive curvature and convexity of hypersurfaces. For a hypersurface $M^n \subset \mathbb{R}^{n+1}$, the proper analogue of positivity of the Gaussian curvature at p is the condition that all sectional curvatures at p are positive; equivalently, all principal curvatures should have the same sign, or yet again, the map $dv: M_p \rightarrow M_p$ should be (positive or negative) definite. It is easy to see that definiteness of $dv: M_p \rightarrow M_p$ implies that M locally lies on one side of the tangent hyperplane of M at p . If $dv: M_p \rightarrow M_p$ is merely semi-definite (that is, $\langle dv(X), X \rangle \geq 0$ for all X , or $\langle dv(X), X \rangle \leq 0$ for all X), then no conclusion can be drawn. But if $dv: M_p \rightarrow M_p$ is *not* semi-definite, then M locally lies on both sides of its tangent hyperplane at p . Propositions 2-9 and 2-10 clearly generalize to hypersurfaces in \mathbb{R}^{n+1} ; we will not bother to write down all the details, but will henceforth use the word "convex" for a hypersurface in either of its two equivalent meanings.

32. PROPOSITION.

(1) If M is a convex hypersurface in \mathbb{R}^{n+1} , then $dv: M_p \rightarrow M_p$ is semi-definite for all $p \in M$.

(2) Let M be a compact connected n -manifold, and $f: M \rightarrow \mathbb{R}^{n+1}$ an immersion with normal map n such that $dn: M_p \rightarrow M_p$ is definite for all $p \in M$. Then

- (i) The manifold M is orientable, and the normal map $n: M \rightarrow S^n \subset \mathbb{R}^{n+1}$ is a diffeomorphism.
- (ii) The map $f: M \rightarrow \mathbb{R}^{n+1}$ is an imbedding, and $f(M)$ is convex.

PROOF. This generalization of Hadamard's Theorem (2-11) is proved in exactly the same way as the original. ♦

The most significant part of this result is the fact that the immersion f must be an imbedding. In fact, the definiteness of dv implies that M is locally convex, and there are general arguments to show that a locally convex set in \mathbb{R}^m is actually convex, which implies the theorem for an imbedded hypersurface M . On the other hand, we have already mentioned in Chapter 2 that for $n = 2$ Hadamard's Theorem holds even under the weakened assumption that $K(p) \geq 0$ for all $p \in M$. Here the result is not clear even for imbedded $M \subset \mathbb{R}^3$, since the condition $K \geq 0$ does not imply local convexity for arbitrary (non-compact) M . For example, the graph of $(x, y) \mapsto x^3(1 + y^2)$ has

$K \geq 0$ in a neighborhood of $0 \in \mathbb{R}^3$ (by an easy calculation), but is clearly not locally convex. The extension of Hadamard's Theorem for $K \geq 0$ (and $n = 2$) was originally proved by Chern and Lashof [1], using a little Morse theory. Sacksteder [1] then gave a proof for all n under the weakened assumption that $dn: M_p \rightarrow M_p$ is semi-definite for all $p \in M$; in fact, compactness of M can

be replaced by completeness, provided that there is at least one point $p \in M$ where at least one sectional curvature is non-zero (without this last condition, M might be a generalized cylinder). Sacksteder's proof is more "elementary", and, as one might guess, much harder. (For the case where all $dn: M_p \rightarrow M_p$ are definite, but M is merely complete and immersed, there is an earlier proof by Stoker [1].) Do Carmo and Lima [1] gave a simple proof of a result even more general than Sacksteder's when M is compact: If $f: M^n \rightarrow \mathbb{R}^m$ is an immersion with all maps $A_\xi: M_p \rightarrow M_p$ semi-definite (for $\xi \in M_p^\perp$) for all $p \in M$, and all maps A_ξ definite for at least one $p \in M$ [for $m = n + 1$ this latter condition follows from Proposition 30], then $f(M)$ is contained in some $(n + 1)$ -dimensional plane in \mathbb{R}^m , and f is an imbedding of M as a convex set. In Do Carmo and Lima [2], they also give a simple argument which reproves Sacksteder's result for complete M (but which does not recapture all of the additional information obtained in the course of Sacksteder's analysis).

We can also consider convex sets in spaces of constant curvature K_0 . For $H^m(K_0)$, the definition is precisely the same as for \mathbb{R}^m : a set $A \subset H^m(K_0)$ is convex if A contains the segment of the unique geodesic between p and q whenever $p, q \in A$. For $K_0 > 0$, we consider only an open hemisphere of $S^m(K_0)$, so that there is a unique geodesic between any two points, and the same definition can be used. Since geodesic mappings preserve convexity, we see immediately that Proposition 2-10 generalizes when we replace the tangent plane of M at p by the totally geodesic hypersurface $\exp(M_p)$. Again we will use "convex" for hypersurfaces in either of its two equivalent meanings. It also looks as if we should be able to use geodesic mappings to generalize Proposition 32 to hypersurfaces of $H^{n+1}(K_0)$ and $S^{n+1}(K_0)$. The details of this program turn out to be a little sticky, and since the arguments have been covered in a recent paper, Do Carmo and Warner [1], we will merely quote their results:

33. THEOREM (DO CARMO-WARNER).

(1) If M is a convex hypersurface in $H^{n+1}(K_0)$ for $K_0 < 0$, or a convex hypersurface in a hemisphere of $S^{n+1}(K_0)$ for $K_0 > 0$, then all sectional curvatures of M are $\geq K_0$. Moreover, if ϕ is a geodesic mapping from $H^{n+1}(K_0)$, or a hemisphere of $S^{n+1}(K_0)$, to \mathbb{R}^{n+1} , then all sectional curvatures of M are $> K_0$ at p if and only if all sectional curvatures of $\phi(M)$ are > 0 at $\phi(p)$.

(2) Let M be a compact connected n -manifold, and $f: M \rightarrow S^{n+1}(K_0)$ an immersion, for $K_0 > 0$, such that all sectional curvatures are $\geq K_0$. Then M is orientable, the immersion f is an imbedding, and either $f(M)$ is totally geodesic, or else $f(M)$ is contained in some open hemisphere and is convex.

(3) Let M be a compact connected n -manifold, and $f: M \rightarrow H^{n+1}(K_0)$ an immersion, for $K_0 < 0$, such that all sectional curvatures are $\geq K_0$. Then M is orientable, the immersion f is an imbedding, and $f(M)$ is convex.

In part (2) of this result, compactness of M is really equivalent to completeness, by Corollary 8-22. In part (3), compactness does not follow from completeness, and if we try to deal with complete M in $H^{n+1}(K_0)$ we run into the problem that the image $\phi(H^{n+1}(K_0))$ of the geodesic map $\phi: H^{n+1}(K_0) \rightarrow \mathbb{R}^{n+1}$ is an open ball, and hence $\phi \circ f(M)$ need not be complete. As a matter of fact, part (3) is false if M is merely assumed complete. Even if all sectional curvatures of an immersion $f: M \rightarrow H^{n+1}(K_0)$ are $> K_0$, it does not follow that f is an imbedding. To see this, we consider an immersed, but not imbedded,

surface in \mathbb{R}^3 with everywhere positive curvature. Such a surface cannot be complete in \mathbb{R}^3 , but its intersection with the projective model of H^3 may very well be complete in H^3 , even though its (extrinsic) curvature is > -1 , by part (1) of Theorem 33. Similarly, if $M \subset \mathbb{R}^3$ is the non-convex surface pictured on page 82, with non-negative curvature near 0, then the intersection of M with the projective model of H^3 can be a complete imbedded surface with extrinsic curvature ≥ -1 everywhere, but it will not be convex in H^3 .

As a concluding remark, we point out that a complete convex hypersurface in \mathbb{R}^{n+1} is of very restricted topological type; it is homeomorphic to S^n (if it

is compact) or to \mathbb{R}^n or $S^1 \times \mathbb{R}^{n-1}$ otherwise. On the other hand, there are

complete convex hypersurfaces of H^{n+1} which are homeomorphic to \mathbb{R}^n with any number of holes, as shown below for the projective model of H^3 .

E. FURTHER RESULTS

This section is devoted to generalizations of certain material in Chapters 3 and 4. The first thing we want to consider are ruled surfaces in \mathbb{R}^m , given by

$$f(s, t) = c(s) + t\delta(s)$$

for two curves c and δ in \mathbb{R}^m . When $m = 3$ we found that the surface is flat precisely when c', δ, δ' are everywhere linearly dependent, by using the Gaussian curvature $k_1 \cdot k_2$, the product of the principal curvatures. For $m > 3$, we have to compute the curvature of the surface f from an intrinsic formula. We can assume that $|\delta| = 1$, and hence $\langle \delta, \delta' \rangle = 0$. Then

$$\left. \begin{array}{l} f_1 = c' + t\delta' \\ f_2 = \delta \end{array} \right\} \Rightarrow \left\{ \begin{array}{l} E = \langle f_1, f_1 \rangle = \langle c', c' \rangle + 2t\langle c', \delta' \rangle + t^2\langle \delta', \delta' \rangle \\ F = \langle f_1, f_2 \rangle = \langle c', \delta \rangle \\ G = 1. \end{array} \right.$$

Most of the terms in the formula on pg. II.129 vanish, and we end up with

$$\begin{aligned} 4(EG - F^2)^2 K &= G \cdot \left(\frac{\partial E}{\partial t} \right)^2 - 2(EG - F^2) \frac{\partial^2 E}{\partial t^2} \\ &= [2\langle c', \delta' \rangle + 2t\langle \delta', \delta' \rangle]^2 \\ &\quad - 2[\langle c', c' \rangle + 2t\langle c', \delta' \rangle + t^2\langle \delta', \delta' \rangle - \langle c', \delta \rangle^2] \cdot 2\langle \delta', \delta' \rangle. \end{aligned}$$

The coefficients of t and t^2 vanish, and we find that

$$K = 0 \iff 0 = \langle c', \delta' \rangle^2 - \langle c', c' \rangle \cdot \langle \delta', \delta' \rangle + \langle c', \delta \rangle^2 \cdot \langle \delta', \delta' \rangle.$$

This condition is automatic when $\delta' = 0$. At points where $\delta' \neq 0$, we can write

$$K = 0 \iff \langle c', c' \rangle = \left\langle c', \frac{\delta'}{|\delta'|} \right\rangle^2 + \langle c', \delta \rangle^2.$$

Since $\delta, \delta'/|\delta'|$ are orthonormal, this happens precisely when c' is a linear combination of δ, δ' . So in all cases,

$$K = 0 \iff c', \delta, \delta' \text{ are linearly dependent.}$$

We can now repeat the analysis on pp. III.236–237 and see that flat ruled surfaces in \mathbb{R}^m are “in general” cylinders, cones, or tangents to a curve.

It should be pointed out that there are plenty of *non*-ruled flat surfaces in \mathbb{R}^m for $m > 3$. For example, the torus

$$S^1 \times S^1 \subset \mathbb{R}^2 \times \mathbb{R}^2 = \mathbb{R}^4,$$

with the product metric, is flat.

We can also define **ruled surfaces** in an arbitrary Riemannian manifold $(N^m, \langle \cdot, \cdot \rangle)$. They are the surfaces which can be parameterized as

$$f(s, t) = \exp_{c(s)}(tV(s)),$$

where V is a unit vector field along c .

We want to consider, in particular, the case where N has constant curvature K_0 , and try to describe the ruled surfaces in N which also have constant curvature K_0 . First we consider the case $m = 3$. For a surface $M \subset N^3$ it is important to make a distinction which does not arise in the case of surfaces in \mathbb{R}^3 . The surface M has an induced Riemannian metric, and thus an intrinsic curvature

$$K_{\text{int}}(p) = \langle R(X_p, Y_p)Y_p, X_p \rangle \quad \text{for orthonormal } X_p, Y_p \in M_p.$$

It also has an extrinsic Gaussian curvature $K_{\text{ext}}(p) = k_1 \cdot k_2$, the product of the principal curvatures at p . If N has constant curvature K_0 , then Gauss' equation tells us that

$$(*) \quad K_{\text{int}} = K_{\text{ext}} + K_0.$$

Recall, by the way, that a surface M having constant curvature just means that the function K_{int} on M is constant, while the condition that a higher dimensional manifold have constant curvature is more involved.

The reason for considering the case $m = 3$ first is that in this case the hypothesis that M is ruled is essentially redundant:

34. PROPOSITION. Let N be a 3-dimensional manifold of constant curvature K_0 , and let $M \subset N$ be a surface with constant intrinsic curvature $K_{\text{int}} = K_0$. If $p \in M$ is a point where the second fundamental form $s: M_p \times M_p \rightarrow M_p^\perp$ is not 0, then p has a neighborhood which is a ruled surface.

PROOF. Since M has

$$K_{\text{int}} = K_0 \implies K_{\text{ext}} = 0 \quad \text{by } (*),$$

one principal curvature, k_1 , is always 0. Since s is non-zero at p , the other principal curvature, k_2 , is non-zero in a neighborhood of p . Choose orthonormal vector fields X_1, X_2 on this neighborhood so that each $X_1(q)$ is a principal vector with principal curvature $k_1(q) = 0$, and $X_2(q)$ is a principal vector with principal curvature $k_2(q) \neq 0$. Now the Codazzi-Mainardi equations for N are exactly the same as for \mathbb{R}^3 , so the proof of Proposition 5-4 goes through unchanged, leading to the conclusion that $\nabla'_{X_1} X_1 = 0$, which means that the integral curves of X_1 are geodesics in N . ♦

Naturally, this result does not hold when N has dimension > 3 , so for a general manifold $(N, \langle \cdot, \cdot \rangle)$ of constant curvature K_0 we will now restrict our attention to *ruled* surfaces $M \subset N$. By Synge's inequality (Corollary 1-7) we always have $K_{\text{int}}(p) \leq K_0$. Moreover,

$$K_{\text{int}} = K_0 \text{ along a ruling } \gamma \text{ of } M \iff M_{\gamma(t)} \text{ is parallel along } \gamma.$$

But Lemma 8 shows that

$$M_{\gamma(t)} \text{ is parallel along } \gamma \iff \begin{array}{l} M \text{ is tangent to a} \\ \text{2-dimensional totally geodesic} \\ \text{submanifold of } N \text{ along } \gamma. \end{array}$$

The interesting thing about this last condition is that it does not involve metrics, but only their geodesics. Hence

35. THEOREM. Let N be a manifold of constant curvature K_0 and let $\phi: N \rightarrow \mathbb{R}^m$ be a geodesic mapping. Let $M \subset N$ be a ruled surface. Then M has constant intrinsic curvature $K_{\text{int}} = K_0$ if and only if the ruled surface $\phi(M) \subset \mathbb{R}^m$ is flat.

PROOF. Immediate from the above equivalences. ♦

From Theorem 35 we see that the surfaces $M \subset N$ with $K_{\text{int}} = K_0$ are “in general” ϕ^{-1} of cones, cylinders, and tangent developables. As a local classification, this works equally well for $K_0 < 0$ and $K_0 > 0$. But the situation is quite different when we look for *complete* surfaces with $K_{\text{int}} = K_0$. In the sphere, any pair of geodesics intersect, so there cannot be “cylinders” as in \mathbb{R}^m (this is reflected in the fact that the geodesic mapping from S^m to \mathbb{R}^m is actually defined only on a hemisphere). Once one realizes this, it seems very hard for there to be many such surfaces. In fact, in the next section we will see that in S^3 the only complete surfaces with $K_{\text{int}} = K_0$ are the great 2-spheres. Now consider hyperbolic space H^m . We know that there is a geodesic mapping $\phi: H^m \rightarrow B^m(1)$. Equivalently, there is a metric $\langle \cdot, \cdot \rangle$ on $B^m(1)$ with constant curvature $K_0 < 0$, whose geodesics are just straight lines of \mathbb{R}^m (with a different parameterization). A cone, cylinder, or tangent developable in \mathbb{R}^m then intersects $B^m(1)$ in a surface with $K_{\text{int}} = K_0$ with the metric induced from $\langle \cdot, \cdot \rangle$. The interesting thing is that we can take the vertex of our cone, or the generating curve for the tangent developable to lie *outside* of B . Then

the intersection with B will be a *complete* flat surface, without singularities, of constant intrinsic curvature $K_{\text{int}} = K_0$. Thus there are many such surfaces, of far greater variety than in \mathbb{R}^m . In the next section we will see this in a startling way.

Now consider an oriented surface M in an arbitrary oriented 3-dimensional Riemannian manifold $(N, \langle \cdot, \cdot \rangle)$, and an arclength parameterized curve c in M . We again define the **Darboux frame** of c on M to be the moving frame

$$\mathbf{t}(s) = c'(s), \quad \mathbf{u}(s), \quad \mathbf{v}(s) = \mathbf{t}(s) \times \mathbf{u}(s) = \nu(c(s)),$$

where $\mathbf{u}(s) \in M_{c(s)}$ is a unit vector perpendicular to $\mathbf{t}(s)$ with $(\mathbf{t}(s), \mathbf{u}(s))$ positively oriented in M , and the unit normal field ν is chosen so that the triple

$(\mathbf{t}(s), \mathbf{u}(s), \mathbf{v}(s))$ is positively oriented in N . We still have

$$\begin{aligned}\mathbf{t}' &= \kappa_g \mathbf{u} + \kappa_n \mathbf{v} \\ \mathbf{u}' &= -\kappa_g \mathbf{t} + \tau_g \mathbf{v} \\ \mathbf{v}' &= -\kappa_n \mathbf{t} - \tau_g \mathbf{u}\end{aligned}$$

for certain functions $\kappa_n, \kappa_g, \tau_g$. Everything in Chapter 4 up to and including Proposition 4-5 generalizes almost without any change (asymptotic directions on M are defined just as before, as unit vectors $X \in M_p$ with $\Pi(X_p, X_p) = 0$; they exist only on regions where $K_{\text{ext}}(p) \leq 0$). Moreover, Theorem 4-7 also generalizes, essentially without change. For reference, we merely state this generalization:

36. THEOREM (BELTRAMI-ENNEPER). Let M be a surface in an oriented 3-dimensional Riemannian manifold $(N, \langle \cdot, \cdot \rangle)$. If c is an asymptotic curve in M with $c(0) = p$ and first curvature $\kappa_1(0) \neq 0$, then

$$|\kappa_2(0)| = \sqrt{-K_{\text{ext}}(p)}.$$

Moreover, if $K_{\text{ext}}(p) < 0$ and the two distinct asymptotic curves through p both have non-zero first curvature κ_1 at p , then their second curvatures κ_2 at p are negatives of each other.

The next result generalizes Theorem 4-8.

37. THEOREM. Let N^m be a manifold of constant curvature K_0 , let c be an immersed curve in a hypersurface $M \subset N$, and let S be the ruled surface formed by the geodesics of N which are perpendicular to M along c . Then c is a line of curvature if and only if S has constant intrinsic curvature $K_{\text{int}} = K_0$.

PROOF. Since the result is a local one, we can assume that there is a geodesic mapping $\phi: N \rightarrow \mathbb{R}^m$. The surface S is $\{\exp_{c(s)} t\nu(c(s))\}$, where ν is a unit normal field on M . Hence, identifying tangent vectors of \mathbb{R}^m with elements of \mathbb{R}^m as usual, we have

$$\begin{aligned}\phi(S) &= \{\phi(c(s)) + t\phi_*(\nu(c(s)))\} \\ &= \{\gamma(s) + t\delta(s)\}, \quad \text{say.}\end{aligned}$$

If $\bar{\nabla}$ denotes covariant differentiation in \mathbb{R}^m , then, as in the second proof of Lemma 8, we have

$$\bar{\nabla}_{\phi_* X} \phi_* Y - \phi_*(\nabla'_X Y) = \omega(\phi_* X) \cdot \phi_* Y + \omega(\phi_* Y) \cdot \phi_* X,$$

for some 1-form ω on \mathbb{R}^m . Hence

$$\delta'(s) - \phi_*(\nabla'_{c'(s)}\nu) = \text{a linear combination of } \phi_*(c'(s)) \text{ and } \phi_*(\nu(c(s))).$$

Consequently, we can write

$$(1) \quad \delta'(s) = \phi_*(\nabla'_{c'(s)}\nu) + a\phi_*(c'(s)) + b\phi_*(\nu(c(s))).$$

First suppose that c is a line of curvature, so that $\nabla'_{c'(s)}\nu$ is a multiple of $c'(s)$ for all s . Then equation (1) shows that we can write

$$\begin{aligned} \delta'(s) &= \alpha\phi_*(c'(s)) + b\phi_*(\nu(c(s))) \\ &= \alpha\gamma'(s) + b\delta(s). \end{aligned}$$

So γ', δ, δ' are always linearly independent, and the ruled surface $\phi(S) \subset \mathbb{R}^m$ is flat. Hence S has constant intrinsic curvature $K_{\text{int}} = K_0$ by Theorem 35.

Conversely, if S has constant intrinsic curvature $K_{\text{int}} = K_0$, then $\phi(S)$ is flat, so γ', δ, δ' are always linearly dependent. Then (1) shows that for each s there are numbers A, B, C , not all 0, with

$$(2) \quad Ac'(s) + B\nu(c(s)) + C[\nabla'_{c'(s)}\nu + ac'(s) + b\nu(c(s))] = 0.$$

Clearly $C \neq 0$. Taking the inner product of (2) with $\nu(c(s))$ gives

$$B + Cb = 0,$$

and hence (2) becomes

$$(A + Ca)c'(s) + C\nabla'_{c'(s)}\nu = 0,$$

which shows that c is a line of curvature. ♦

In Eisenhardt [1; pg. 213] this result is verified in a more direct way, by using special coordinates—the Weierstrass coordinates. I like the above proof because it has the strange feature that it uses geodesic mappings even though such mappings preserve neither perpendicularity nor lines of curvature. Once one realizes this, it becomes clear how to generalize the theorem vastly (Problem 19).

F. COMPLETE SURFACES OF CONSTANT CURVATURE

In this section we will classify, so far as possible, the complete constant curvature surfaces in the complete simply-connected 3-dimensional manifolds of constant curvature. First consider a surface M in any 3-dimensional manifold $(N, \langle \cdot, \cdot \rangle)$. By Corollary 4-17, for any point $p \in M$ we can find an imbedding $f: U \rightarrow M$ with $U \subset \mathbb{R}^2$ open and $p \in f(U)$ whose coordinate lines are the lines of curvature, or the asymptotic lines [if $K_{\text{ext}}(p) < 0$]. We want to see what the formulas in the Addendum to Chapter 4 become in these cases. As before, E, F, G are the components of $f^*\langle \cdot, \cdot \rangle$ with respect to the standard coordinate system (s, t) on \mathbb{R}^2 , while l, m, n are the components of $f^*\text{II}$, where II is the second fundamental form of the hypersurface $M \subset N$ for some choice of a unit normal field ν on M . The formula in Problem 4-13 gives the intrinsic curvature K_{int} , so we see that

(A) When the parameter lines of $M^2 \subset N^3$ are orthogonal, we have

$$F = 0$$

$$K_{\text{int}} = -\frac{1}{2\sqrt{EG}} \left[\left(\frac{E_2}{\sqrt{EG}} \right)_2 + \left(\frac{G_1}{\sqrt{EG}} \right)_1 \right].$$

We also know that the Codazzi-Mainardi equations for an ambient manifold of constant curvature are the same as in the Euclidean case, so

(B) When N^3 has constant curvature and the parameter lines of $M^2 \subset N^3$ are lines of curvature, we have

$$l = k_1 E, \quad n = k_2 G, \quad m = 0, \quad F = 0$$

$$l_2 = \frac{E_2}{2} \left(\frac{l}{E} + \frac{n}{G} \right)$$

$$n_1 = \frac{G_1}{2} \left(\frac{l}{E} + \frac{n}{G} \right).$$

(C) When N^3 has constant curvature and the parameter lines of $M^2 \subset N^3$ are asymptotic curves, we have

$$l = n = 0$$

$$m_1 = \frac{\left[\frac{1}{2}(EG - F^2)_1 + FE_2 - EG_1 \right]}{EG - F^2} \cdot m$$

$$m_2 = \frac{\left[\frac{1}{2}(EG - F^2)_2 + FG_1 - GE_2 \right]}{EG - F^2} \cdot m.$$

Recall, finally, that when N has constant curvature K_0 , the intrinsic curvature K_{int} of M and the extrinsic curvature K_{ext} are related by

$$(*) \quad K_{\text{int}} = K_{\text{ext}} + K_0.$$

The first thing we are going to do is to see what the basic lemmas of Chapter 5 give in our more general situation. The main problem is keeping track of the times when the curvature K in the Euclidean case should be replaced by K_{int} and when it should be replaced by K_{ext} .

38. LEMMA. Let M be a surface immersed in a 3-manifold N of constant curvature, and let $p \in M$ be a non-umbilic point. Let $k_1 \geq k_2$ be the two principal curvatures on M and suppose that k_1 has a local maximum at p , and k_2 has a local minimum at p . Then $K_{\text{int}}(p) \leq 0$.

PROOF. The proof is exactly the same as the proof of Lemma 5-1. ♦

39. THEOREM. Let N be a 3-manifold of constant curvature. If M is a compact connected surface in N with constant extrinsic curvature $K_{\text{ext}} \geq 0$ and (constant) intrinsic curvature $K_{\text{int}} > 0$, then all points of M are umbilics.

PROOF. First suppose that $K_{\text{ext}} > 0$. As in the proof of Theorem 5-2, let $k_1 \geq k_2$ be the principal curvatures and let k_1 achieve its maximum at p . Then $k_2 = K_2/k_1$ has its minimum at p . If p were not an umbilic, then by Lemma 38 we would have $K_{\text{int}}(p) \leq 0$, contradicting the hypothesis. So $k_1(p) = k_2(p)$, and, reasoning as in the proof of Theorem 5-2, we see that all points are umbilics.

Next suppose that $K_{\text{ext}} = 0$. Suppose there is a non-umbilic point $p \in M$. Then $0 = k_1(p) \cdot k_2(p)$, but $k_1(p) \neq k_2(p)$, so either $k_1(p) > 0$ or $0 > k_2(p)$, say the first. Let \bar{p} be the point where k_1 takes on its maximum $k_1(\bar{p}) > 0$. Then $k_1 > 0$ in a whole neighborhood of \bar{p} , so $k_2 = 0$ in a whole neighborhood of \bar{p} , and hence k_2 has a local minimum at \bar{p} . Then Lemma 38 gives $K_{\text{int}}(\bar{p}) \leq 0$, a contradiction. ♦

40. THEOREM. Let N be a 3-manifold of constant curvature. Let M be a 2-dimensional immersed submanifold of N with constant extrinsic curvature $K_{\text{ext}} < 0$. Then for every point $p \in M$ there is a diffeomorphism

$$g: (-\varepsilon, \varepsilon) \times (-\varepsilon, \varepsilon) \rightarrow M$$

$$g(0, 0) = p$$

whose parameter curves are asymptotic curves *parameterized by arclength*.

PROOF. The proof is exactly the same as the first proof of Lemma 5-10. ❖

41. **THEOREM.** Let N be a 3-manifold of constant curvature. Then there is no complete surface M immersed in N with constant extrinsic curvature $K_{\text{ext}} < 0$ and (constant) intrinsic curvature $K_{\text{int}} < 0$.

PROOF. Suppose such a surface M existed. Using Theorem 40, we can repeat the first argument in the (first) proof of Theorem 5-12 *verbatim* and conclude that there is a Tschebyscheff net $f: \mathbb{R}^2 \rightarrow M$. If ω is the angle between the first and second parameter lines, then by Lemma 5-11 we have

$$\frac{\partial^2 \omega}{\partial s \partial t} = (-K_{\text{int}}) \sin \omega \quad 0 < \omega < \pi,$$

where $-K_{\text{int}}$ is a positive constant. Then part (B) of the proof of Theorem 5-12 shows that there is no such ω . ❖

Now we will begin putting these results together. Take N to be S^3 , with constant curvature 1, and consider the possibilities for complete surfaces in S^3 with constant extrinsic curvature K_{ext} . Since equation (*) now becomes

$$K_{\text{int}} = K_{\text{ext}} + 1,$$

we see that $K_{\text{ext}} < -1 \implies K_{\text{int}} < 0$. So Theorem 41 shows that there are no complete surfaces immersed in S^3 with constant $K_{\text{ext}} < -1$. We also see that $K_{\text{ext}} \geq 0 \implies K_{\text{int}} > 0$, so Theorem 39 and Theorem 27 show that the only compact surfaces in S^3 with constant $K_{\text{ext}} \geq 0$ are spheres (Theorem 8-17 again shows that compactness can be replaced by completeness).

How about the range $-1 \leq K_{\text{ext}} < 0$? First of all we have

42. **PROPOSITION.** There are no complete surfaces M immersed in S^3 with constant K_{ext} satisfying $-1 < K_{\text{ext}} < 0$.

PROOF. The intrinsic curvature of M would satisfy $K_{\text{int}} > 0$, so M would be compact, by Theorem 8-17. We can assume that M is orientable, for otherwise we can look at the orientable 2-fold covering of M , which will also be immersed, with the same K_{ext} . Then M must be homeomorphic to S^2 , by the Gauss-Bonnet Theorem. Since $K_{\text{ext}} < 0$, at every point $p \in S^2$ the principle curvatures $k_1(p), k_2(p)$ have opposite signs. By choosing the vectors pointing in the principal directions which correspond to the positive principal curvature, we would have a continuous choice of 1-dimensional subspaces of S^2_p . But this is impossible (Problem I.9-7). ♦

This leaves only the isolated possibility $K_{\text{ext}} = -1$. Oddly enough, there *are* complete surfaces in S^3 with $K_{\text{ext}} = -1$ (equivalently, $K_{\text{int}} = 0$). In fact, for $\rho, \sigma > 0$ with $\rho + \sigma = 1$, the torus

$$\{x \in \mathbb{R}^4 : x_1^2 + x_2^2 = \rho \text{ and } x_3^2 + x_4^2 = \sigma\} \subset S^3$$

is a (flat) product of two circles. Moreover, there is an infinite variety of other complete flat surfaces in S^3 . Such surfaces can be classified, modulo a few sticky details, and we will essentially find the most general way to construct them. The classification actually works even for a piece of a flat surface, but we will deal only with complete surfaces, just to simplify some of the description; this classification is based on the work of Bianchi [1].

It will be necessary to first consider some of the geometry which is special to the manifold S^3 . For two points $x, y \in S^3$, the distance $d(x, y)$ between x and y as elements of S^3 (*not* the Euclidean distance between x and y) is just the radian measure of the angle between x and y . Consequently, we have

$$(1) \quad \cos d(x, y) = \langle x, y \rangle.$$

Now we ask whether there are any isometries $A \in O(4)$ of S^3 with the property that $d(x, A(x))$ is the same for all $x \in S^3$. Such isometries would be the analogues of the translations in \mathbb{R}^n ; notice that S^2 , for example, certainly has no isometries with this property, other than the identity, since every $A \in O(3)$ has a fixed point in S^2 . If $A = (a_{ij})$, then

$$\langle x, Ax \rangle = \sum_{i,j=1}^4 a_{ji} x_j x_i.$$

Taking into account equation (1) we see that we are looking for A with

$$\sum_{i,j=1}^4 a_{ji} x_j x_i = \text{constant} \quad \text{for all } x \in S^4.$$

This implies that

$$\sum_{i,j=1}^4 a_{ji} x_j x_i = (\text{constant}) \cdot \sum_{i=1}^4 x_i^2 \quad \text{for all } x \in \mathbb{R}^4.$$

Regarding this as a polynomial identity in the variables x_1, \dots, x_4 we see that we must have

$$a_{11} = a_{22} = a_{33} = a_{44}, \quad a_{ij} + a_{ji} = 0, \quad i \neq j.$$

Since A is also orthogonal we have

$$(2) \quad 0 = a_{11}a_{12} + a_{21}a_{22} + a_{31}a_{32} + a_{41}a_{42} = a_{31}a_{32} + a_{41}a_{42}$$

as well as

$$a_{11}^2 + a_{21}^2 + a_{31}^2 + a_{41}^2 = a_{12}^2 + a_{22}^2 + a_{32}^2 + a_{42}^2$$

$$\Downarrow$$

$$(3) \quad a_{31}^2 + a_{41}^2 = a_{32}^2 + a_{42}^2.$$

Equation (2) says that the vectors $(a_{31}, a_{41}), (a_{32}, a_{42}) \in \mathbb{R}^2$ are perpendicular, while equation (3) says that they have the same length. It follows that

$$\left. \begin{array}{l} a_{32} = a_{41} \\ a_{42} = -a_{31} \end{array} \right\} \quad \text{or} \quad \left\{ \begin{array}{l} a_{32} = -a_{41} \\ a_{42} = +a_{31} \end{array} \right.$$

We thus find two different kinds of A 's with the desired property:

$$\begin{pmatrix} a & -b & -c & -d \\ b & a & -d & c \\ c & d & a & -b \\ d & -c & b & a \end{pmatrix} \quad \text{or} \quad \begin{pmatrix} a & b & c & d \\ -b & a & -d & c \\ -c & d & a & -b \\ -d & -c & b & a \end{pmatrix}$$

$$a^2 + b^2 + c^2 + d^2 = 1.$$

The existence of these “translations” in S^3 is directly related to the fact that S^3 is a group, the group of quaternions of norm 1. Recall that the quaternions are \mathbb{R}^4 with the structure of a non-commutative division algebra over \mathbb{R} having unit $1 = (1, 0, 0, 0)$ and elements

$$i = (0, 1, 0, 0), \quad j = (0, 0, 1, 0), \quad k = (0, 0, 0, 1)$$

satisfying

$$\begin{aligned} i \cdot j &= k = -j \cdot i \\ j \cdot k &= i = -k \cdot j \quad \text{and} \quad i \cdot i = j \cdot j = k \cdot k = -1. \\ k \cdot i &= j = -i \cdot k \end{aligned}$$

The norm $|x|$ of a quaternion x satisfies $|xy| = |x| \cdot |y|$, so the quaternions of norm 1 (i.e., S^3) are a non-commutative Lie group. It is easily checked that the two matrices given above are just left and right translation by the quaternion $a + bi + cj + dk \in S^3$. In particular, this shows that the usual Riemannian metric on S^3 is left and right invariant. Moreover, the map

$$a + bi + cj + dk \mapsto \begin{pmatrix} a & -b & -c & -d \\ b & a & -d & c \\ c & d & a & -b \\ d & -c & b & a \end{pmatrix}$$

is an isomorphism of S^3 into a subgroup of $O(4)$, namely the subgroup of all left translations by elements of S^3 . It will be convenient to identify S^3 with a subgroup of $O(4)$ by this isomorphism.

We will need the first part of the following general result; the other parts are included for independent interest.

43. THEOREM. Let G be a Lie group with bi-invariant metric $\langle \cdot, \cdot \rangle$. If X, Y, Z, W are left invariant vector fields on G , then

$$(1) \quad \nabla_X Y = \frac{1}{2}[X, Y]$$

- (2) $\langle [X, Y], Z \rangle = \langle X, [Y, Z] \rangle$
 (3) $R(X, Y)Z = -\frac{1}{4}[[X, Y], Z]$
 (4) $\langle R(X, Y)Z, W \rangle = -\frac{1}{4}\langle [X, Y], [Z, W] \rangle$.

PROOF. The integral curves of X are left translates of 1-parameter subgroups (recall the second proof of Corollary I.10-8). Consequently, they are geodesics (Proposition I.10-21). This means that $\nabla_X X = 0$. So

$$0 = \nabla_{X+Y} X + Y = \nabla_X X + \nabla_X Y + \nabla_Y X + \nabla_Y Y = \nabla_X Y + \nabla_Y X.$$

But also

$$\nabla_X Y - \nabla_Y X = [X, Y],$$

which gives (1).

For (2) we note that

$$\begin{aligned} 0 = Y \langle X, Z \rangle &= \langle \nabla_Y X, Z \rangle + \langle X, \nabla_Y Z \rangle \\ &= \frac{1}{2} \langle [Y, X], Z \rangle + \frac{1}{2} \langle X, [Y, Z] \rangle. \end{aligned}$$

For (3) we have

$$\begin{aligned} R(X, Y)Z &= \nabla_X(\nabla_Y Z) - \nabla_Y(\nabla_X Z) - \nabla_{[X, Y]}Z \\ &= \frac{1}{4}[X, [Y, Z]] - \frac{1}{4}[Y, [X, Z]] - \frac{1}{4}[[X, Y], Z], \end{aligned}$$

which gives the desired result when we apply the Jacobi identity.

Finally, (4) follows from (2) and (3). ♦

Now we want to look at the Lie algebra $\mathcal{L}(S^3)$ of the group S^3 . This is the tangent space of S^3 at $(1, 0, 0, 0)$, and is therefore spanned by the vectors

$$X_1 = (0, 1, 0, 0)$$

$$X_2 = (0, 0, 1, 0)$$

$$X_3 = (0, 0, 0, 1),$$

regarded as tangent vectors at $(1, 0, 0, 0)$. Notice that $X_1 = c'(0)$, where

$$\begin{aligned} c(t) &= (\cos t, \sin t, 0, 0) \in S^3 \\ &= \cos t + (\sin t)i \\ &= \begin{pmatrix} \cos t & -\sin t & 0 & 0 \\ \sin t & \cos t & 0 & 0 \\ 0 & 0 & \cos t & -\sin t \\ 0 & 0 & \sin t & \cos t \end{pmatrix}. \end{aligned}$$

under the identification of S^3 with a subgroup of $O(4)$. Thus X_1 can be identified with

$$c'(0) = \begin{pmatrix} 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \end{pmatrix} \in \mathfrak{o}(4).$$

Similarly X_2 and X_3 can be identified with

$$\begin{pmatrix} 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} 0 & 0 & 0 & -1 \\ 0 & 0 & -1 & 0 \\ 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{pmatrix}.$$

A short calculation then shows that

$$(1) \quad [X_1, X_2] = 2X_3, \quad [X_2, X_3] = 2X_1, \quad [X_3, X_1] = 2X_2.$$

If we think of the X_i as vectors in \mathbb{R}^3 , by simply ignoring their first components, then we have

$$X_1 \times X_2 = X_3, \quad X_2 \times X_3 = X_1, \quad X_3 \times X_1 = X_2.$$

Equivalently, this relation holds when we define \times in $S^3_{(1,0,0,0)}$ in terms of the usual inner product and the usual orientation for S^3 . So if \tilde{X}_i is the left invariant vector field on S^3 which extends X_i , then

$$(2) \quad \tilde{X}_1 \times \tilde{X}_2 = \tilde{X}_3, \quad \tilde{X}_2 \times \tilde{X}_3 = \tilde{X}_1, \quad \tilde{X}_3 \times \tilde{X}_1 = \tilde{X}_2,$$

where \times in each tangent space is defined in terms of the usual metric $\langle \cdot, \cdot \rangle$ on S^3 and the usual orientation for S^3 .

Now the theory of curves in S^3 can be given a special development, because we can express all tangent vectors in terms of the left invariant vector fields \tilde{X}_i . Suppose c is a curve in S^3 parameterized by arclength, and let the unit tangent vector $\mathbf{t} = \mathbf{v}_1$ of c be given by

$$(3) \quad \mathbf{t}(s) = \sum_{i=1}^3 f_i(s) \cdot \tilde{X}_i(c(s)),$$

where

$$(4) \quad \sum_i f_i^2 = 1 \implies \sum_i f_i f_i' = 0.$$

As usual, we denote the covariant derivative in our ambient manifold S^3 by ∇' . Then for any vector field $\sum_j h_j(s) \cdot \tilde{X}_j(c(s))$ along c we have

$$\begin{aligned} \frac{D'}{ds} \left[\sum_j h_j(s) \cdot \tilde{X}_j(c(s)) \right] &= \sum_j h_j'(s) \cdot \tilde{X}_j(c(s)) + \sum_j h_j(s) \frac{D'}{ds} \tilde{X}_j(c(s)) \\ &= \sum_j h_j'(s) \cdot \tilde{X}_j(c(s)) \\ &\quad + \sum_j h_j(s) \sum_i f_i(s) \nabla'_{\tilde{X}_i} \tilde{X}_j(c(s)). \end{aligned}$$

Using Theorem 43 to write $\nabla'_{\tilde{X}_i} \tilde{X}_j = \frac{1}{2}[\tilde{X}_i, \tilde{X}_j]$, and computing the brackets from (1), we get

$$(5) \quad \frac{D'}{ds} \left[\sum_j h_j(s) \cdot \tilde{X}_j(c(s)) \right] = \sum_j h_j' \cdot \tilde{X}_j + [(f_2 h_3 - f_3 h_2) \tilde{X}_1 + (f_3 h_1 - f_1 h_3) \tilde{X}_2 + (f_1 h_2 - f_2 h_1) \tilde{X}_3]$$

{all functions evaluated at s , all \tilde{X}_i at $c(s)$ }.

In particular, we have

$$(6) \quad \frac{D' \mathbf{t}(s)}{ds} = \sum_i f_i' \cdot \tilde{X}_i;$$

hence the curvature $\kappa (= \kappa_1)$ is given by

$$(7) \quad \kappa = \sqrt{\sum_i (f_i')^2},$$

and $\mathbf{n} = \mathbf{v}_2$ is given by

$$(8) \quad \mathbf{n} = \frac{\sum_i f_i' \cdot \tilde{X}_i}{\kappa}.$$

Therefore $\mathbf{b} = \mathbf{v}_3$ is given by

$$\begin{aligned} (9) \quad \mathbf{b} = \mathbf{t} \times \mathbf{n} &= \frac{1}{\kappa} \cdot \left(\sum_i f_i \cdot \tilde{X}_i \right) \times \left(\sum_j f_j' \cdot \tilde{X}_j \right) \\ &= \frac{1}{\kappa} \sum_{i,j} f_i f_j' (\tilde{X}_i \times \tilde{X}_j) \\ &= \frac{1}{\kappa} [(f_2 f_3' - f_3 f_2') \tilde{X}_1 + (f_3 f_1' - f_1 f_3') \tilde{X}_2 + (f_1 f_2' - f_2 f_1') \tilde{X}_3] \\ &\quad \text{by (2)} \\ &= \frac{1}{\kappa} \sum_i g_i \cdot \tilde{X}_i, \quad \text{say.} \end{aligned}$$

Now we have

$$\begin{aligned}
 \frac{D'\mathbf{b}(s)}{ds} &= \frac{1}{\kappa} \frac{D'}{ds} \left(\sum_i g_i \cdot \tilde{X}_i \right) - \frac{\kappa'}{\kappa^2} \sum_i g_i \cdot \tilde{X}_i \\
 &= \frac{1}{\kappa} \left[(f_2 g_3 - g_2 f_3) \tilde{X}_1 + \cdots + \sum_i g_i' \tilde{X}_i \right] - \frac{\kappa'}{\kappa^2} \sum_i g_i \tilde{X}_i \quad \text{by (5)} \\
 &= \frac{1}{\kappa} [(f_2 g_3 - g_2 f_3) \tilde{X}_1 + \cdots] + \sum_i \left(\frac{g_i}{\kappa} \right)' \tilde{X}_i.
 \end{aligned}$$

But

$$\begin{aligned}
 f_2 g_3 - g_2 f_3 &= f_2(f_1 f_2' - f_2 f_1') - f_3(f_3 f_1' - f_1 f_3') \quad \text{by (9)} \\
 &= f_1(f_2 f_2' + f_3 f_3') - f_1'(f_2^2 + f_3^2) \\
 &= f_1(-f_1 f_1') - f_1'(1 - f_1^2) \quad \text{by (4)} \\
 &= -f_1',
 \end{aligned}$$

and similarly for the other terms. Hence we obtain

$$\begin{aligned}
 (10) \quad \frac{D'\mathbf{b}(s)}{ds} &= \frac{-\sum_i f_i' \cdot \tilde{X}_i}{\kappa} + \sum_i \left(\frac{g_i}{\kappa} \right)' \cdot \tilde{X}_i \\
 &= -\mathbf{n} + \sum_i \left(\frac{g_i}{\kappa} \right)' \cdot \tilde{X}_i \quad \text{by (8)}.
 \end{aligned}$$

We therefore have the rather remarkable, and for us very important

44. THEOREM. If c is a curve in S^3 whose torsion τ ($= \kappa_2$) satisfies $\tau = 1$ everywhere, then \mathbf{b} is left invariant along c , that is,

$$b(s) = L_{c(s)c(0)^{-1}*} b(0).$$

If c has torsion $\tau = -1$ everywhere, then \mathbf{b} is right invariant along c .

PROOF. The Serret-Frenet formulas give

$$\frac{D\mathbf{b}(s)}{ds} = -\tau \mathbf{n}.$$

So $\tau = 1$ implies that $(g_i/\kappa)' = 0$, and hence that g_i/κ is constant. But equation (9) shows that g_i/κ are the components of \mathbf{b} with respect to the left invariant vector fields \tilde{X}_i .

To deduce the second part of the theorem, consider the map $f(x) = x^{-1}$ of S^3 into itself. This map reverses 1-parameter subgroups through $(1, 0, 0, 0)$, so $f_*: \mathcal{L}(S^3) \rightarrow \mathcal{L}(S^3)$ is multiplication by -1 . This shows that f is orientation reversing. It follows that the binormal of the curve $f \circ c$ is $-f_*\mathbf{b}$. Thus $f \circ c$ has $\tau = 1$ if and only if c has $\tau = -1$. ♦

Finally we are ready to consider connected immersed surfaces M in S^3 with $K_{\text{ext}} = -1$, and hence $K_{\text{int}} = 0$. We consider only oriented M ; non-orientable surfaces may then be analyzed by considering the 2-fold oriented covering of M . Since $K_{\text{ext}} < 0$, there are 2 distinct asymptotic directions at each point. The argument in the (first) proof of Theorem 5-12, in conjunction with Theorem 40, again shows that there is a Tsychebyscheff net $f: \mathbb{R}^2 \rightarrow M$. It is not hard to see that f is actually onto M (by essentially the argument used in the second proof of Theorem 5-12; for this part, it is not necessary that the ϕ_s be defined for all $s \in \mathbb{R}$, and simple-connectivity is irrelevant). The metric $I_f = f^*\langle \cdot, \cdot \rangle$ on \mathbb{R}^2 is then

$$I_f = f^*\langle \cdot, \cdot \rangle = ds \otimes ds + \cos \omega [ds \otimes dt + dt \otimes ds] + dt \otimes dt,$$

where ω is the oriented angle between the first and second parameter curves.

Now consider the curve $c(s) = (s, t)$ in \mathbb{R}^2 , which is an arclength parameterized curve for the metric I_f . Its tangent vector $c'(s) = \partial/\partial s$ is a unit vector for the metric I_f . If D/ds temporarily denotes the covariant derivative determined by the metric I_f , then from the formula on pg. II.232 we compute that

$$\frac{Dc'(s)}{ds} = \frac{\frac{\partial \omega}{\partial s}}{\sin \omega} \cdot \left[\cos \omega \cdot \frac{\partial}{\partial s} - \frac{\partial}{\partial t} \right].$$

If $\left(\frac{\partial}{\partial s}\right)^\perp$ is the unique vector field with $\frac{\partial}{\partial s}, \left(\frac{\partial}{\partial s}\right)^\perp$ orthonormal for the metric I_f and $\frac{\partial}{\partial s}, \left(\frac{\partial}{\partial s}\right)^\perp$ positively oriented, then

$$\frac{\partial}{\partial t} = \cos \omega \cdot \frac{\partial}{\partial s} + \sin \omega \cdot \left(\frac{\partial}{\partial s}\right)^\perp,$$

so we find that

$$\frac{Dc'(s)}{ds} = -\frac{\frac{\partial \omega}{\partial s}}{\sin \omega} \cdot \left(\frac{\partial}{\partial s}\right)^\perp.$$

Equivalently, if \mathbf{t} denotes the (unit) tangent vector to the parameter curve $s \mapsto f(s, t)$ in M , and D/ds now denotes the covariant derivative in M , then

$$\frac{D\mathbf{t}}{ds} = -\frac{\frac{\partial \omega}{\partial s}}{\sin \omega} \cdot \mathbf{u},$$

where \mathbf{u} is the unique tangent vector field along $s \mapsto f(s, t)$ with \mathbf{t}, \mathbf{u} orthonormal and (\mathbf{t}, \mathbf{u}) positively oriented. But $s \mapsto f(s, t)$ is an asymptotic curve, so the

covariant derivative $D\mathbf{t}/ds$ in M is the same as the covariant derivative $D'\mathbf{t}/ds$ in S^3 (recall the equivalences on pg. III.196). So we have

$$(1) \quad \frac{D'\mathbf{t}}{ds} = -\frac{\partial\omega}{\partial s} \cdot \mathbf{u}.$$

This shows that

$$\begin{aligned} \mathbf{u} &= \text{normal } \mathbf{n} \text{ to the curve } s \mapsto f(s, t) \\ \left| \frac{\partial\omega}{\partial s}(s, t) \right| &= \text{curvature } \kappa(s) \text{ of the curve } s \mapsto f(s, t). \end{aligned}$$

On the other hand, Lemma 5-11 shows that ω satisfies

$$\frac{\partial^2\omega}{\partial s\partial t} = 0,$$

which implies that there are functions S and T with

$$\omega(s, t) = S(s) + T(t),$$

so that

$$\frac{\partial\omega}{\partial s}(s, t) = S'(s) \quad \text{and} \quad \frac{\partial\omega}{\partial t}(s, t) = T'(t).$$

Thus the arclength parameterized curves $s \mapsto f(s, t)$ all have the *same* curvature functions $\kappa(s) = |S'(s)|$. Similarly, all curves $t \mapsto f(s, t)$ have the same curvature functions $|T'(t)|$.

But even more is true. For the Beltrami-Enneper Theorem (Theorem 36) tells us that the torsion τ of the asymptotic curves $s \mapsto f(s, t)$ and $t \mapsto f(s, t)$ satisfies $\tau^2 = 1$ at points where $\kappa \neq 0$, and that the two asymptotic curves through a point have torsions of opposite signs if they both have $\kappa \neq 0$ at that point. We will first assume that for both sets of parameter curves κ is never 0. Then one set of parameter curves must have $\tau = 1$ everywhere, and the other set must have $\tau = -1$ everywhere. For definiteness, say that the curves $s \mapsto f(s, t)$ have $\tau = 1$. We now see that *all* curves $s \mapsto f(s, t)$ are congruent, and similarly *all* curves $t \mapsto f(s, t)$ are congruent.

Let A_s be the unique isometry of S^3 onto itself with $A_s(f(0, t)) = f(s, t)$ for all t . Under the family of isometries $\{A_s\}$, each point $f(0, t)$ moves along the arclength parameterized curve $s \mapsto f(s, t)$. This strongly suggests that all the A_s are actually translations. In fact, we claim that all A_s are left translations.

To prove this, we consider the family of left translations $\{B_s\} = \{L_{f(s,0)f(0,0)^{-1}}\}$ which take $f(0, 0)$ to $f(s, 0)$. According to Theorem 44, B_{s*} takes the binormal $\mathbf{b}(0)$ of $s \mapsto f(s, 0)$ at $s = 0$ into the binormal $\mathbf{b}(s)$ at s . Consequently, B_{s*} takes the osculating plane of this curve at 0 into the osculating plane at s . Hence we can write

$$\mathbf{t}(s) = \cos \theta(s) \cdot B_{s*}\mathbf{t}(0) - \sin \theta(s) \cdot B_{s*}\mathbf{n}(0),$$

where $\theta(s)$ is the oriented angle from $\mathbf{t}(s)$ to $B_{s*}\mathbf{t}(0)$. It is easy to compute

$D'\mathbf{t}/ds$ in terms of θ : For simplicity, and without loss of generality, we assume that $f(0, 0) = 1 \in S^3$, and that $\mathbf{t}(0)$ and $\mathbf{n}(0)$ are $X_1, X_2 \in \mathcal{L}(S^3)$. Then the functions f_i in equation (3) on page 98 are just

$$f_1 = \cos \theta, \quad f_2 = -\sin \theta, \quad f_3 = 0,$$

so equation (6) on page 99 gives

$$\begin{aligned} \frac{D'\mathbf{t}}{ds} &= -\theta'(s)[\sin \theta(s) \cdot B_{s*}\mathbf{t}(0) + \cos \theta \cdot B_{s*}\mathbf{n}(0)] \\ &= -\theta'(s) \cdot \mathbf{n}(s). \end{aligned}$$

Comparing with equation (1) on page 102, we see that $\theta' = S'$; since $\theta(0) = 0$, we find that

$$S(s) = \theta(s) + S(0).$$

From this we easily see that

B_{s*} takes the tangent vector to the curve $t \mapsto f(0, t)$ at $t = 0$
to the tangent vector to the curve $t \mapsto f(s, t)$ at $t = 0$.

Moreover, these curves are asymptotic curves, so their osculating planes at $t = 0$ coincide with the osculating planes of the asymptotic curve $s \mapsto f(s, 0)$ at 0 and s , respectively. Thus their binormals at $t = 0$ are the binormals $\mathbf{b}(0)$ and $\mathbf{b}(s)$ of the curve $s \mapsto f(s, t)$. Hence

B_{s*} takes the binormal to the curve $t \mapsto f(0, t)$ at $t = 0$
to the binormal to the curve $t \mapsto f(s, t)$ at $t = 0$.

These two facts show that B_s must be the isometry A_s . So A_s is indeed a left translation.

If we write $c(s) = f(s, 0)$ and $\gamma(t) = f(0, t)$, we thus see that our surface M can be written as a collection of left translates of γ ,

$$M = \{[c(s) \cdot c(0)^{-1}] \cdot \gamma(t)\}.$$

Notice that this can equally well be written as a collection of right translates of c ,

$$\begin{aligned} M &= \{c(s) \cdot c(0)^{-1} \cdot \gamma(t)\} = \{c(s) \cdot \gamma(0)^{-1} \cdot \gamma(t)\} \\ &= \{c(s) \cdot [\gamma(0)^{-1} \cdot \gamma(t)]\}; \end{aligned}$$

naturally we could have also deduced this description directly, by considering the isometries of the curves $s \mapsto f(s, t)$, and applying the second part of Theorem 44.

Conversely, suppose we have any two curves c and γ with torsions $\tau = 1$ and $\tau = -1$, respectively. Suppose, moreover, that they are placed so that $c(0) = \gamma(0)$ and so that their osculating planes at 0 coincide. For simplicity, also assume that $c(0) = \gamma(0) = 1 \in S^3$. Then c and γ will not be tangent at 0, and we can consider the surface

$$M = \{c(s) \cdot \gamma(t)\}.$$

Applying Theorem 44 first to the curve c with $\tau = 1$, we find that the osculating plane of c at s coincides with the osculating plane of the curve $t \mapsto c(s) \cdot \gamma(t)$ at $t = 0$; hence these osculating planes coincide with the tangent space of M at $c(s)$. Now applying Theorem 44 to the curves $t \mapsto c(s) \cdot \gamma(t)$, all with torsions $\tau = -1$, we find that the tangent space of M at any point $c(s_0) \cdot \gamma(t_0)$ coincides with the osculating planes of the parameter curves $s \mapsto c(s) \cdot \gamma(t_0)$ at $s = s_0$ and $t \mapsto c(s_0) \cdot \gamma(t)$ at $t = t_0$. Thus these parameter curves are asymptotic curves. So the Beltrami-Enneper Theorem shows that M has $K_{\text{ext}} = -1$.

We can also consider the case where c has torsion $\tau = 1$, but γ is a geodesic, and hence does not have a torsion defined anywhere. The first part of our argument still shows that the tangent space of M at points $c(s)$ coincides with the osculating plane of c at s . In other words,

$$(1) \quad \frac{D'c'(s)}{ds} \text{ is a linear combination of } c'(s) \text{ and } L_{c(s)*}\gamma'(0).$$

To show that the tangent space of M at $c(s_0) \cdot \gamma(t_0)$ coincides with the osculating plane of $s \mapsto c(s) \cdot \gamma(t_0)$ at $s = s_0$, we must show that

$\left. \frac{D'}{ds} \right|_{s=s_0} R_{\gamma(t_0)*} c'(s)$ is a linear combination of $R_{\gamma(t_0)*} c'(s_0)$ and $L_{c(s_0)*} \gamma'(t_0)$.

Now we have

$$\begin{aligned} \left. \frac{D'}{ds} \right|_{s=s_0} R_{\gamma(t_0)*} c'(s) &= R_{\gamma(t_0)*} \left. \frac{D' c'(s)}{ds} \right|_{s=s_0} \\ &= \text{a linear combination of } R_{\gamma(t_0)*} c'(s_0) \\ &\quad \text{and } R_{\gamma(t_0)*} L_{c(s_0)*} \gamma'(0), \quad \text{by (1).} \end{aligned}$$

So it suffices to observe that

$$\begin{aligned} R_{\gamma(t_0)*} L_{c(s_0)*} \gamma'(0) &= L_{c(s_0)*} R_{\gamma(t_0)*} \gamma'(0) \\ &= L_{c(s_0)*} \gamma'(t_0), \end{aligned}$$

since the geodesic γ through $1 \in S^3$ is a 1-parameter subgroup, and hence the integral curve of a right invariant vector field (recall again the second proof of Corollary I.10-8; although this proof deals with left invariant vector fields, it works just as well for right invariant vector fields). So our surface $M = \{c(s) \cdot \gamma(t)\}$ again has $K_{\text{ext}} = -1$.

Finally,* suppose that c and γ are *both* (distinct) geodesics through $1 \in S^3$. Then the surface $M = \{c(s) \cdot \gamma(t)\}$ still has $K_{\text{ext}} = -1$, or $K_{\text{int}} = 0$. To see this, we consider the parameter curves

$$\begin{array}{lll} s \mapsto c(s) \cdot \gamma(t_0) & \text{with tangent vectors} & R_{\gamma(t_0)*} c'(s_0) \\ t \mapsto c(s_0) \cdot \gamma(t) & & L_{c(s_0)*} \gamma'(t_0). \end{array}$$

We note that

$$\begin{aligned} \langle R_{\gamma(t_0)*} c'(s_0), L_{c(s_0)*} \gamma'(t_0) \rangle &= \langle R_{\gamma(t_0)*} L_{c(s_0)*} c'(0), L_{c(s_0)*} R_{\gamma(t_0)*} \gamma'(0) \rangle \\ &= \langle R_{\gamma(t_0)*} L_{c(s_0)*} c'(0), R_{\gamma(t_0)*} L_{c(s_0)*} \gamma'(0) \rangle \\ &= \langle c'(0), \gamma'(0) \rangle. \end{aligned}$$

Thus our surface has two families of geodesics intersecting at a constant angle, so it is flat by Proposition 4-6. In particular, the flat torus

$$\left\{ x \in \mathbb{R}^4 : x_1^2 + x_2^2 = \frac{1}{2} \text{ and } x_3^2 + x_4^2 = \frac{1}{2} \right\}$$

*We will not consider the case where our asymptotic curves have curvature $\kappa(s) = 0$ for only certain s . The truly fanatical reader may wish to investigate this situation further.

is of this form. It is generated by the two geodesics

$$\left\{ \frac{1}{\sqrt{2}}(\cos \theta, \sin \theta, \cos \theta, \sin \theta) \right\}$$

$$\left\{ \frac{1}{2}(\cos \phi + \sin \phi, \cos \phi - \sin \phi, -\cos \phi - \sin \phi, -\cos \phi + \sin \phi) \right\},$$

of which the second lies in the plane spanned by $(1, 1, -1, -1), (1, -1, -1, 1)$ and the first in the orthogonal complement.

We now have a very general way of describing surfaces M in S^3 with $K_{\text{ext}} = -1$; we can take any “translation surface” $\{c(s) \cdot \gamma(t)\}$, where c and γ are curves of torsion 1 and -1 with $c(0) = \gamma(0) = 1 \in S^3$ and common osculating planes at 1. Since the curves c and γ are otherwise arbitrary, there are clearly a great number of such surfaces. We will describe some features of these surfaces in a little greater detail, and then indicate some open questions.

It will be very useful to introduce a famous creature of algebraic topology, the Hopf map $h: S^3 \rightarrow S^2$, which is defined as follows. We regard S^2 as the one-point compactification $\mathbb{C} \cup \{\infty\}$ of the complex numbers; the specific identification of S^2 and $\mathbb{C} \cup \{\infty\}$ will be given by means of stereographic projection, together with the identification of the north pole of S^2 with ∞ . However, we will use a slightly different version of stereographic projection. We now regard S^2 as the standard unit sphere $\{p \in \mathbb{R}^3 : |p| = 1\}$, and map a point $p \in S^2 - \{(0, 0, 1)\}$ into the intersection $\sigma(p)$ of the (x, y) -plane with the straight line between $(0, 0, 1)$ and p . It is easy to check that for our new σ we have

$$\sigma(a, b, c) = \left(\frac{a}{1-c}, \frac{b}{1-c} \right)$$

$$\sigma^{-1}(x, y) = \left(\frac{2x}{x^2 + y^2 + 1}, \frac{2y}{x^2 + y^2 + 1}, \frac{x^2 + y^2 - 1}{x^2 + y^2 + 1} \right).$$

It is not hard to see that $S^2 = \mathbb{C} \cup \{\infty\}$ has a C^∞ atlas consisting of two maps

$$\begin{aligned} f_1: \mathbb{C} &\rightarrow \mathbb{C} \\ f_2: \mathbb{C} - \{0\} \cup \{\infty\} &\rightarrow \mathbb{C} \end{aligned}$$

with $f_1 = \text{identity}$ and

$$f_2(z) = \begin{cases} \frac{1}{z}, & z \neq \infty \\ 0, & z = \infty. \end{cases}$$

We consider S^3 as

$$\{(z_1, z_2) \in \mathbb{C} \times \mathbb{C} : |z_1|^2 + |z_2|^2 = 1\}.$$

Then $h: S^3 \rightarrow S^2$ is defined by

$$h(z_1, z_2) = \frac{z_1}{z_2},$$

where “ z_1/z_2 ” = ∞ if $z_2 = 0$. This map is clearly C^∞ on the set where $z_2 \neq 0$, and also on the set where $z_1 \neq 0$, since we then have

$$\begin{aligned} f_2 \circ h(z_1, z_2) &= \begin{cases} f_2\left(\frac{z_1}{z_2}\right), & z_2 \neq 0 \\ f_2(\infty), & z_2 = 0 \end{cases} = \begin{cases} \frac{z_2}{z_1}, & z_2 \neq 0 \\ 0, & z_2 = 0 \end{cases} \\ &= \frac{z_2}{z_1}. \end{aligned}$$

The inverse image $h^{-1}(z_0)$ of any point $z_0 \in \mathbb{C}$ is

$$h^{-1}(z_0) = \{(z_1, z_2) \in S^3 : z_1 = z_0 z_2\}.$$

If $z_j = x_j + iy_j$ for $j = 0, 1, 2$, this can be written as

$$h^{-1}(z_0) = \{(x_1, y_1, x_2, y_2) \in S^3 : x_1 = x_0 x_2 - y_0 y_2 \text{ and } y_1 = x_0 y_2 + x_2 y_0\},$$

which is the intersection of S^3 with two hyperplanes through the origin. So $h^{-1}(z_0)$ is a great circle. Moreover,

$$h^{-1}(\infty) = \{(z_1, z_2) \in S^3 : z_2 = 0\}$$

is also a great circle.

Now we need to know what the orthogonal maps $A: S^2 \rightarrow S^2$ look like when we consider them as maps $\mathbb{C} \cup \{\infty\} \rightarrow \mathbb{C} \cup \{\infty\}$. Elementary complex analysis tells us that they must be maps of the form

$$f(z) = (az + b)/(cz + d),$$

for they must be one-one and have at most one pole, of order ≤ 1 (we can also use Problem 4-11 to reach the same conclusion). Some further calculations (Problem 21) show that these maps, when normalized to have $ad - bc = 1$, correspond to orthogonal maps if and only if

$$\begin{aligned} |a|^2 + |c|^2 &= 1 \\ |b|^2 + |d|^2 &= 1 \end{aligned} \quad a\bar{b} = -c\bar{d}.$$

On the other hand, if these conditions are satisfied, then the map

$$g(z_1, z_2) = (az_1 + bz_2, cz_1 + dz_2)$$

is easily seen to be an isometry of $S^3 \subset \mathbb{C} \times \mathbb{C}$. Now for any set $X \subset S^2$ we have

$$\begin{aligned} (z_1, z_2) \in h^{-1}(f^{-1}(X)) &\iff (z_1, z_2) \in S^3 \text{ and } \frac{z_1}{z_2} \in f^{-1}(X) \\ &\iff (z_1, z_2) \in S^3 \text{ and } \frac{a\frac{z_1}{z_2} + b}{c\frac{z_1}{z_2} + d} \in X \\ &\iff (z_1, z_2) \in S^3 \text{ and } \frac{az_1 + bz_2}{cz_1 + dz_2} \in X \\ &\iff (z_1, z_2) \in S^3 \text{ and } h(g(z_1, z_2)) \in X. \end{aligned}$$

Thus

$$h^{-1}(f^{-1}(X)) = g^{-1}(h^{-1}(X)).$$

In other words, if we want to know what $h^{-1}(X) \subset S^3$ looks like, up to an isometry of S^3 , we can replace $X \subset S^2$ by any set related to X by an isometry of S^2 . In particular, to find $h^{-1}(\Sigma)$ for $\Sigma \subset S^2$ a circle, we can assume that Σ is parallel to the (x, y) -plane, so that the stereographic projection of Σ in \mathbb{C} is just a circle $\{z : |z| = R\}$. Then

$$\begin{aligned} h^{-1}(\{z : |z| = R\}) &= \left\{ (z_1, z_2) : |z_1|^2 + |z_2|^2 = 1 \text{ and } \left| \frac{z_1}{z_2} \right| = R \right\} \\ &= \left\{ (z_1, z_2) : |z_1| = \frac{R}{\sqrt{1+R^2}} \text{ and } |z_2| = \frac{1}{\sqrt{1+R^2}} \right\}, \end{aligned}$$

which is just a product torus. This shows that all product tori in S^3 are made up of a family of great circles, which are consequently asymptotic curves. When $R \neq 1$, the other asymptotic curves are not great circles. If they begin at one

point of a great circle they will generally return to a different point of this great circle. This shows how a translation surface $\{c(s) \cdot \gamma(t)\}$ can be compact even though the curve c or γ may not be closed.

Now let c be any immersed curve S^3 . We claim that the surface $h^{-1}(c)$ has $K_{\text{ext}} = -1$ everywhere. In fact, for any s_0 , we can consider the osculating circle $\Sigma \subset S^2$ of c at s_0 (in other words, Σ is the circle in S^2 which is tangent to c at s_0 and whose curvature, as a curve in S^2 , is the same as the curvature $\kappa(s_0)$ of c at s_0). Then Σ and c agree up to second order at $c(s_0)$, so $h^{-1}(\Sigma)$ and $h^{-1}(c)$ agree up to second order on the whole great circle $h^{-1}(c(s_0))$; since $h^{-1}(\Sigma)$ is a flat torus, with $K_{\text{ext}} = -1$ everywhere, $h^{-1}(c)$ must also have $K_{\text{ext}} = -1$ everywhere. Taking c to be an imbedded closed curve in S^2 , we obtain an imbedded surface $h^{-1}(c)$ in S^3 , with $K_{\text{ext}} = -1$, which is homeomorphic to a torus, but generally not a product torus. A non-geodesic asymptotic curve in $h^{-1}(c)$ will be a curve \tilde{c} with $h \circ \tilde{c} = c$; it would be interesting (and probably very difficult) to determine for precisely which curves c this curve \tilde{c} is closed. In this connection, we point out that there are certainly some closed curves in S^3 of constant torsion $\tau = 1$. In fact, just as cylindrical helices in \mathbb{R}^3 have constant torsion, the helices on product tori in S^3 are easily seen to have constant torsion, and in the latter case we can arrange for the helices to be closed. I do not know whether there are closed curves c and γ in S^3 of torsion $\tau = +1$ and $\tau = -1$ such that the translation surface $\{c(s) \cdot \gamma(t)\}$ is an *imbedded* torus (the helices on product tori give only immersed tori). Nor do I know the answer to the following problem, which seems quite hard: are there one-one curves c and γ in S^3 of torsion $\tau = +1$ and $\tau = -1$ such that the translation surface $\{c(s) \cdot \gamma(t)\}$ is a *one-one* map into S^3 ? Finally, one could try to analyze the non-orientable complete surfaces in S^3 with $K_{\text{ext}} = -1$.

Now we consider the case $N = H^3$, with constant curvature -1 , so that (*) becomes

$$K_{\text{int}} = K_{\text{ext}} - 1.$$

First we see that $K_{\text{ext}} < 0 \implies K_{\text{int}} < 0$, so Theorem 41 shows that there are no complete surfaces immersed in H^3 with constant $K_{\text{ext}} < 0$. Since we also have $K_{\text{ext}} > 1 \implies K_{\text{int}} > 0$, Theorem 39 implies that a complete surface immersed in H^3 with constant $K_{\text{ext}} > 1$ is all-umbilic; since $K_{\text{int}} > 0$, it must actually be a geodesic sphere.

In the range $0 \leq K_{\text{ext}} \leq 1$ we have at least the totally geodesic spheres, the equidistant surfaces, and the horospheres, but we will find other examples also.

We consider first the upper range $K_{\text{ext}} = 1 \implies K_{\text{int}} = 0$. By considering the universal covering space of our immersed surface M with $K_{\text{int}} = 0$ we can assume that M is simply-connected. Thus M , with the induced metric, is isometric to \mathbb{R}^2 with its usual metric. Equivalently, we are considering *isometric* immersions $f: \mathbb{R}^2 \rightarrow H^3$, where \mathbb{R}^2 has its usual metric $dx \otimes dx + dy \otimes dy$, and H^3 has the metric $\langle \cdot, \cdot \rangle$ of constant curvature -1 . Let l_{ij} be the coefficients of the second fundamental form Π_f . In Gauss' equation,

$$\begin{aligned} & \langle s(X, Z), s(Y, W) \rangle - \langle s(Y, Z), s(X, W) \rangle \\ &= \langle R'(X, Y)Z, W \rangle - \langle R(X, Y)Z, W \rangle \\ &= -[\langle X, W \rangle \cdot \langle Y, Z \rangle - \langle X, Z \rangle \cdot \langle Y, W \rangle] - \langle R(X, Y)Z, W \rangle, \end{aligned}$$

we choose $X = Z = \partial/\partial x$ and $Y = W = \partial/\partial y$, to obtain

$$(1) \quad l_{11}l_{22} - (l_{12})^2 = 1.$$

In the Codazzi-Mainardi equations,

$$\begin{aligned} 0 &= (\nabla_X \Pi)(Y, Z) - (\nabla_Y \Pi)(X, Z) \\ &= X(\Pi(Y, Z)) - Y(\Pi(X, Z)) - \dots + \dots, \end{aligned}$$

we take $X = \partial/\partial x$ and $Y = \partial/\partial y$, and then $Z = \partial/\partial x$ or $\partial/\partial y$ to obtain

$$(2) \quad \frac{\partial l_{12}}{\partial x} = \frac{\partial l_{11}}{\partial y}, \quad \frac{\partial l_{22}}{\partial x} = \frac{\partial l_{12}}{\partial y}.$$

These equations imply that there are functions $\alpha, \beta: \mathbb{R}^2 \rightarrow \mathbb{R}$ with

$$\begin{array}{ll} (a) \quad \frac{\partial \alpha}{\partial y} = l_{12} & (c) \quad \frac{\partial \beta}{\partial y} = l_{22} \\ (b) \quad \frac{\partial \alpha}{\partial x} = l_{11} & (d) \quad \frac{\partial \beta}{\partial x} = l_{12}. \end{array} \quad \text{and}$$

Then (a) and (d) imply that there is a function $\phi: \mathbb{R}^2 \rightarrow \mathbb{R}$ with

$$\frac{\partial \phi}{\partial x} = \alpha \quad \text{and} \quad \frac{\partial \phi}{\partial y} = \beta.$$

Together with (b) and (c) we thus have

$$(3) \quad \frac{\partial^2 \phi}{\partial x^2} = l_{11}, \quad \frac{\partial^2 \phi}{\partial x \partial y} = l_{12}, \quad \frac{\partial^2 \phi}{\partial y^2} = l_{22}.$$

Thus equation (1) yields

$$(*) \quad \frac{\partial^2 \phi}{\partial x^2} \frac{\partial^2 \phi}{\partial y^2} - \left(\frac{\partial^2 \phi}{\partial x \partial y} \right)^2 = 1.$$

We now appeal to a strange result which is usually used in a completely different context (see Chapter 9):

45. THEOREM (JÖRGENS). If $\phi: \mathbb{R}^2 \rightarrow \mathbb{R}$ is a function on the whole plane satisfying

$$(*) \quad \frac{\partial^2 \phi}{\partial x^2} \frac{\partial^2 \phi}{\partial y^2} - \left(\frac{\partial^2 \phi}{\partial x \partial y} \right)^2 = 1,$$

then ϕ is a quadratic polynomial in x and y .

PROOF. We adopt the abbreviations

$$\begin{aligned} p &= \frac{\partial \phi}{\partial x}, & q &= \frac{\partial \phi}{\partial y} \\ r &= \frac{\partial^2 \phi}{\partial x^2}, & s &= \frac{\partial^2 \phi}{\partial x \partial y}, & t &= \frac{\partial^2 \phi}{\partial y^2}, \end{aligned}$$

so that our equation reads

$$(*) \quad rt - s^2 = 1.$$

This implies that $rt > 0$, so that r and t have the same sign. We can assume that $r, t > 0$ everywhere, by replacing ϕ by $-\phi$ if necessary.

For fixed (x_0, y_0) and (x_1, y_1) , consider the function

$$h(\tau) = \phi(x_0 + \tau(x_1 - x_0), y_0 + \tau(y_1 - y_0)).$$

We have

$$\begin{aligned} h'(\tau) &= (x_1 - x_0)p + (y_1 - y_0)q, \\ h''(\tau) &= (x_1 - x_0)^2 r + 2(x_1 - x_0)(y_1 - y_0)s + (y_1 - y_0)^2 t, \end{aligned}$$

where p, q, r, s, t are evaluated at $(x_0 + \tau(x_1 - x_0), y_0 + \tau(y_1 - y_0))$. If $x_1 = x_0$, then $h''(\tau) = (y_1 - y_0)^2 t \geq 0$. If $x_1 \neq x_0$, then

$$h''(\tau) = (x_1 - x_0)^2 \left[r - 2 \left(\frac{y_1 - y_0}{x_1 - x_0} \right) s + \left(\frac{y_1 - y_0}{x_1 - x_0} \right)^2 t \right].$$

The term in brackets is a quadratic polynomial in $(y_1 - y_0)/(x_1 - x_0)$ with discriminant $4s^2 - 4rt < 0$, by (*), so it is always positive. Thus we always have $h''(\tau) \geq 0$. This implies that

$$h'(1) \geq h'(0),$$

and thus

$$(1) \quad (x_1 - x_0)(p_1 - p_0) + (y_1 - y_0)(q_1 - q_0) \geq 0,$$

where

$$p_i = p(x_i, y_i), \quad q_i = q(x_i, y_i) \quad i = 0, 1.$$

Consider the *transformation of Lewy*:

$$T(x, y) = (\xi(x, y), \eta(x, y)) = (x + p(x, y), y + q(x, y)).$$

If we set

$$\xi_i = \xi(x_i, y_i), \quad \eta_i = \eta(x_i, y_i) \quad i = 0, 1,$$

then equation (1) implies that

$$(\xi_1 - \xi_0)^2 + (\eta_1 - \eta_0)^2 \geq (x_1 - x_0)^2 + (y_1 - y_0)^2.$$

Hence $T: \mathbb{R}^2 \rightarrow \mathbb{R}^2$ is distance-increasing, and, in particular, T is one-one. Moreover, the Jacobian of T is

$$\begin{pmatrix} \frac{\partial \xi}{\partial x} & \frac{\partial \xi}{\partial y} \\ \frac{\partial \eta}{\partial x} & \frac{\partial \eta}{\partial y} \end{pmatrix} = \begin{pmatrix} 1 + r & s \\ s & 1 + t \end{pmatrix},$$

with determinant

$$\begin{aligned} 1 + r + t + rt - s^2 &= 2 + r + t \quad \text{by } (*) \\ &\geq 2, \end{aligned}$$

so T is an immersion, and image T is open. But image T is also closed: For if $T(x_i, y_i) \rightarrow \alpha \in \mathbb{R}^2$, so that $\{T(x_i, y_i)\}$ is a Cauchy sequence, then $\{(x_i, y_i)\}$ is also a Cauchy sequence, since T is distance-increasing; thus $(x_i, y_i) \rightarrow \beta \in \mathbb{R}^2$, and $T(\beta) = \alpha$. So T is actually a diffeomorphism of \mathbb{R}^2 onto itself. It will be convenient to use classical ambiguous notation and denote the inverse map T^{-1} by $(\xi, \eta) \mapsto (x(\xi, \eta), y(\xi, \eta))$. Its Jacobian is

$$\begin{aligned} \begin{pmatrix} \frac{\partial x}{\partial \xi} & \frac{\partial x}{\partial \eta} \\ \frac{\partial y}{\partial \xi} & \frac{\partial y}{\partial \eta} \end{pmatrix} &= \begin{pmatrix} 1+r & s \\ s & 1+t \end{pmatrix}^{-1} \\ &= \frac{1}{2+r+t} \begin{pmatrix} 1+t & -s \\ -s & 1+r \end{pmatrix}, \end{aligned}$$

from which we can read off the partial derivatives of x and y .

Now define $F: \mathbb{R}^2 \rightarrow \mathbb{R}^2$ by

$$\begin{aligned} F(\xi, \eta) &= (U(\xi, \eta), V(\xi, \eta)) \\ &= (x - p, -y + q) \quad \text{i.e.,} \\ &= (x(\xi, \eta) - p(x(\xi, \eta), y(\xi, \eta)), -y(\xi, \eta) + q(x(\xi, \eta), y(\xi, \eta))). \end{aligned}$$

Then

$$\begin{aligned} \frac{\partial U}{\partial \xi} &= \frac{\partial x}{\partial \xi} - \frac{\partial p}{\partial x} \frac{\partial x}{\partial \xi} - \frac{\partial p}{\partial y} \frac{\partial y}{\partial \xi} \\ &= \frac{1}{2+r+t} [1+t - r(1+t) - s(-s)] \\ &= \frac{t-r}{2+r+t}. \end{aligned}$$

Similarly, we find that

$$\frac{\partial V}{\partial \eta} = \frac{t-r}{2+r+t} = \frac{\partial U}{\partial \xi}$$

and

$$\frac{\partial V}{\partial \xi} = \frac{2s}{2+r+t} = -\frac{\partial U}{\partial \eta}.$$

Thus (U, V) satisfies the Cauchy-Riemann equations, so the map $F: \mathbb{C} \rightarrow \mathbb{C}$ defined by

$$\begin{aligned} F(\xi + i\eta) &= U(\xi, \eta) + iV(\xi, \eta) \\ &= x - p + (-y + q)i \end{aligned}$$

is complex analytic, and for the complex derivative F' we have

$$\begin{aligned} (2) \quad F'(\xi + i\eta) &= \frac{\partial U}{\partial \xi} + i \frac{\partial V}{\partial \xi} \\ &= \frac{t - r + 2is}{2 + r + t}. \end{aligned}$$

Consequently,

$$\begin{aligned} |F'(\xi + i\eta)|^2 &= \frac{(t - r)^2 + 4s^2}{(2 + r + t)^2} \\ &= \frac{(t - r)^2 + 4rt - 4}{(2 + r + t)^2} \quad \text{by } (*) \\ &= \frac{(t + r)^2 - 4}{(2 + r + t)^2} = \frac{-2 + r + t}{2 + r + t}, \end{aligned}$$

which gives

$$(3) \quad 1 - |F'(\xi + i\eta)|^2 = \frac{4}{2 + r + t} > 0.$$

Thus F' is bounded, and consequently constant, by Liouville's theorem. But equations (2) and (3) allow us to solve for r, s, t in terms of F' (here Re and Im represent the real and imaginary parts):

$$\begin{aligned} s &= \frac{2 + r + t}{2} \cdot \text{Im } F' = \frac{2 \cdot \text{Im } F'}{1 - |F'|^2} \\ \left. \begin{aligned} t - r &= \frac{4 \text{Re } F'}{1 - |F'|^2} \\ t + r &= \frac{4}{1 - |F'|^2} - 2 \end{aligned} \right\} \Rightarrow \begin{aligned} t &= \frac{1}{2} \left(\frac{4 \text{Re } F'}{1 - |F'|^2} + \frac{4}{1 - |F'|^2} - 2 \right) \\ r &= \frac{1}{2} \left(\frac{4}{1 - |F'|^2} - 2 - \frac{4 \text{Re } F'}{1 - |F'|^2} \right). \end{aligned}$$

Since F' is constant, so are r, s, t . ♦

Applying Jörgens' Theorem to our ϕ , we find that the l_{ij} are *constants*. We can assume, moreover, that $l_{12} = 0$, by means of an orthogonal transformation of \mathbb{R}^2 . Then $l_{11} = k_1$ and $l_{22} = k_2$ are the principal curvatures of the immersed surface $f(\mathbb{R}^2)$, and $k_1 k_2 = 1$. By Theorem 21, the immersion f is determined, up to an isometry of H^3 , by the pair $\{k_1, k_2\}$, with $k_1, k_2 > 0$. So in order to determine all such f , we just have to find one for each pair $\{k_1, k_2\}$ with $k_1 k_2 = 1$. For $k_1 = k_2 = 1$, all points are umbilics, and f must be a horosphere. To describe the other examples, consider the upper half-space model \mathcal{H}^3 . Our immersed surface $M \subset \mathcal{H}^3$ with constant k_1, k_2 must have isometries of \mathcal{H}^3 taking any point to any other. Now one simple case of isometries of \mathcal{H}^3 are the inversions with respect to a sphere around 0. These isometries take rays through 0 into themselves, and thus take cones through 0 into themselves. Moreover, if

we consider only right circular cones, then there are clearly isometries of \mathcal{H}^3 taking any point on a circle parallel to the (x, y) -plane to any other point on this circle, and hence there are isometries of \mathcal{H}^3 taking any point on the cone to any other point. These cones thus have constant k_1, k_2 . A simple calculation shows, in fact, that if the generators of the cone make an angle of θ with the z -axis, then the principal curvature k_1 for the principal vectors pointing along the generators is

$$k_1 = \sin \theta,$$

while the principal curvature k_2 for the principal vectors pointing along the circles parallel to the (x, y) -plane is

$$k_2 = \frac{1}{\sin \theta}.$$

Thus $k_1 k_2 = 1$, and all pairs (k_1, k_2) are accounted for. We note, finally, that by the discussion on pages 14–15, our cone is the set of points at a fixed distance from the z -axis. We thus have

46. THEOREM (VOLKOV AND VLADIMIROVA; SASAKI). A complete surface in H^3 with constant $K_{\text{ext}} = 1$ is either a horosphere or the set of points at a fixed distance from a geodesic.

Next we consider the lower range $K_{\text{ext}} = 0 \implies K_{\text{int}} = -1$. We have already indicated that there are many complete surfaces $M \subset H^3$ with $K_{\text{ext}} = 0$, but now we will look more closely at their topological type. We know that if $B \subset \mathbb{R}^3$ is the projective model of H^3 (so B is the unit ball with a metric of constant curvature -1 whose geodesics are reparameterized straight lines of \mathbb{R}^3), then a surface $M \subset B$ has $K_{\text{int}} = -1$ if and only if M is flat, considered as a surface in \mathbb{R}^3 with the usual metric. Consider the intersection of a plane with B , and a portion P of this plane which is bounded by four non-intersecting geodesics $\gamma_1, \dots, \gamma_4$. The geodesics γ_1 and γ_3 can be joined by a cylinder Z ,

and similarly γ_2 and γ_4 can be joined by a disjoint cylinder Z' . By choosing appropriate profile curves for these cylinders we can make a smooth surface $P \cup Z \cup Z'$, and it will have $K_{\text{int}} = -1$ everywhere. The resulting surface is topologically equivalent to a torus minus a disc (or a torus minus a point).

More generally, we can begin with portions P that are bounded by $2g$ non-intersecting geodesics. In this way we can obtain surfaces homeomorphic to any compact surface with a point deleted.

Notice that this construction produces only C^∞ surfaces, not analytic ones. It seems to me that all *analytic* flat surfaces in \mathbb{R}^3 , and *a posteriori* all complete analytic surfaces in B with $K_{\text{int}} = -1$, must be homeomorphic to a plane, cylinder, or Möbius strip; but I haven't tried to make a rigorous proof. If this does indeed turn out to be the case, it will be one of the rare instances where the requirements of smoothness and analyticity lead to different geometric conclusions.

We are still left with the complete surfaces in H^3 with $0 < K_{\text{ext}} < 1$. We can obtain infinitely many examples of such surfaces by looking at surfaces of revolution.

Given a geodesic γ in the hyperbolic plane, we can describe a complete arc-length parameterized curve $s \mapsto c(s)$ in the hyperbolic plane in terms of the distance $r(s)$ from $c(s)$ to γ . A curve c can be found with a given function r

provided that $|r'| \leq 1$, so that $|r(s_1) - r(s_0)| \leq s_1 - s_0$. If we rotate c around γ in hyperbolic 3-space, then the first fundamental form of our surface is (Problem 22)

$$I = \sinh^2 r(s) d\theta \otimes d\theta + ds \otimes ds,$$

and we compute that its intrinsic curvature is

$$K_{\text{int}} = -\frac{1}{\sinh r(s)} \cdot \frac{d^2 \sinh r(s)}{ds^2}.$$

Setting $K_{\text{int}} = -c^2$, we obtain the strictly positive solution

$$\sinh r(s) = e^{cs}, \quad \text{as well as} \quad \sinh r(s) = a \cosh(cs), \quad a > 0.$$

Both solutions satisfy $|r'| < 1$ for $0 < c < 1$. Thus for each $K_{\text{ext}} = 1 - c^2$ with $0 < K_{\text{ext}} < 1$ we obtain a 1-parameter family of distinct surfaces, and

one extra one. In the model $(B^3, \langle \cdot, \cdot \rangle)$ these surfaces look like those below. I do

not know whether these are the only surfaces with $0 < K_{\text{ext}} < 1$, as in the case of surfaces with $K_{\text{ext}} = 1$, or if there are many others, as in the case $K_{\text{ext}} = 0$.

G. HYPERSURFACES OF CONSTANT CURVATURE IN HIGHER DIMENSIONS

We now want to consider hypersurfaces $M^n \subset N^{n+1}$, where $(N, \langle \cdot, \cdot \rangle)$ is a manifold of constant curvature K_0 and of dimension > 3 . We are interested in the hypersurfaces M of constant curvature; since M is no longer a surface, there is no ambiguity of meaning here—we are requiring that M , with the induced metric, have all sectional curvatures equal. After the exertions of the last section, it is a relief to find that everything is now much *easier*, and most of the results are essentially *local*. For example, we claim that there is no 3-dimensional manifold $M \subset \mathbb{R}^4$ with constant curvature -1 , not even a non-complete one. In fact, if M has principal curvatures k_1, k_2, k_3 at p , then all products $k_i k_j$ must $= -1$, which is clearly impossible, since at least two of the k_i will have the same sign. More generally,

47. THEOREM. For $n > 2$, let N^{n+1} be a manifold of constant curvature K_0 , and let $M^n \subset N^{n+1}$ be a hypersurface of constant curvature K . Then $K \geq K_0$. If $K > K_0$, then all points of M are umbilics, and if $K = K_0$, then at most one principal curvature is non-zero.

PROOF. Let k_1, \dots, k_n be the principal curvatures at p . Gauss' equation shows that

$$K - K_0 = k_i k_j, \quad i \neq j.$$

If $K = K_0$, then $k_i k_j = 0$ for all $i \neq j$, so if k_1 , say, is $\neq 0$, then $k_2, \dots, k_n = 0$. If $K - K_0 \neq 0$, then all $k_i \neq 0$, so the equation

$$k_1 k_i = k_1 k_j \quad i, j \neq 1$$

implies that $k_2 = \dots = k_n$. Similarly, $k_1 = \dots = k_{n-1}$. Since $n > 2$, this implies that $k_1 = \dots = k_n$. So all points are umbilics. Moreover, $K - K_0 = k_1 k_2 = (k_1)^2 > 0$. ♦

We will examine the case $K = K_0$ in more detail later on. But first we indicate how more general results can be obtained by considering a certain covariant tensor of order 2, the **Ricci tensor** Ric of M . The map $\text{Ric}(p): M_p \times M_p \rightarrow \mathbb{R}$ is defined by

$$\text{Ric}(p)(X_1, X_2) = \text{trace } Y \mapsto R(X_2, Y)X_1 \quad Y \in M_p.$$

In terms of the components R^i_{jkl} of R in a coordinate system x^1, \dots, x^n , the tensor Ric is given by

$$\text{Ric} = \sum_{j,k=1}^n \text{Ric}_{jk} dx^j \otimes dx^k \quad \text{for} \quad \text{Ric}_{jk} = \sum_{i=1}^n R^i_{jki};$$

thus Ric is obtained from R by contraction. If X_1, \dots, X_n is an orthonormal basis for M_p , then $\text{Ric}(X_1, X_1)$ is the trace of the matrix $(\langle R(X_1, X_i)X_1, X_j \rangle)$. Therefore

$$\begin{aligned} \text{Ric}(X_1, X_1) &= \sum_{i=1}^n \langle R(X_1, X_i)X_1, X_i \rangle \\ &= - \sum_{i=2}^n \langle R(X_i, X_1)X_1, X_i \rangle. \end{aligned}$$

So if $X \in M_p$ is any unit vector, then $-\text{Ric}(X, X)$ is the sum of the sectional curvatures determined by X and any $n-1$ orthonormal vectors orthogonal to X . (We have defined Ric so that it agrees with the classical definition $\text{Ric}_{jk} = \sum_i R^i_{jki}$; nowadays, the opposite sign is often used.) The following result is analogous to Schur's Theorem (II.7-19).

48. **THEOREM.** If M is a connected Riemannian manifold of dimension $n \geq 3$ and

$$\text{Ric}(X, Y) = \lambda \langle X, Y \rangle$$

for some function λ on M , then λ is constant.

PROOF. Bianchi's second identity (II.5-9), together with Ricci's Lemma, gives

$$(1) \quad 0 = R_{hijk;l} + R_{hikl;j} + R_{hilj;k} = 0.$$

Multiply by $\sum_{h,i,j,k} g^{hj} g^{ik}$. We have

$$\begin{aligned}
\sum g^{hj} g^{ik} R_{hijk;l} &= - \sum g^{hj} g^{ik} R_{ihjk;l} = - \sum_{h,j} g^{hj} \sum_k R^k_{hjk;l} \\
&= - \sum_{h,j} (g^{hj} \text{Ric}_{hj})_{;l} = - \sum_{h,j} (g^{hj} g_{hj} \lambda)_{;l} \\
&= -n \frac{\partial \lambda}{\partial x^l}, \\
\sum g^{hj} g^{ik} R_{hikl;j} &= \sum g^{hj} g^{ik} R_{ihlk;j} = \sum_{h,j} g^{hj} \sum_k R^k_{hik;j} \\
&= \sum_{h,j} (g^{hj} \text{Ric}_{hl})_{;j} = \sum_{h,j} (g^{hj} g_{hl} \lambda)_{;j} \\
&= \frac{\partial \lambda}{\partial x^l}, \\
\sum g^{ik} g^{hj} R_{hilj;k} &= \sum g^{ik} g^{hj} R_{jljh;k} = \sum_{i,k} g^{ik} \sum_h R^h_{lih;k} \\
&= \sum_{i,k} (g^{ik} \text{Ric}_{li})_{;k} = \sum_{i,k} (g^{ik} g_{li} \lambda)_{;k} \\
&= \frac{\partial \lambda}{\partial x^l}.
\end{aligned}$$

So (I) becomes

$$(n-2) \frac{\partial \lambda}{\partial x^l} = 0.$$

Since $n > 2$, we have $\partial \lambda / \partial x^l = 0$ for all l . ♦

A Riemannian manifold M with $\text{Ric} = -\lambda \langle \cdot, \cdot \rangle$ is called an **Einstein space**, and λ is sometimes called its **mean curvature** (not to be confused with the mean curvature H of a submanifold). If M has constant curvature K , then M is an Einstein space with mean curvature $\lambda = (n-1)K$. We note in passing that

49. THEOREM. A connected 3-dimensional Einstein space is a manifold of constant curvature.

PROOF. Choose an orthonormal basis $X_1, X_2, X_3 \in M_p$, and let $K_{ij} = K_{ji}$ be the sectional curvature of the 2-dimensional subspace of M_p spanned by X_i and X_j . Then

$$\begin{aligned}
-\text{Ric}(X_1, X_1) &= K_{12} + K_{13} \\
-\text{Ric}(X_2, X_2) &= K_{21} + K_{23} \\
-\text{Ric}(X_3, X_3) &= K_{31} + K_{32}.
\end{aligned}$$

Hence

$$-\text{Ric}(X_1, X_1) - \text{Ric}(X_2, X_2) + \text{Ric}(X_3, X_3) = 2K_{12}.$$

Since all $\text{Ric}(X_i, X_i) = -\lambda$, we have $K_{12} = \lambda/2$. ♦

Now for a manifold $(N^{n+1}, \langle \cdot, \cdot \rangle)$ of constant curvature K_0 we consider hypersurfaces $M \subset N$ which are Einstein spaces.

50. THEOREM. For $n > 2$, let N^{n+1} be a manifold of constant curvature K_0 , and let $M^n \subset N^{n+1}$ be a hypersurface which is an Einstein space with $\text{Ric} = -\lambda \langle \cdot, \cdot \rangle$. If $\lambda > (n-1)K_0$, then all points of M are umbilics, and M is a manifold of constant curvature $K > K_0$. If $\lambda = (n-1)K_0$, then at most one principal curvature is non-zero, and M is a manifold of constant curvature K_0 .

PROOF. Let $X_1, \dots, X_n \in M_p$ be principal directions with corresponding principal curvatures k_1, \dots, k_n . Gauss' equation gives

$$(1) \quad K_{ij} = k_i k_j + K_0,$$

where K_{ij} is the sectional curvature of the subspace of M_p spanned by X_i and X_j . Then

$$\begin{aligned} \lambda &= \sum_{j \neq i} K_{ij} = \sum_{j \neq i} k_i k_j + (n-1)K_0 \\ &= \left(\sum_j k_j \right) k_i - (k_i)^2 + (n-1)K_0. \end{aligned}$$

Hence all principal curvatures k_i satisfy the equation

$$(*) \quad x^2 - \left(\sum_j k_j \right) x + [\lambda - (n-1)K_0] = 0.$$

If $\lambda = (n-1)K_0$, then every k_i is either 0 or the number $\sum_j k_j$. So there can clearly be only one $k_i \neq 0$. Then equation (1) shows that all K_{ij} equal K_0 , so that M is a manifold of constant curvature K_0 .

If $\lambda > (n-1)K_0$, then all k_i are one of the two roots α, β of (*), where

$$(2) \quad \alpha\beta = \lambda - (n-1)K_0 > 0$$

$$(3) \quad \alpha + \beta = \sum_j k_j.$$

If p of the k_i equal α , and the other $q = n - p$ of the k_i equal β , then equation (3) can be written

$$\alpha + \beta = p\alpha + q\beta \implies (p - 1)\alpha + (q - 1)\beta = 0.$$

But α and β have the same sign, by (2), so either $p - 1$ or $q - 1$ is negative, which means that either p or q is zero. Thus all k_i are equal. Then equation (1) shows that all K_{ij} equal $K_0 + (k_1)^2 > K_0$, so that M is a manifold of constant curvature $K > K_0$. ♦

Theorem 50 is not the best that can be obtained, for it is also known that if $\lambda < (n - 1)K_0$, then K_0 must be > 0 , and that in this case M must be one of a certain special class of hypersurfaces, with $\lambda = (n - 2)K_0$. For the proof of this, the reader is referred to the original paper of Fialkow [1]; see also Ryan [1].

We now consider the critical case of an immersion $f : M^n \rightarrow N^{n+1}$, where M and N have the same constant curvature K_0 , so that at most one principal curvature of $f(M)$ is non-zero at each point. If all principal curvatures are zero everywhere, so that the second fundamental form $s = 0$, then M is totally geodesic. Otherwise, we can consider the non-empty open set $U \subset M$ defined by

$$U = \{p \in M : s \neq 0 \text{ at } p\}.$$

Around any point $p \in U$, we choose an adapted orthonormal moving frame

$$X_1, \dots, X_{n-1}, X_n, X_{n+1}$$

such that X_1, \dots, X_{n-1} are principal vectors with principal curvatures 0, and X_n is a principal vector with non-zero principal curvature λ . [Our moving frame is really defined in a neighborhood of $f(p) \in N$, but for simplicity we will regard $M \subset N$ for all local arguments.] Let $\phi^\alpha, \psi_\beta^\alpha$ be the forms for this moving frame, and let θ^i, ω_j^i be the forms for X_1, \dots, X_n . Then we have

$$(1) \quad \psi_i^{n+1} = 0 \quad i = 1, \dots, n - 1$$

$$(2) \quad \psi_n^{n+1} = -\lambda\theta^n.$$

For $i = 1, \dots, n - 1$, the Codazzi-Mainardi equations give

$$0 = d\psi_i^{n+1} = \Psi_i^{n+1} - \sum_{j=1}^n \psi_j^{n+1} \wedge \omega_i^j = \Psi_i^{n+1} + \lambda\theta^n \wedge \omega_i^n.$$

Since $\Psi_i^{n+1}(X, Y) = 0$ for X, Y tangent to M , we find that $\theta^n \wedge \omega_i^n = 0$, or

$$(3) \quad \omega_i^n \text{ is a multiple of } \theta^n \text{ (on } U) \quad i = 1, \dots, n - 1.$$

From this we derive a higher dimensional analogue of Proposition 5-4.

51. PROPOSITION. The distribution Δ on $U \subset M$ defined by

$$\begin{aligned}\Delta(p) &= \{X \in M_p : s(X, Y) = 0 \text{ for all } Y \in M_p\} \\ &= \{X \in M_p : X \text{ is a principal vector with principal curvature } 0\}\end{aligned}$$

is integrable. Every integral manifold of Δ is a totally geodesic submanifold of M , and is immersed as a totally geodesic submanifold in N .

PROOF. Locally Δ is defined by $d\theta^1 = \cdots = d\theta^{n-1} = 0$. Now on U we have

$$d\theta^i = - \sum_{j=1}^n \omega_j^i \wedge \theta^j = - \sum_{j=1}^{n-1} \omega_j^i \wedge \theta^j \quad \text{by (3).}$$

So Proposition I.7-14 shows that Δ is integrable; the vector fields X_1, \dots, X_{n-1} are tangent along an integral manifold M_1 of Δ . Equation (3) says that

$$0 = \omega_i^n(X_j) = \langle \nabla'_{X_j} X_i, X_n \rangle \quad i, j \leq n-1,$$

i.e., that the second fundamental form of M_1 in M is zero. Since we also have

$$\langle \nabla'_{X_j} X_i, X_{n+1} \rangle = 0 \quad i, j \leq n-1$$

by the definition of Δ , it follows that M_1 is totally geodesic in N . ♦

Now we want to study the function λ along a geodesic γ lying in an integral manifold M_1 of Δ .

52. LEMMA. Let γ be an arclength parameterized geodesic in an integral manifold M_1 of Δ , and let $\lambda(s)$ be the value of the non-zero principal curvature at $\gamma(s)$. Then the function $\lambda(s)$ satisfies the differential equation

$$\left(\frac{1}{\lambda}\right)'' = -\frac{K_0}{\lambda}.$$

PROOF. Choose the moving frame so that γ is an integral curve of X_1 . Equations (2) and (3) imply that there are g_i with

$$(3') \quad \omega_i^n = g_i \psi_n^{n+1}.$$

The Codazzi-Mainardi equation for $i = n$ gives

$$\begin{aligned}(4) \quad d\psi_n^{n+1} &= \Psi_n^{n+1} - \sum_{j=1}^n \psi_j^{n+1} \wedge \omega_n^j \\ &= \Psi_n^{n+1}, \quad \text{by (1).}\end{aligned}$$

Thus

$$\begin{aligned}\Psi_n^{n+1} &= d\psi_n^{n+1} = -d\lambda \wedge \theta^n - \lambda d\theta^n \quad \text{by (2)} \\ &= -d\lambda \wedge \theta^n + \lambda \sum_{i=1}^n \omega_i^n \wedge \theta^i,\end{aligned}$$

and therefore

$$d\lambda \wedge \theta^n = -\lambda \sum_{i=1}^n \theta^i \wedge \omega_i^n - \Psi_n^{n+1}.$$

Applying this to (X_1, X_n) gives

$$\begin{aligned}X_1(\lambda) &= -\lambda \omega_1^n(X_n) + \lambda \omega_1^n(X_1) \\ &= -\lambda \omega_1^n(X_n) \quad \text{by (3)} \\ &= -\lambda g_1 \psi_n^{n+1}(X_n) \quad \text{by (3')} \\ &= \lambda^2 g_1 \quad \text{by (2),}\end{aligned}$$

which we can also write as

$$(*) \quad X_1 \left(\frac{1}{\lambda} \right) = -g_1.$$

Now on M we have the structural equation

$$d\omega_1^n = -\sum_{k=1}^{n-1} \omega_k^n \wedge \omega_1^k + \Omega_1^n,$$

which by (3') becomes

$$d(g_1 \psi_n^{n+1}) = -\sum_{k=1}^{n-1} g_k \psi_n^{n+1} \wedge \omega_1^k + \Omega_1^n,$$

and thus by (2) and (4)

$$dg_1 \wedge \psi_n^{n+1} + g_1 \Psi_n^{n+1} = -\lambda \left(\sum_{k=1}^{n-1} g_k \omega_1^k \right) \wedge \theta^n + \Omega_1^n.$$

Finally, we use (2) again to write our equation as

$$-\lambda dg_1 \wedge \theta^n + g_1 \Psi_n^{n+1} = -\lambda \left(\sum_{k=1}^{n-1} g_k \omega_1^k \right) \wedge \theta^n + \Omega_1^n.$$

Applying this to (X_1, X_n) we get

$$-\lambda X_1(g_1) + 0 = 0 - K_0,$$

since all $\omega_1^k(X_1) = 0$. Thus (*) yields

$$X_1 \left(X_1 \left(\frac{1}{\lambda} \right) \right) = X_1(-g_1) = -\frac{K_0}{\lambda}. \quad \blacklozenge$$

The solutions of the equation $(1/\lambda)'' = -K_0(1/\lambda)$ can be found explicitly— $1/\lambda$ is linear if $K_0 = 0$, a linear combination of \sin and \cos if $K_0 > 0$, and a linear combination of \sinh and \cosh if $K_0 < 0$. In any case, $1/\lambda$ is bounded on any bounded interval.

53. COROLLARY. If M is complete, then the integral manifolds of Δ are complete.

PROOF. We just have to show that a geodesic of an integral manifold M_1 cannot approach a boundary point of U . The argument is almost the same as that in the proof of Corollary 5-6. ♦

It is now a straightforward matter to generalize Theorem 5-9. We will make things easy for ourselves by choosing the simplest proof.

54. THEOREM. If M is a complete flat n -manifold and $f: M \rightarrow \mathbb{R}^{n+1}$ is an isometric immersion, then $f(M)$ is a generalized cylinder (it is congruent to a set of the form $\gamma \times \mathbb{R}^{n-1}$ for some curve $\gamma \subset \mathbb{R}^2$).

PROOF. We can assume M is simply connected, and thus \mathbb{R}^n . If $f(M)$ is not totally geodesic, then the set $U \subset M$ is non-empty, so by Corollary 53 some hyperplane of M is mapped isometrically onto an $(n-1)$ -dimensional plane of \mathbb{R}^{n+1} . Now apply the third proof of Theorem 5-9. ♦

We also obtain complete information for the case $K_0 > 0$.

55. THEOREM. If M^n is a complete manifold of constant curvature 1 and $f: M^n \rightarrow S^{n+1}$ is an isometric immersion, then $f(M)$ is a great n -sphere in S^{n+1} .

PROOF. We can assume M is simply connected, and thus S^n . If $f(M)$ were not totally geodesic, then the set $U \subset M$ would be non-empty, so Corollary 53 would show that there are two *disjoint* complete totally geodesic $(n-1)$ -dimensional submanifolds of $M = S^n$. This is impossible. ♦

In the case $K_0 < 0$ we would not expect such good results, since even the case $n = 2$ is so complicated. Actually, the case $n = 2$ already contains essentially all the complexity there is, for one can show that if M^n is a complete manifold

of constant curvature -1 in H^{n+1} , then the higher dimensional cohomology vanishes,

$$H^i(M) = 0 \quad \text{for } i > 1.$$

This is essentially a consequence of the analysis already provided, although technical details are required for a rigorous proof (see O'Neil [1]).

ADDENDUM 1

THE LAPLACIAN

The material of these first 3 Addenda is essentially a part of intrinsic Riemannian geometry, and might thus seem out of place in this chapter. But I felt it was appropriate to put it here since this is the first time in a long while that we have seriously considered higher dimensional Riemannian manifolds. Moreover, the next chapter will be devoted to material which is completely intrinsic in nature. Finally, some of the material covered here will be used when we return to the study of extrinsic geometry in Chapter 9.

In classical “vector analysis”, there are three operators which play a crucial role. First of all, for every smooth function $f : \mathbb{R}^n \rightarrow \mathbb{R}$ we have a vector field, the gradient of f , defined by

$$\text{grad } f = \left(\frac{\partial f}{\partial x^1}, \dots, \frac{\partial f}{\partial x^n} \right) = \sum_{i=1}^n \frac{\partial f}{\partial x^i} \cdot \frac{\partial}{\partial x^i}.$$

On the other hand, for every vector field X on \mathbb{R}^n , with

$$X = \sum_{i=1}^n a^i \frac{\partial}{\partial x^i},$$

we have a function, the divergence of X , defined by

$$\text{div } X = \sum_{i=1}^n \frac{\partial a_i}{\partial x^i}.$$

Finally, the Laplacian of f is the function*

$$\Delta f = \text{div}(\text{grad } f) = \sum_{i=1}^n \frac{\partial^2 f}{\partial (x^i)^2}.$$

* Classically, one introduced the operator $\nabla = \sum_i \frac{\partial}{\partial x^i} \cdot e_i$, where $e_i = \partial/\partial x^i$ is the i^{th} basis vector of \mathbb{R}^n , and wrote (formally)

$$\begin{aligned} \text{grad } f &= \nabla f \\ \text{div } X &= \langle \nabla, X \rangle = \nabla \cdot X \\ \Delta f &= \langle \nabla, \nabla f \rangle = \nabla \cdot \nabla f. \end{aligned}$$

For this reason Δ was often denoted by ∇^2 .

The operators grad, div, and Δ all have natural generalizations to an arbitrary Riemannian manifold $(M, \langle \cdot, \cdot \rangle)$. Consider first the gradient of f . Notice that the components of grad f on \mathbb{R}^n are just the coefficients of df in the expression $df = \sum_i (\partial f / \partial x^i) dx^i$. Consequently,

$$\left\langle \text{grad } f, \sum_{i=1}^n b^i \frac{\partial}{\partial x^i} \right\rangle = \sum_{i=1}^n \frac{\partial f}{\partial x^i} b^i = df \left(\sum_{i=1}^n b^i \frac{\partial}{\partial x^i} \right).$$

We can use this equation in any Riemannian manifold $(M, \langle \cdot, \cdot \rangle)$ to define grad f as the unique vector field such that

$$(I) \quad \langle \text{grad } f, Y \rangle = df(Y) = Y(f),$$

for all vector fields Y on M . We easily see that

$$(I) \quad \text{grad}(fg) = f \cdot \text{grad } g + g \cdot \text{grad } f.$$

In terms of a coordinate system x^1, \dots, x^n on M we have

$$\text{grad } f = \sum_{i=1}^n \left(\sum_{j=1}^n g^{ij} \frac{\partial f}{\partial x^j} \cdot \frac{\partial}{\partial x^i} \right).$$

The divergence of a vector field X on M may be defined as

$$(II) \quad (\text{div } X)(p) = \text{trace } Y \mapsto \nabla_Y X \quad Y \in M_p$$

$$= \sum_{i=1}^n \langle \nabla_{Y_i} X, Y_i \rangle \quad Y_1, \dots, Y_n \in M_p \text{ orthonormal.}$$

This clearly coincides with the original definition in Euclidean space. It is easy to check that

$$(2) \quad \text{div}(fX) = X(f) + f \cdot \text{div } X = df(X) + f \cdot \text{div } X.$$

In terms of a coordinate system x^1, \dots, x^n we have

$$X = \sum_{i=1}^n a^i \frac{\partial}{\partial x^i} \implies \text{div } X = \sum_{i=1}^n a^i_{;i} = \sum_{i=1}^n \left(\frac{\partial a^i}{\partial x^i} + \sum_{j=1}^n a^j \Gamma_{ji}^i \right).$$

We can also define div ω when ω is a 1-form, for the connection ∇ on vector fields gives rise to a connection ∇ on 1-forms (Chapter II.6), and we can set

$$(III) \quad (\text{div } \omega)(p) = \sum_{i=1}^n (\nabla_{X_i} \omega)(X_i) \quad X_1, \dots, X_n \in M_p \text{ orthonormal.}$$

It is easily checked that this definition does not depend on the choice of the orthonormal basis X_1, \dots, X_n , but we can also give a completely invariant definition. We note that every bilinear map $\alpha: V \times V \rightarrow \mathbb{R}$ gives rise to a map $\alpha': V \rightarrow V^*$ by $\alpha'(v)(w) = \alpha(v, w)$. If we also have an inner product on V , then we have an isomorphism $V^* \rightarrow V$, and thus we obtain a linear map

$$V \xrightarrow{\alpha'} V^* \rightarrow V.$$

It is easily seen that the trace of this composition is the same as

$$\sum_{i=1}^n \alpha(X_i, X_i) \quad X_1, \dots, X_n \text{ an orthonormal basis for } V.$$

To apply this to the case at hand, we consider the tensor $\nabla\omega$, with

$$(\nabla\omega)(X, Y) = (\nabla_X\omega)(Y).$$

Then

$$(\operatorname{div} \omega)(p) = \text{trace of the composition } M_p \xrightarrow{(\nabla\omega)'} M_p^* \rightarrow M_p,$$

where the isomorphism $M_p^* \rightarrow M_p$ comes from the metric. The analogue of equation (2) is

$$(3) \quad \operatorname{div}(f\omega) = \langle df, \omega \rangle + f \operatorname{div} \omega,$$

where the inner product $\langle \cdot, \cdot \rangle$ on M_p^* comes from the inner product $\langle \cdot, \cdot \rangle$ on M_p in the standard way.

More generally, consider a tensor A which is covariant of order k . We define $\operatorname{div} A$ to be a covariant tensor of order $k - 1$ by the (admittedly asymmetric) formula

$$(III') \quad \operatorname{div} A(p)(Y_2, \dots, Y_k) = \sum_{i=1}^n (\nabla_{X_i} A)(X_i, Y_2, \dots, Y_k) \\ X_1, \dots, X_n \text{ orthonormal in } M_p.$$

The reader may easily work out a completely invariant definition.

In Problem I.9-13 we introduced the Divergence Theorem for n -dimensional submanifolds-with-boundary of \mathbb{R}^n . Now that we have generalized the definition of div , we would like to generalize this theorem also. An examination of the proof hinted at in that problem leads us to hope that the following alternative definition of div is valid (the symbol \sqcup is defined in Problem I.7-4).

56. LEMMA. Let M be an oriented n -dimensional Riemannian manifold, with volume element dV (which can be considered to be an n -form, since M is oriented). Then for every vector field X on M we have

$$(*) \quad d(X \lrcorner dV) = (\operatorname{div} X) \cdot dV.$$

PROOF. If $(*)$ holds for X_1 and X_2 , then it clearly holds for $X_1 + X_2$. Moreover, if $(*)$ holds for X , then

$$\begin{aligned} d(fX \lrcorner dV) &= d(f \cdot (X \lrcorner dV)) \\ &= df \wedge (X \lrcorner dV) + f \cdot d(X \lrcorner dV) \\ &= df \wedge (X \lrcorner dV) + f \cdot \operatorname{div} X \cdot dV. \end{aligned}$$

Now Problem I.7-4(f) gives

$$\begin{aligned} 0 &= X \lrcorner (df \wedge dV) = (X \lrcorner df) \wedge dV - df \wedge (X \lrcorner dV) \\ &= X(f) \cdot dV - df \wedge (X \lrcorner dV), \end{aligned}$$

so our formula becomes

$$\begin{aligned} d(fX \lrcorner dV) &= X(f) \cdot dV + f \cdot \operatorname{div} X \cdot dV \\ &= (\operatorname{div} fX) \cdot dV \quad \text{by (2).} \end{aligned}$$

Thus $(*)$ is also true for fX .

Now let X_1, \dots, X_n be a positively oriented orthonormal moving frame, with dual forms $\theta^1, \dots, \theta^n$, so that $dV = \theta^1 \wedge \dots \wedge \theta^n$. By the considerations of the previous paragraph, it suffices to prove $(*)$ when X is some X_i , and we might as well take $X = X_1$. We easily see that

$$X_1 \lrcorner dV = X_1 \lrcorner (\theta^1 \wedge \dots \wedge \theta^n) = \theta^2 \wedge \dots \wedge \theta^n.$$

So

$$\begin{aligned} d(X_1 \lrcorner dV) &= d(\theta^2 \wedge \dots \wedge \theta^n) = \sum_{j=2}^n (-1)^j \theta^2 \wedge \dots \wedge d\theta^j \wedge \dots \wedge \theta^n \\ &= - \sum_{j=2}^n (-1)^j \theta^2 \wedge \dots \wedge \left(\sum_{i=1}^n \omega_i^j \wedge \theta^i \right) \wedge \dots \wedge \theta^n \\ &= - \sum_{j=2}^n (-1)^j \theta^2 \wedge \dots \wedge (\omega_1^j \wedge \theta^1) \wedge \dots \wedge \theta^n \\ &= - \sum_{j=2}^n (-1)^j \omega_1^j \wedge \theta^1 \wedge \dots \wedge \widehat{\theta^j} \wedge \dots \wedge \theta^n. \end{aligned}$$

But

$$\omega_1^j = \sum_{k=1}^n \omega_1^j(X_k) \cdot \theta^k = \sum_{k=1}^n \langle \nabla_{X_k} X_1, X_j \rangle \theta^k,$$

so we obtain

$$\begin{aligned} d(X_1 \lrcorner dV) &= \sum_{j=2}^n \langle \nabla_{X_j} X_1, X_j \rangle \theta^1 \wedge \cdots \wedge \theta^n \\ &= (\operatorname{div} X_1) dV. \quad \spadesuit \end{aligned}$$

As an easy corollary we now obtain

57. THEOREM (THE DIVERGENCE THEOREM). Let M be a compact oriented n -dimensional Riemannian manifold-with-boundary, with outward pointing unit normal v on ∂M . Denote the volume element of M by dV_n , and that of ∂M by dV_{n-1} . Let X be a vector field on M . Then

$$\int_M \operatorname{div} X \, dV_n = \int_{\partial M} \langle X, v \rangle \, dV_{n-1}.$$

PROOF. This follows from Stokes' Theorem, and the easily verified fact that $X \lrcorner dV_n$ equals $\langle X, v \rangle dV_{n-1}$ on ∂M . \spadesuit

58. COROLLARY (GREEN'S THEOREM). If M is a compact oriented n -dimensional Riemannian manifold without boundary, and X is any vector field on M , then

$$\int_M \operatorname{div} X \, dV_n = 0.$$

Notice that even when M is not orientable, equation (*) in Lemma 56 can be used to define $\operatorname{div} X$, for both sides of the equation change sign when the orientation is reversed, so locally the formula defines $\operatorname{div} X$ unambiguously.

We now define the Laplacian Δf of f on M by

$$(IV) \quad \Delta f = \operatorname{div}(\operatorname{grad} f).$$

For a coordinate system x^1, \dots, x^n on M we have, with the notation of Chapter II.5,

$$\begin{aligned}\Delta f &= \sum_{i=1}^n \left(\sum_{j=1}^n g^{ij} \frac{\partial f}{\partial x^j} \right)_{;i} = \sum_{i=1}^n \left(\sum_{j=1}^n g^{ij} f_{;j} \right)_{;i} \\ &= \sum_{i,j=1}^n g^{ij} f_{;ji} = \sum_{i,j=1}^n g^{ij} f_{;ij} \\ &= \sum_{i,j=1}^n g^{ij} \left(\frac{\partial^2 f}{\partial x^i \partial x^j} - \sum_{k=1}^n \frac{\partial f}{\partial x^k} \Gamma_{ij}^k \right).\end{aligned}$$

If x^1, \dots, x^n is a normal coordinate system at p , so that $\Gamma_{ij}^k(p) = 0$, and $g_{ij}(p) = \delta_{ij}$, then

$$\Delta f(p) = \sum_{i=1}^n \frac{\partial^2 f}{\partial (x^i)^2}(p).$$

We can also state a more precise result along these lines. Suppose that X_1, \dots, X_n are vector fields which are orthonormal at p . Then

$$\begin{aligned}(\text{IV}') \quad \Delta f(p) &= \text{div}(\text{grad } f)(p) \\ &= \text{trace } X \mapsto \nabla_X \text{grad } f \quad X \in M_p \\ &= \sum_{i=1}^n \langle \nabla_{X_i(p)} \text{grad } f, X_i(p) \rangle \\ &= \sum_{i=1}^n X_i(p) \langle \text{grad } f, X_i \rangle - \sum_{i=1}^n \langle (\text{grad } f)(p), \nabla_{X_i(p)} X_i \rangle \\ &= \sum_{i=1}^n X_i(p) (df(X_i)) - \sum_{i=1}^n \langle (\text{grad } f)(p), \nabla_{X_i(p)} X_i \rangle \\ &= \sum_{i=1}^n (X_i X_i f)(p) - \sum_{i=1}^n \langle (\text{grad } f)(p), \nabla_{X_i(p)} X_i \rangle.\end{aligned}$$

So we have

$$(\text{IV}'') \quad \Delta f(p) = \sum_{i=1}^n (X_i X_i f)(p) \quad \text{for} \quad \begin{cases} X_1, \dots, X_n \text{ orthonormal at } p \\ \nabla_{X_i} X_i = 0 \text{ at } p. \end{cases}$$

We ought to mention that the Laplacian Δf on a surface was first introduced by Beltrami, so Δ is often called the Laplace-Beltrami operator. For reasons that

will appear in the next Addendum, the Laplacian is often defined as the negative of the Laplacian as defined here. There is no general agreement on the proper sign, so whenever a lecturer states that her Laplacian is the usual one (or the negative of the usual one), one half of the audience (or the other half) raises their eyebrows and murmurs disgruntledly “hmmph, so she calls *that* the usual Laplacian!”

A simple calculation [using normal coordinates, or equation (IV''), to make things even easier] shows that

$$(4) \quad \Delta(fg) = f \cdot \Delta g + g \cdot \Delta f + 2\langle \text{grad } f, \text{grad } g \rangle.$$

We will use this formula to derive a result of importance later on.

59. PROPOSITION. Let M be a compact oriented n -dimensional Riemannian manifold-with-boundary, with outward pointing unit normal v on ∂M . Then

$$\int_M [f \Delta f + \langle \text{grad } f, \text{grad } f \rangle] dV_n = \int_{\partial M} \langle f \text{grad } f, v \rangle dV_{n-1}.$$

In particular, if $f = 0$ on ∂M [and, *a posteriori* if $\partial M = \emptyset$], then

$$\int_M f \Delta f dV_n = - \int_M \langle \text{grad } f, \text{grad } f \rangle dV_n.$$

PROOF. The Divergence Theorem (Theorem 57) gives

$$\int_M \Delta(f^2) dV_n = \int_M \text{div}(\text{grad } f^2) dV_n = \int_{\partial M} \langle \text{grad } f^2, v \rangle dV_{n-1}.$$

Then equations (1) and (4) give the result. ♦

As a corollary we have

60. LEMMA (BOCHNER'S LEMMA). Let M be a compact connected Riemannian manifold (without boundary). If $f: M \rightarrow \mathbb{R}$ has $\Delta f \geq 0$ everywhere, then f is a constant function (and $\Delta f = 0$).

PROOF. We can assume that M is orientable, by taking the orientable 2-fold covering space of M if necessary. First of all, Corollary 58 gives

$$\int_M \Delta f dV = \int_M \text{div}(\text{grad } f) dV = 0.$$

Since $\Delta f \geq 0$ on M , this already implies that $\Delta f = 0$ on M . Now (the second part of) Proposition 59 gives

$$0 = \int_M f \Delta f \, dV = - \int_M \langle \text{grad } f, \text{grad } f \rangle \, dV.$$

So we must have $\text{grad } f = 0 \implies df = 0 \implies f$ is constant. \blacklozenge

An alternative proof of Lemma 60 is given in Addendum 2 to Chapter 10.

A couple of explicit calculations of the Laplacian will be used at various times. Our first calculation is most easily carried out in a coordinate system. Consider a 1-form

$$\omega = \sum_i a_i \, dx^i,$$

and the vector field

$$X = \sum_i a^i \frac{\partial}{\partial x^i}, \quad a^i = \sum_j g^{ij} a_j.$$

This vector field X is described intrinsically by the equation

$$\langle X, Y \rangle = \omega(Y) \quad \text{for all vector fields } Y,$$

so that, in particular,

$$\langle X, X \rangle = \omega(X) = \sum_i a^i a_i.$$

Now

$$\begin{aligned} \Delta \left(\sum_i a^i a_i \right) &= \sum_{j,k} g^{jk} \left(\sum_i a^i a_i \right)_{;jk} \\ &= \sum_{j,k} g^{jk} \sum_i (a^i_{;j} a_i + a^i a_{i;j})_{;k} \\ &= \sum_{j,k} g^{jk} \sum_i (a^i_{;jk} a_i + a^i_{;j} a_{i;k} + a^i_{;k} a_{i;j} + a^i a_{i;jk}). \end{aligned}$$

Since

$$\begin{aligned} \sum_{i,j,k} g^{jk} a^i_{;jk} a_i &= \sum_{i,j,k} \sum_{l,m} g^{jk} g^{il} a_{l;jk} g_{im} a^m \\ &= \sum_{j,k,m} g^{jk} a_{m;jk} a^m = \sum_{i,j,k} g^{jk} a_{i;jk} a^i, \end{aligned}$$

and

$$\sum_{i,j,k} g^{jk} a^i_{,j} a_{i;k} = \sum_{i,j,k} \sum_l g^{jk} g^{il} a_{l;j} a_{i;k},$$

we have, finally,

$$(5) \quad \Delta \left(\sum_i a^i a_i \right) = 2 \left(\sum_{i,j,k} g^{jk} a^i a_{i;jk} + \sum_{i,j,k,l} g^{jk} g^{il} a_{i;k} a_{l;j} \right).$$

Our second calculation is easily carried out in a coordinate-free way. Consider an immersion $f: M^n \rightarrow \mathbb{R}^m$, so that M has a Riemannian metric $I_f = f^*\langle \cdot, \cdot \rangle$. We will compute Δf with respect to this metric (the fact that f is \mathbb{R}^m -valued causes no difficulty, for we can compute the Laplacian of each of its component functions—for simplicity we suppress the various components and simply use formula (IV'') for \mathbb{R}^m -valued f). It will make things conceptually easier to think of M^n as a subset of \mathbb{R}^m , so that f is the inclusion map. Let X_1, \dots, X_n be vector fields on M satisfying the conditions of (IV''). We first want to figure out what the \mathbb{R}^m -valued function $X_i(f)$ is. Now

$$\begin{aligned} X_i(f) &= df(X_i) = \text{“the vector part of” } f_*(X_i) && \text{by Problem I.4-3} \\ &= X_i && \text{(when } X_i \text{ is considered as a point of } \mathbb{R}^m\text{).} \end{aligned}$$

Therefore,

$$\begin{aligned} X_i(X_i f)(p) &= \nabla'_{X_i} X_i(p) \\ &= \nabla_{X_i} X_i(p) + s(X_i(p), X_i(p)) \\ &= s(X_i(p), X_i(p)) && \text{by our conditions on } X_1, \dots, X_n. \end{aligned}$$

Thus we see that

$$(6) \quad \Delta f(p) = n \cdot \eta(p),$$

where η is the mean curvature normal. Notice, in particular, that if M has $\eta = 0$, then $\Delta f = 0$. Lemma 60 then implies that M cannot be compact (for $n \geq 1$), which reproves Corollary 31. In the particular case of a hypersurface, we have

$$(7) \quad \Delta f = nH \cdot \nu,$$

where ν is the unit normal field.

Notice the correspondence between equation (7) and equation (II') on pg. III.109, which can be written in the simple form

$$\Delta_{\langle \cdot, \cdot \rangle} f = \mathcal{N},$$

where $\Delta_{\langle \cdot, \cdot \rangle}$ indicates the Laplacian with respect to the metric $\langle \cdot, \cdot \rangle$ on M . Since the Laplacian is such a natural operator on a Riemannian manifold, it is not surprising to find $\Delta_{\langle \cdot, \cdot \rangle} f$ related to \mathcal{N} . (Note also that $\Delta_{\langle \cdot, \cdot \rangle}$ involves g_{ij} and Christoffel symbols Γ_{ij}^k , and thus third derivatives of f , just like \mathcal{N}). As a matter of fact, this equation was originally used as the *definition* of \mathcal{N} (it is clearly a special linear affine invariant!).

The Laplacian can be generalized in two very important ways. One such generalization is treated in the next Addendum. A different generalization, important in Chapter 9, is suggested by the next to last line of equation (IV'), which can be written

$$\Delta f(p) = \sum_{i=1}^n X_i(p)(df(X_i)) - \sum_{i=1}^n df(\nabla_{X_i(p)} X_i)$$

X_1, \dots, X_n orthonormal at p .

Now Corollary II.6-5 says that the covariant derivative ∇df is given by

$$(\nabla_{X_p} df)(Y_p) = X_p(df(Y)) - df(\nabla_{X_p} Y)$$

for any vector fields X, Y extending X_p, Y_p . Thus we can write

$$\Delta f(p) = \sum_{i=1}^n (\nabla_{X_i} df)(X_i) \quad X_1, \dots, X_n \in M_p \text{ orthonormal.}$$

Thus, using (III) we can just as well define Δf by

$$\Delta f = \operatorname{div}(df).$$

[Naturally, one could, with some work, demonstrate the equation $\operatorname{div}(\operatorname{grad} f) = \operatorname{div}(df)$ directly from the completely invariant definitions.]

The nice thing about this new definition of Δf is that it can be generalized immediately. Consider a vector bundle $\varpi: E \rightarrow M$, where M has a metric $\langle \cdot, \cdot \rangle$, and E has some connection D . If ξ is any section of E , then $D_{X_p} \xi \in \varpi^{-1}(p)$ for $X_p \in M_p$. We can therefore think of $D\xi$ as a section of the bundle $\operatorname{Hom}(TM, E)$ whose fibre at p is $\operatorname{Hom}(M_p, \varpi^{-1}(p))$. Now the connection ∇ on M determined by $\langle \cdot, \cdot \rangle$, together with the connection D on E , determines

a connection $\tilde{\nabla}$ on $\text{Hom}(TM, E)$. This is defined as on page 37, except that the situation is even simpler. As in that case, we easily see that for any vector fields X, Y and any section ψ on $\text{Hom}(TM, E)$, we have

$$(8) \quad (\tilde{\nabla}_{X_p} \psi)(Y_p) = D_{X_p}(\psi(Y)) - \psi(\nabla_{X_p} Y).$$

[If $E = M \times \mathbb{R}$, so that the sections of E are functions $f: M \rightarrow \mathbb{R}$, and we define $D_X f$ to be $df(X)$, then $\tilde{\nabla}$ will just be the connection ∇ on 1-forms.] Naturally $\tilde{\nabla}\psi$ will denote the section of $\text{Hom}(TM \times TM, E)$ with

$$(\tilde{\nabla}\psi)(X, Y) = (\tilde{\nabla}_X \psi)(Y).$$

For a section ξ of E we can now define

$$(V) \quad \Delta\xi(p) = \sum_{i=1}^n (\tilde{\nabla}_{X_i} D\xi)(X_i) \quad X_1, \dots, X_n \in M_p \text{ orthonormal.}$$

(A completely invariant definition is easily formulated, as before.) If we let X_1, \dots, X_n be vector fields which are orthonormal at p , then

$$\begin{aligned} (V') \quad \Delta\xi(p) &= \sum_{i=1}^n (\tilde{\nabla}_{X_i(p)} D\xi)(X_i(p)) \\ &= \sum_{i=1}^n D_{X_i(p)}(D\xi(X_i)) - \sum_{i=1}^n D\xi(\nabla_{X_i(p)} X_i) \quad \text{by (8)} \\ &= \sum_{i=1}^n D_{X_i(p)} D_{X_i} \xi - \sum_{i=1}^n D\xi(\nabla_{X_i(p)} X_i). \end{aligned}$$

So we have, in complete analogy with equation (IV''),

$$(V'') \quad \Delta\xi(p) = \sum_{i=1}^n (D_{X_i} D_{X_i} \xi)(p) \quad \text{for} \quad \begin{cases} X_1, \dots, X_n \text{ orthonormal at } p \\ \nabla_{X_i} X_i = 0 \text{ at } p. \end{cases}$$

ADDENDUM 2

THE $*$ OPERATOR AND THE
LAPLACIAN ON FORMS; HODGE'S THEOREM

Let V be an oriented n -dimensional vector space with an inner product $\langle \cdot, \cdot \rangle$. The $*$ operator, from alternating k -linear functions $\Omega^k(V)$ to $\Omega^{n-k}(V)$, is usually defined as follows. Let v_1, \dots, v_n be a positively oriented orthonormal basis of V , and let ϕ_1, \dots, ϕ_n be the dual basis. Then

$$*(\phi_{i_1} \wedge \cdots \wedge \phi_{i_k}) = \pm \phi_{j_1} \wedge \cdots \wedge \phi_{j_{n-k}},$$

where i_1, \dots, i_k are k distinct numbers from $1, \dots, n$, and j_1, \dots, j_{n-k} are the other $n - k$ numbers of this set, arranged in some order; we use the $+$ sign if $v_{i_1}, \dots, v_{i_k}, v_{j_1}, \dots, v_{j_{n-k}}$ is positively oriented, and the $-$ sign otherwise. We also set $*1 = \pm \phi_1 \wedge \cdots \wedge \phi_n$, where $1 \in \Omega^0(V) = \mathbb{R}$, and $*(\phi_1 \wedge \cdots \wedge \phi_n) = \pm 1$. It is easy to see, first of all, that this definition is consistent, for a fixed basis v_1, \dots, v_n , and then that the definition is also independent of the orthonormal basis. An invariant definition can be given as follows. We always have a map

$$\Omega^k(V) \times \Omega^{n-k}(V) \xrightarrow{\wedge} \Omega^n(V).$$

An orientation and inner product on V gives us an isomorphism $\Omega^n(V) \xrightarrow{\approx} \mathbb{R}$, so we have a bilinear map

$$\{ \cdot, \cdot \}: \Omega^k(V) \times \Omega^{n-k}(V) \rightarrow \mathbb{R}.$$

Then we can define

$$A: \Omega^k(V) \rightarrow (\Omega^{n-k}(V))^*$$

by

$$A(\omega)(\eta) = \{\omega, \eta\} \quad \omega \in \Omega^k(V), \quad \eta \in \Omega^{n-k}(V).$$

Now the inner product on V also gives us an isomorphism $V \rightarrow V^*$ from which we derive an isomorphism $(\Omega^{n-k}(V))^* \rightarrow \Omega^{n-k}(V)$. One easily checks that the composition

$$\Omega^k(V) \xrightarrow{A} (\Omega^{n-k}(V))^* \rightarrow \Omega^{n-k}(V)$$

is precisely $*$. Straightforward calculations show that

$$(1) \quad ** = * \circ *: \Omega^k(V) \rightarrow \Omega^k(V) \quad \text{is } (-1)^{k(n-k)} \text{ times the identity.}$$

In Chapter I.9 we mentioned that the inner product on V gives inner products on all vector spaces $\Omega^k(V)$, although we did not describe most of these inner products explicitly. The inner product on $\Omega^1(V) = V^*$ can be described by the condition that the dual basis ϕ^1, \dots, ϕ^n is orthonormal if and only if v_1, \dots, v_n is orthonormal in V . Using the inner product $\langle \cdot, \cdot \rangle$ thus defined on $\Omega^1(V)$, we can describe the inner product on $\Omega^k(V)$ as the unique one with

$$(2) \quad \langle \phi_1 \wedge \dots \wedge \phi_k, \psi_1 \wedge \dots \wedge \psi_k \rangle = \det(\langle \phi_i, \psi_j \rangle)$$

for $\phi_i, \psi_j \in V^*$. In particular, if ϕ_1, \dots, ϕ_n is orthonormal in V^* , then

$$\begin{aligned} & \langle \phi_{i_1} \wedge \dots \wedge \phi_{i_k}, \phi_1 \wedge \dots \wedge \phi_k \rangle \\ &= \det \begin{pmatrix} \delta_{i_1 1} & \dots & \delta_{i_1 k} \\ \vdots & & \vdots \\ \delta_{i_k 1} & \dots & \delta_{i_k k} \end{pmatrix} \\ &= \begin{cases} 0 & \text{if } \{i_1, \dots, i_k\} \neq \{1, \dots, k\} \\ \text{sgn } \pi & \text{if } i_\alpha = \pi(\alpha) \text{ for some permutation } \pi \text{ of } \{1, \dots, k\}. \end{cases} \end{aligned}$$

Since the naming of the indices was purely arbitrary, we have, just as well,

$$(3) \quad \langle \phi_{i_1} \wedge \dots \wedge \phi_{i_k}, \phi_{j_1} \wedge \dots \wedge \phi_{j_k} \rangle = \begin{cases} 0 & \text{if } \{i_1, \dots, i_k\} \neq \{j_1, \dots, j_k\} \\ \text{sgn } \pi & \text{if } j_\alpha = \pi(i_\alpha). \end{cases}$$

So we can also describe the inner product on $\Omega^k(V)$ as the one which makes the $\phi_{i_1} \wedge \dots \wedge \phi_{i_k}$ ($i_1 < \dots < i_k$) an orthonormal basis, for any orthonormal basis ϕ_1, \dots, ϕ_n of V^* .

Now note that

$$\begin{aligned} \phi_{i_1} \wedge \dots \wedge \phi_{i_k} \wedge *(\phi_1 \wedge \dots \wedge \phi_k) &= \phi_{i_1} \wedge \dots \wedge \phi_{i_k} \wedge \pm \phi_{k+1} \wedge \dots \wedge \phi_n \\ &= \begin{cases} 0 & \text{if } \{i_1, \dots, i_k\} \neq \{1, \dots, k\} \\ (\text{sgn } \pi) \cdot *1 & \text{if } i_\alpha = \pi(\alpha). \end{cases} \end{aligned}$$

Again, since the naming of the indices was arbitrary, we have, just as well,

$$(4) \quad \phi_{i_1} \wedge \dots \wedge \phi_{i_k} \wedge *(\phi_{j_1} \wedge \dots \wedge \phi_{j_k}) = \begin{cases} 0 & \text{if } \{i_1, \dots, i_k\} \neq \{j_1, \dots, j_k\} \\ (\text{sgn } \pi) \cdot *1 & \text{if } j_\alpha = \pi(i_\alpha). \end{cases}$$

Comparing (3) and (4), we see that for $\omega, \eta \in \Omega^k(V)$ we have

$$(5) \quad \langle \omega, \eta \rangle = *(\omega \wedge *\eta) = *(\eta \wedge *\omega).$$

Now everything that we have done can be extended to k -forms on an oriented Riemannian n -manifold $(M, \langle \cdot, \cdot \rangle)$. We have an operator $*$ taking k -forms to $(n - k)$ -forms, and $** = (-1)^{k(n-k)}$ on k -forms. It is easy to check (using the dual forms to an orthonormal moving frame, for example) that $*$ takes C^∞ forms to C^∞ forms. Note that the volume element dV on M is just $*1$ for the constant function (0-form) 1.

We also have, for two k -forms, ω and η , a function $\langle \omega, \eta \rangle$ on M . We would like a formula for $\langle \omega, \eta \rangle$ when we have coordinate expressions

$$(a) \quad \omega = \sum_{i_1 < \dots < i_k} a_{i_1 \dots i_k} dx^{i_1} \wedge \dots \wedge dx^{i_k}$$

$$(b) \quad \eta = \sum_{j_1 < \dots < j_k} b_{j_1 \dots j_k} dx^{j_1} \wedge \dots \wedge dx^{j_k}.$$

For this, and later, purposes, it will be convenient to express a form in terms of tensor products of the dx^i , instead of wedge products. Recall (Theorem I.7-2(3)) that

$$\begin{aligned} dx^{i_1} \wedge \dots \wedge dx^{i_k} &= \frac{(1 + \dots + 1)!}{1! \dots 1!} \text{Alt}(dx^{i_1} \otimes \dots \otimes dx^{i_k}) \\ &= \sum_{\sigma \in S_k} \text{sgn } \sigma \, dx^{\sigma(i_1)} \otimes \dots \otimes dx^{\sigma(i_k)}. \end{aligned}$$

This shows that the expression (a) can also be written

$$\omega = \sum_{i_1, \dots, i_k} a_{i_1 \dots i_k} dx^{i_1} \otimes \dots \otimes dx^{i_k},$$

where the new $a_{i_1 \dots i_k}$ are skew-symmetric in the indices i_1, \dots, i_k and agree with the old $a_{i_1 \dots i_k}$ when $i_1 < \dots < i_k$. Now let g_{ij} be the components of $\langle \cdot, \cdot \rangle$ in our coordinate system, so that g^{ij} are the components of $\langle \cdot, \cdot \rangle$ on the dual space. With any tensor, covariant of order k ,

$$A = \sum_{i_1, \dots, i_k} a_{i_1 \dots i_k} dx^{i_1} \otimes \dots \otimes dx^{i_k},$$

we can associate the tensor, contravariant of order k ,

$$\tilde{A} = \sum_{j_1, \dots, j_k} a^{j_1 \dots j_k} \frac{\partial}{\partial x^{j_1}} \otimes \dots \otimes \frac{\partial}{\partial x^{j_k}},$$

where

$$(6) \quad a^{j_1 \dots j_k} = \sum_{i_1, \dots, i_k} g^{i_1 j_1} \dots g^{i_k j_k} a_{i_1 \dots i_k}.$$

In the special case where

$$A = \sum_i a_i dx^i,$$

it is clear how \tilde{A} is described invariantly: if we think of $\tilde{A}(p)$ as a linear function on M_p^* , then

$$\tilde{A}(p)(\phi) = A(p)(S(\phi)),$$

where $S: M_p^* \rightarrow M_p$ is the isomorphism given by the metric. In general,

$$\tilde{A}(p)(\phi_1, \dots, \phi_k) = A(p)(S(\phi_1), \dots, S(\phi_k)).$$

Notice that if the $a_{i_1 \dots i_k}$ are skew-symmetric in the indices, then so are the $a^{j_1 \dots j_k}$. So if ω is given by (a), then $\tilde{\omega}$ is also given by

$$\tilde{\omega} = \sum_{j_1 < \dots < j_k} a^{j_1 \dots j_k} \frac{\partial}{\partial x^{j_1}} \wedge \dots \wedge \frac{\partial}{\partial x^{j_k}}$$

[note, however, that the $a^{j_1 \dots j_k}$ are computed from (6), in which $a_{i_1 \dots i_k}$ is defined, by skew-symmetry, for all i_1, \dots, i_k]. We now claim that for ω, η given by (a) and (b), we have

$$(7) \quad \begin{aligned} \langle \omega, \eta \rangle &= \sum_{i_1 < \dots < i_k} a_{i_1 \dots i_k} b^{i_1 \dots i_k} = \sum_{i_1 < \dots < i_k} a^{i_1 \dots i_k} b_{i_1 \dots i_k} \\ &= \frac{1}{k!} \sum_{i_1, \dots, i_k} a_{i_1 \dots i_k} b^{i_1 \dots i_k} = \frac{1}{k!} \sum_{i_1, \dots, i_k} a^{i_1 \dots i_k} b_{i_1 \dots i_k}. \end{aligned}$$

To prove this, we note that the last two expressions can be defined invariantly as contractions (traces) of $\omega \otimes \tilde{\eta}$ or $\tilde{\omega} \otimes \eta$. So it suffices to check that (7) holds at a point p where dx^1, \dots, dx^n are orthonormal. In this case $g^{ij} = \delta^{ij}$ at p , so $a^{i_1 \dots i_k} = a_{i_1 \dots i_k}$ at p . The desired result then follows immediately from equation (3).

On the oriented Riemannian n -manifold M we can also do something else. Since we have the map d , which raises the degree of a form, we can define a map δ , which lowers the degree of a form, by

$$\delta = (-1)^{n(k+1)+1} * d * \quad \text{from } k\text{-forms to } (k-1)\text{-forms.}$$

We clearly have $\delta^2 = 0$, and $\delta = 0$ on functions (0-forms). Note that on k -forms we have

$$\begin{aligned}
 (8) \quad * \delta &= (-1)^{n(k+1)+1} (**) d* \\
 &= (-1)^{n(k+1)+1} \cdot (-1)^{(n-k+1)(k-1)} d* \\
 &\quad \text{by (1) [since } d* \text{ of a } k\text{-form is an } n-k+1 \text{ form]} \\
 &= (-1)^k d*,
 \end{aligned}$$

and similarly

$$(9) \quad \delta* = (-1)^{k+1} *d.$$

Notice that δ can really be defined even when M is not orientable, for its definition is local, and changing the orientation of M reverses the sign of $*$, so leaves δ unchanged. We now define an operator Δ from k -forms to k -forms by

$$\Delta = \delta d + d\delta.$$

The reader may check that on 0-forms this Δ is the negative of the one in the previous Addendum. [N. B. The connection ∇ on M gives rise in a natural way to a connection ∇ on the bundle of k -forms on M , so the final definition of the previous Addendum also gives us a Laplacian on k -forms. But that Laplacian is *not* related to the one defined here.] Simple computations, using (8) and (9) for the last equation, give

$$(10) \quad d\Delta = \Delta d, \quad \delta\Delta = \Delta\delta, \quad *\Delta = \Delta*.$$

On a compact oriented manifold M we can define the inner product (ω, η) of two k -forms ω, η by

$$(\omega, \eta) = \int_M \langle \omega, \eta \rangle dV = \int_M \omega \wedge *\eta \quad \text{by (5).}$$

This inner product $(\ , \)$ is clearly symmetric and positive definite. Now if ω is a $(k-1)$ -form and η is a k -form, then

$$\begin{aligned}
 d(\omega \wedge *\eta) &= d\omega \wedge *\eta + (-1)^{k-1} \omega \wedge d*\eta \\
 &= d\omega \wedge *\eta - \omega \wedge *\delta\eta \quad \text{by (8).}
 \end{aligned}$$

So Stokes' Theorem gives

$$0 = \int_M d(\omega \wedge *\eta) = \int_M d\omega \wedge *\eta - \int_M \omega \wedge *\delta\eta,$$

or

$$(11) \quad (d\omega, \eta) = (\omega, \delta\eta).$$

Thus δ is the “adjoint” of d for the inner product $(\ , \)$, and this property characterizes $\delta\eta$, since $(\ , \)$ is positive definite. From this we easily see that Δ is self-adjoint with respect to the inner product $(\ , \)$ on k -forms,

$$(12) \quad (\Delta\omega, \eta) = (\omega, \Delta\eta).$$

In Euclidean space, a function f with $\Delta f = 0$ is called harmonic. In an oriented Riemannian manifold $(M, \langle \ , \ \rangle)$ we call a k -form ω **harmonic** if $\Delta\omega = 0$. When M is compact, we can write

$$(\Delta\omega, \omega) = ([d\delta + \delta d]\omega, \omega) = (\delta\omega, \delta\omega) + (d\omega, d\omega),$$

which shows that

$$(13) \quad \Delta\omega = 0 \implies d\omega = 0 \text{ and } \delta\omega = 0, \quad M \text{ compact}$$

(the converse is trivial). If ω and η are k -forms, and $\Delta\omega = 0$, then equation (12) gives

$$(\Delta\eta, \omega) = (\eta, \Delta\omega) = 0.$$

So the vector space of all harmonic k -forms (the kernel of Δ) is orthogonal to the image of Δ . The fundamental result on harmonic forms states that these two orthogonal subspaces of the k -forms span the whole vector space of k -forms:

THE HODGE DECOMPOSITION THEOREM. If M is a compact oriented Riemannian n -manifold, then for each k with $0 \leq k \leq n$, the vector space H^k of harmonic k -forms is finite dimensional, and the vector space $E^k(M)$ of all k -forms on M can be written as an orthogonal direct sum decomposition

$$E^k(M) = \Delta(E^k(M)) \oplus H^k(M).$$

For a proof of this result, which is completely analytic in nature, the reader is referred to Warner [1]; the proof given there is elementary and completely self-contained. We will merely indicate the consequences of the theorem for the

de Rham cohomology. The orthogonal decomposition of $E^k(M)$ gives two projection maps

$$\begin{array}{ccc} & & H^k(M) \\ & \nearrow H^k & \\ E^k(M) & & \\ & \searrow h^k & \\ & & \Delta E^k(M). \end{array}$$

For any $\alpha \in E^k(M)$, the form $h^k(\alpha) = \alpha - H^k(\alpha)$ is uniquely $\Delta\omega$ for some ω . Set

$$G(\alpha) = \text{the unique } \omega \text{ with } \Delta\omega = \alpha - H^k(\alpha),$$

so that

$$G = [\Delta|_{\Delta(E^k(M))}]^{-1} \circ h^k.$$

Now consider any linear map $T: E^k(M) \rightarrow E^l(M)$ with $T\Delta = \Delta T$ [e.g., $T = d, \delta, \Delta$]. We easily see that

$$T(H^k) \subset H^l, \quad T(\Delta(E^k(M))) \subset \Delta(E^l(M)).$$

So

$$T \circ h^k = h^l \circ T, \quad T \circ [\Delta|_{\Delta(E^k(M))}] = [\Delta|_{\Delta(E^l(M))}] \circ T.$$

From this we see that $GT = TG$. In particular, G commutes with d .

Now let ω be any k -form. Then we have

$$\begin{aligned} \alpha &= \Delta G\alpha + H^k(\alpha) \\ &= d\delta G\alpha + \delta dG\alpha + H^k(\alpha) \\ &= d\delta G\alpha + \delta Gd\alpha + H^k(\alpha). \end{aligned}$$

So if $d\alpha = 0$, then

$$\alpha = d\delta G\alpha + H^k(\alpha).$$

Thus $H^k(\alpha)$ is a harmonic k -form in the same de Rham cohomology class as α . On the other hand, suppose α_1 and α_2 are two harmonic k -forms in the same de Rham cohomology class, so that

$$\alpha_1 - \alpha_2 = d\beta$$

for some β . Then

$$\begin{aligned}(d\beta, d\beta) &= (d\beta, \alpha_1 - \alpha_2) = (\beta, \delta\alpha_1 - \delta\alpha_2) && \text{by (11)} \\ &= 0 && \text{by (13).}\end{aligned}$$

So $d\beta = 0$, or $\alpha_1 = \alpha_2$. Thus there is a *unique* harmonic form in each de Rham cohomology class. In other words, the k -dimensional de Rham cohomology vector space is isomorphic to the vector space $H^k(M)$ of harmonic k -forms.

We will give a simple application of this result in a moment. First we would like to observe that both d and δ can be defined in terms of the connection ∇ of M . For d this is easy.

61. PROPOSITION. If ω is a k -form on a Riemannian manifold, then

$$d\omega = (-1)^k(k+1) \cdot \text{Alt } \nabla\omega.$$

PROOF. Let x^1, \dots, x^n be a normal coordinate system at p , and let

$$\begin{aligned}\omega &= \sum_{i_1 < \dots < i_k} a_{i_1 \dots i_k} dx^{i_1} \wedge \dots \wedge dx^{i_k} \\ &= \sum_{i_1, \dots, i_k} a_{i_1 \dots i_k} dx^{i_1} \otimes \dots \otimes dx^{i_k}, \quad \text{as on page 141.}\end{aligned}$$

Then (pg. II.231)

$$\nabla\omega = \sum_{i_1, \dots, i_k} \sum_h a_{i_1 \dots i_k; h} dx^{i_1} \otimes \dots \otimes dx^{i_k} \otimes dx^h.$$

So

$$\begin{aligned}(k+1)! \text{Alt } \nabla\omega &= \sum_{i_1, \dots, i_k} \sum_h a_{i_1 \dots i_k; h} (k+1)! \text{Alt}(dx^{i_1} \otimes \dots \otimes dx^{i_k} \otimes dx^h) \\ &= \sum_{i_1, \dots, i_k} \sum_h a_{i_1 \dots i_k; h} dx^{i_1} \wedge \dots \wedge dx^{i_k} \wedge dx^h \\ &= k! \sum_{i_1 < \dots < i_k} \sum_h a_{i_1 \dots i_k; h} dx^{i_1} \wedge \dots \wedge dx^{i_k} \wedge dx^h.\end{aligned}$$

by skew-symmetry of the $a_{i_1 \dots i_k}$. So

$$(*) \quad (-1)^k (k+1) \text{Alt } \nabla \omega = \sum_{i_1 < \dots < i_k} \sum_h a_{i_1 \dots i_k; h} dx^h \wedge dx^{i_1} \wedge \dots \wedge dx^{i_k}.$$

But at p we have (Proposition II.5-1)

$$a_{i_1 \dots i_k; h}(p) = \frac{\partial}{\partial x^h} a_{i_1 \dots i_k}(p).$$

So

$$\begin{aligned} & (-1)^k (k+1) \text{Alt } \nabla \omega(p) \\ &= \sum_{i_1 < \dots < i_k} \sum_h \frac{\partial}{\partial x^h} a_{i_1 \dots i_k}(p) dx^h \wedge dx^{i_1} \wedge \dots \wedge dx^{i_k}(p) \\ &= d\omega(p). \quad \blacklozenge \end{aligned}$$

Naturally, the use of a normal coordinate system at p was merely a simplifying device; in an arbitrary coordinate system we would obtain the same result with a little more calculation—the Christoffel symbols in $(*)$ all cancel out after we write all $dx^h \wedge dx^{i_1} \wedge \dots \wedge dx^{i_k}$ in terms of increasing sequences of indices. The formula

$$d\omega = \sum_{i_1 < \dots < i_k} \sum_h a_{i_1 \dots i_k; h} dx^h \wedge dx^{i_1} \wedge \dots \wedge dx^{i_k},$$

which follows from $(*)$ and the final result of the theorem, can be rewritten as follows:

$$d\omega = \sum_{j_1 < \dots < j_{k+1}} b_{j_1 \dots j_{k+1}} dx^{j_1} \wedge \dots \wedge dx^{j_{k+1}},$$

for

$$b_{j_1 \dots j_{k+1}} = \sum_{\mu=1}^{k+1} (-1)^{\mu+1} a_{j_1 \dots \widehat{j_\mu} \dots j_{k+1}; j_\mu}.$$

Notice that if the a 's are skew-symmetric, then the b 's will be also.

Now suppose that we have a $(k+1)$ -form

$$\eta = \sum_{j_1 < \dots < j_{k+1}} c_{j_1 \dots j_{k+1}} dx^{j_1} \wedge \dots \wedge dx^{j_{k+1}}.$$

Then equation (7) gives

$$\begin{aligned}
 (14) \quad \langle d\omega, \eta \rangle &= \frac{1}{(k+1)!} \sum_{j_1, \dots, j_{k+1}} b_{j_1 \dots j_{k+1}} c^{j_1 \dots j_{k+1}} \\
 &= \frac{1}{(k+1)!} \sum_{j_1, \dots, j_{k+1}} \sum_{\mu=1}^{k+1} (-1)^{\mu+1} a_{j_1 \dots \widehat{j}_\mu \dots j_{k+1}; j_\mu} c^{j_1 \dots j_{k+1}} \\
 &= \frac{1}{(k+1)!} \sum_{j_1, \dots, j_{k+1}} \sum_{\mu=1}^{k+1} (-1)^{\mu+1} \cdot -a_{j_1 \dots \widehat{j}_\mu \dots j_{k+1}} c^{j_1 \dots j_{k+1}; j_\mu} \\
 &\quad + \frac{1}{(k+1)!} \sum_{j_1, \dots, j_{k+1}} \sum_{\mu=1}^{k+1} (-1)^{\mu+1} (a_{j_1 \dots \widehat{j}_\mu \dots j_{k+1}} c^{j_1 \dots j_{k+1}})_{; j_\mu} \\
 &= \Sigma_1 + \Sigma_2, \text{ say.}
 \end{aligned}$$

Now it is easy to see that

$$\begin{aligned}
 &\sum_{j_1, \dots, j_{k+1}} a_{j_1 \dots \widehat{j}_\mu \dots j_{k+1}} c^{j_1 \dots j_{k+1}; j_\mu} \\
 &= \sum_{j_1, \dots, j_{k+1}} a^{j_1 \dots \widehat{j}_\mu \dots j_{k+1}} \sum_{\rho} g^{j_\mu \rho} c_{j_1 \dots j_{k+1}; \rho} \\
 &= \sum_{j_1, \dots, j_{k+1}} (-1)^{\mu-1} a^{j_1 \dots \widehat{j}_\mu \dots j_{k+1}} \sum_{\rho} g^{j_\mu \rho} c_{j_\mu j_1 \dots \widehat{j}_\mu \dots j_{k+1}; \rho}.
 \end{aligned}$$

Hence

$$\begin{aligned}
 \Sigma_1 &= \frac{-1}{(k+1)!} \sum_{j_1, \dots, j_{k+1}} \sum_{\mu=1}^{k+1} a^{j_1 \dots \widehat{j}_\mu \dots j_{k+1}} \sum_{\rho} g^{j_\mu \rho} c_{j_\mu j_1 \dots \widehat{j}_\mu \dots j_{k+1}; \rho} \\
 &= \frac{-1}{(k+1)!} \sum_{j_1, \dots, j_{k+1}} \sum_{\mu=1}^{k+1} a^{j_1 \dots \widehat{j}_\mu \dots j_{k+1}} \gamma_{j_1 \dots \widehat{j}_\mu \dots j_{k+1}}, \text{ say} \\
 &= -\frac{k+1}{(k+1)!} \sum_{l_1, \dots, l_k} a^{l_1 \dots l_k} \gamma_{l_1 \dots l_k} \\
 &= -\frac{1}{k!} \sum_{l_1, \dots, l_k} a^{l_1 \dots l_k} \gamma_{l_1 \dots l_k}.
 \end{aligned}$$

Now the γ 's are simply the components of the tensor $\text{div } \eta$, defined by (III') on page 130. So

$$(15) \quad \Sigma_1 = -\langle \omega, \text{div } \eta \rangle.$$

On the other hand, we obtain $k + 1$ well-defined vector fields X_μ with

$$X_\mu = \sum_{\rho=1}^n \left(\sum_{j_1, \dots, j_{k+1}} a_{j_1 \dots \widehat{j_\mu} \dots j_{k+1}} c^{j_1 \dots j_{\mu-1} \rho j_{\mu+1} \dots j_{k+1}} \right) \frac{\partial}{\partial x^\rho}.$$

Then

$$(16) \quad \Sigma_2 = \operatorname{div} \left(\frac{1}{(k+1)!} \sum_{\mu=1}^{k+1} X_\mu \right) = \operatorname{div} Y, \text{ say.}$$

Combining (14), (15), (16), we have

$$(*) \quad \langle d\omega, \eta \rangle = -\langle \omega, \operatorname{div} \eta \rangle + \operatorname{div} Y.$$

From this we conclude

62. PROPOSITION. If η is a $(k+1)$ -form on an oriented Riemannian manifold M , then

$$\delta\eta = -\operatorname{div} \eta.$$

PROOF. First suppose that M is compact. Equation $(*)$ gives, for any k -form ω ,

$$\begin{aligned} \langle d\omega, \eta \rangle &= \int_M \langle d\omega, \eta \rangle dV = \int_M \langle \omega, -\operatorname{div} \eta \rangle dV + \int_M \operatorname{div} Y dV \\ &= \int_M \langle \omega, -\operatorname{div} \eta \rangle dV + 0 \quad \text{by Corollary 58} \\ &= \langle \omega, -\operatorname{div} \eta \rangle. \end{aligned}$$

Since $\delta\eta$ is the unique form with $\langle d\omega, \eta \rangle = \langle \omega, \delta\eta \rangle$ for all k -forms ω , it follows that $\delta\eta = -\operatorname{div} \eta$.

If M is not compact, we can still conclude, from Theorem 57, that $\langle d\omega, \eta \rangle = \langle \omega, -\operatorname{div} \eta \rangle$ for all k -forms ω with compact support. This is still sufficient to imply that $\delta\eta = -\operatorname{div} \eta$. ♦

Now consider a 1-form $\omega = \sum_i a_i dx^i$. Propositions 61 and 62 say that

$$\begin{aligned} d\omega = 0 &\iff a_{i;j} = a_{j;i} \\ \delta\omega = 0 &\iff 0 = \sum_{i,j} g^{ij} a_{i;j} = \sum_i a^i_{;i}. \end{aligned}$$

Suppose that $d\omega = \delta\omega = 0$, and consider the expression (5) on page 136 for $\Delta(\sum_i a^i a_i)$. For the first term in parentheses we have

$$\begin{aligned}
\sum_{i,j,k} g^{jk} a^i a_{i;jk} &= \sum_{i,j,k} g^{jk} a^i a_{j;ik} && \text{since } d\omega = 0 \\
&= \sum_{i,j,k} g^{jk} a^i \left(a_{j;ki} + \sum_l a_l R^l_{jik} \right) && \text{by Ricci's identity} \\
&= \sum_{i,j,k} a^i (g^{jk} a_{j,k})_{;i} + \sum_{i,j,k,l} g^{jk} a^i a_l R^l_{jik} \\
&= 0 + \sum_{i,j,k,l} g^{jk} a^i a_l R^l_{jik} && \text{since } \delta\omega = 0 \\
&= \sum_{i,j,k,l,\mu} g^{jk} a^i g_{l\mu} a^\mu R^l_{jik} \\
&= \sum_{i,j,k,\mu} a^i a^\mu g^{jk} R_{\mu jik} \\
&= - \sum_{i,j,k,\mu} a^i a^\mu g^{jk} R_{j\mu ik} \\
&= - \sum_{i,k,\mu} a^i a^\mu R^k_{\mu ik} \\
&= - \sum_{i,\mu} \text{Ric}_{\mu i} a^i a^\mu.
\end{aligned}$$

Thus we obtain

$$(*) \quad \Delta\left(\sum_i a^i a_i\right) = 2\left[- \sum_{i,j} \text{Ric}_{ij} a^i a^j + \sum_{i,j,k,l} g^{jk} g^{il} a_{i;k} a_{l;j}\right].$$

63. THEOREM (BOCHNER). Let M be a compact oriented Riemannian manifold with $-\text{Ric}(X, X) > 0$ for all $X \neq 0$. (This holds, in particular, if all sectional curvatures of M are > 0 .) Then the 1-dimensional de Rham cohomology of M is zero.

PROOF. Let ω be any 1-form on M with $\Delta\omega = 0$. Then also $d\omega = \delta\omega = 0$, by (13). Then $(*)$ shows that $\Delta(\sum_i a^i a_i) \geq 0$, since the second sum on the right is clearly ≥ 0 . Recall (page 135) that $\sum_i a^i a_i$ is a well-defined function f on M . So Lemma 60 implies that $\Delta(\sum_i a^i a_i) = 0$. By the hypothesis on Ric ,

this implies that $\omega = 0$. In other words, 0 is the only harmonic 1-form. Since the vector space of all harmonic 1-forms is isomorphic to the 1-dimensional de Rham cohomology of M , the theorem follows. ♦

In the next Chapter we will prove that a compact Riemannian manifold M satisfying $-\text{Ric}(X, X) > 0$ for all $X \neq 0$ actually has a finite fundamental group $\pi_1(M)$. Then the result of Theorem 63 follows by algebraic topology. [First we use the Hurewicz theorem to conclude that the first homology group $H_1(M; \mathbb{Z})$ is finite; then the universal coefficient theorem implies that $H^1(M; \mathbb{R}) = \text{Hom}(H_1(M; \mathbb{Z}), \mathbb{R}) = 0$]. However, Theorem 63 has many generalizations, proved using similar techniques, that have never been strengthened in the same way.

ADDENDUM 3

WHEN ARE TWO
RIEMANNIAN MANIFOLDS ISOMETRIC?

Suppose we are given two Riemannian manifolds M, \bar{M} of the same dimension n . We would like a way of finding out whether they are locally isometric. In other words, we ask if there is a point $p \in M$, a point $\bar{p} \in \bar{M}$, and an isometry $\alpha: U \rightarrow \bar{U}$ of a neighborhood U of p onto a neighborhood \bar{U} of \bar{p} . We have a slightly different problem if we are already given p and \bar{p} , and merely seek U and \bar{U} . Admittedly, both of these problems are a little strange, for we are not very likely to be given two explicit Riemannian metrics just out of the clear blue sky; specific metrics which actually come up in practice are so special, and the requirements of isometry so stringent, that there is usually no difficulty seeing whether they are isometric. As a matter of fact, I know of no instance where the (complicated) general methods which we will develop are actually used. But it is nevertheless quite significant that we can now settle the question of isometry in the category of Riemannian manifolds, for this shows that any intrinsic invariant of a Riemannian manifold can be defined in terms of the various invariants (like the curvature tensor) which we have already discovered.

The theory is rather special, and quite pleasant, in the 2-dimensional case. First some preliminaries. For two functions f, g on a Riemannian manifold $(M, \langle \cdot, \cdot \rangle)$, we introduce the classical notation*

$$\Delta_1(f, g) = \langle \text{grad } f, \text{grad } g \rangle, \quad \Delta_1 f = \Delta_1(f, f).$$

It is clear that if $\alpha: M \rightarrow \bar{M}$ is an isometry, and $f, g: \bar{M} \rightarrow \mathbb{R}$, then

$$(1) \quad \bar{\Delta}_1(f \circ \alpha, g \circ \alpha) = \Delta_1(f, g),$$

where $\bar{\Delta}_1$ is formed with respect to the metric on \bar{M} . For a metric

$$\langle \cdot, \cdot \rangle = E du \otimes du + F[du \otimes dv + dv \otimes du] + G dv \otimes dv$$

on a 2-dimensional manifold, we easily compute that

$$\Delta_1(f, g) = \frac{1}{EG - F^2} \left[E \frac{\partial f}{\partial v} \frac{\partial g}{\partial v} - F \left(\frac{\partial f}{\partial v} \frac{\partial g}{\partial u} + \frac{\partial f}{\partial u} \frac{\partial g}{\partial v} \right) + G \frac{\partial f}{\partial u} \frac{\partial g}{\partial u} \right].$$

* In classical differential geometry books, the Laplacian Δf was denoted by $\Delta_2 f$ (and, worst of all, $\Delta_1 f$ was sometimes written as Δf), but we will stick with Δf for the Laplacian.

In particular, we have

$$\Delta_1 u = \frac{G}{EG - F^2}, \quad \Delta_1(u, v) = \frac{-F}{EG - F^2}, \quad \Delta_1 v = \frac{E}{EG - F^2}.$$

This gives

$$\frac{1}{EG - F^2} = \Delta_1 u \cdot \Delta_1 v - \Delta_1(u, v)^2 = \Theta^2(u, v), \quad \text{say,}$$

and thus

$$(2) \quad E = \frac{\Delta_1 v}{\Theta^2(u, v)}, \quad F = \frac{-\Delta_1(u, v)}{\Theta^2(u, v)}, \quad G = \frac{\Delta_1 u}{\Theta^2(u, v)}.$$

This equation shows that the metric $\langle \cdot, \cdot \rangle$ is determined once we know $\Delta_1(u)$, $\Delta_1(u, v)$, and $\Delta_1(v)$ for any coordinate system (u, v) . We can formalize the contents of this equation as follows.

64. LEMMA. Let $\alpha: M \rightarrow \bar{M}$ be a diffeomorphism of 2-dimensional Riemannian manifolds, and for each coordinate system (\bar{u}, \bar{v}) on \bar{M} , define $(u, v) = (\bar{u}, \bar{v}) \circ \alpha$ on M . If α is an isometry, then

$$(*) \quad \Delta_1 u = (\bar{\Delta}_1 \bar{u}) \circ \alpha, \quad \Delta_1(u, v) = \bar{\Delta}_1(\bar{u}, \bar{v}) \circ \alpha, \quad \Delta_1 v = (\bar{\Delta}_1 \bar{v}) \circ \alpha.$$

Conversely, if these equations hold for some collection of coordinate systems (\bar{u}, \bar{v}) whose domains cover \bar{M} , then α is an isometry.

PROOF. Since $u = \bar{u} \circ \alpha$ and $v = \bar{v} \circ \alpha$, the first part of the theorem follows immediately from equation (1). To prove the converse, let the metrics on M and \bar{M} be

$$\langle \cdot, \cdot \rangle = E du \otimes du + \cdots \quad \text{and} \quad \langle \cdot, \cdot \rangle^- = \bar{E} d\bar{u} \otimes d\bar{u} + \cdots.$$

Since

$$du = d(\bar{u} \circ \alpha) = \alpha^*(d\bar{u}), \quad dv = \alpha^*(d\bar{v}),$$

we have

$$\alpha^*(\bar{E} d\bar{u} \otimes d\bar{u} + \cdots) = (\bar{E} \circ \alpha) du \otimes du + \cdots.$$

But the hypothesis $(*)$, together with equation (2), gives $\bar{E} \circ \alpha = E$, etc. ♦

Now consider two metrics $\langle \cdot, \cdot \rangle$ and $\langle \cdot, \cdot \rangle^-$ on two 2-dimensional Riemannian manifolds M and \bar{M} . We want to know if there is locally an isometry $\alpha: M \rightarrow \bar{M}$. It might happen that the curvature K of $\langle \cdot, \cdot \rangle$ is constant. Then α exists if and only if the curvature \bar{K} of $\langle \cdot, \cdot \rangle^-$ is the same constant; if this is the case, then there is a 2-parameter family of isometries α . Suppose instead that the curvature K of $\langle \cdot, \cdot \rangle$ is not constant. We consider a region where the sets $K = \text{constant}$ give a foliation, and we will try to decide whether the isometry exists

in this region. To be sure, the sets $K = \text{constant}$ might look much worse; for example $K = 0$ might be a single point, or a whole set with interior, etc., etc. But in general, the more complicated the decomposition we obtain, the *easier* it will be to handle the problem, for then the sets $\bar{K} = \text{constant}$ must look just as complicated. At any rate, we will, over and over again, restrict our attention to the “general” case, and not worry about the exceptional situations. When the sets $K = \text{constant}$ give a foliation, then the sets $\bar{K} = \text{constant}$ must also, if the required isometry α is to exist. Moreover, the isometry α must take the set $K = c$ onto the set $\bar{K} = c$. However this still leaves a lot of leeway, and does not yet determine α . We now consider the function $\Delta_1 K$. This function might not give us any new information at all, for $\Delta_1 K$ might be a constant on each of the sets $K = \text{constant}$. We will first consider the case where $\Delta_1 K$ is not constant on these sets. In fact, we want to assume that $\Delta_1 K$ varies monotonically on each set $K = \text{constant}$. Then it will “generally” be the case that $(K, \Delta_1 K): M \rightarrow \mathbb{R}^2$ is a local coordinate system for M . This is the situation which we will actually consider. If the isometry α is to exist, then $(\bar{K}, \bar{\Delta}_1 \bar{K}): \bar{M} \rightarrow \mathbb{R}^2$ must also be a local coordinate system for \bar{M} . Suppose this also occurs. Then clearly the isometry α must, in fact, be the composition

$$\alpha = (\bar{K}, \bar{\Delta}_1 \bar{K})^{-1} \circ (K, \Delta_1 K).$$

defined in some open set $U \subset M$. Now the question arises: how do we know whether this α is actually an isometry? There is an easy answer to this question:

Lemma 64 tells us that α is an isometry if and only if

$$\begin{aligned}\Delta_1 K &= \bar{\Delta}_1 \bar{K} \circ \alpha \\ \Delta_1(K, \Delta_1 K) &= \bar{\Delta}_1(\bar{K}, \bar{\Delta}_1 \bar{K}) \circ \alpha \\ \Delta_1(\Delta_1 K) &= \bar{\Delta}_1(\bar{\Delta}_1 \bar{K}) \circ \alpha.\end{aligned}$$

Moreover, the first of these equations is automatic, by the definition of α .

Now consider the opposite extreme, where $\Delta_1 K$ is a function of K . If α exists, then $\bar{\Delta}_1 \bar{K}$ must be the same function of \bar{K} ,

$$(a) \quad \Delta_1 K = f \circ K, \quad \bar{\Delta}_1 \bar{K} = f \circ \bar{K}.$$

We look at the Laplacians ΔK and $\bar{\Delta} \bar{K}$. If $(K, \Delta K)$ is a local coordinate system, then $(\bar{K}, \bar{\Delta} \bar{K})$ must be also, and α must be

$$\alpha = (\bar{K}, \bar{\Delta} \bar{K})^{-1} \circ (K, \Delta K).$$

This α is an isometry if and only if

$$\Delta_1(K, \Delta K) = \bar{\Delta}_1(\bar{K}, \bar{\Delta} \bar{K}) \circ \alpha, \quad \Delta_1(\Delta K) = \bar{\Delta}_1(\bar{\Delta} \bar{K}) \circ \alpha;$$

the extra condition $\Delta_1 K = \bar{\Delta}_1 \bar{K} \circ \alpha$ follows from (a) and the definition of α . This still leaves us with the case where ΔK also fails to be independent of K in the worst possible way, so that in addition to (a) we have

$$(b) \quad \Delta K = g \circ K, \quad \bar{\Delta} \bar{K} = g \circ \bar{K}.$$

Then it turns out (Problem 24) that the surfaces are isometric, and there is a 1-parameter family of isometries between them.

For higher dimensional manifolds the treatment will be more systematic, but correspondingly less concrete. We already know (Corollary II.7-13) that the metric in a normal coordinate system determined by an orthonormal frame X_{1p}, \dots, X_{np} is completely determined by knowing $\langle R(X_i, X_j)X_k, X_l \rangle$, where X_1, \dots, X_n is the moving frame adapted to X_{1p}, \dots, X_{np} . This result gives us a criterion for determining when a neighborhood of $p \in M$ is isometric to a neighborhood of $\bar{p} \in \bar{M}$, but it cannot be regarded as a reasonable solution of our problem, for we may not be able to compute the geodesics, or the parallel translations along these geodesics. All we can compute is the *equations* for the geodesics and for parallel translations—usually we will not be able to solve these equations explicitly. What we want is a criterion involving only quantities directly computable in a coordinate system—like curvature, covariant derivatives of tensors which have already been computed, etc.

Recall the map $\Phi: \mathbb{R} \times M_p \rightarrow M$ (pg. II.270) defined by

$$\Phi(t, X_p) = \exp(tX_p).$$

From the discussion on pp. II.270–278 [c.f. especially Corollary 9 and Theorem 12] we see that the metric in the normal coordinate system determined by X_{1p}, \dots, X_{np} is completely determined once the functions $\mathbf{R}^i_{jkl} \circ \Phi$ are known. Now suppose that the metric is *analytic*. Then its form in normal coordinates is known once we know

$$\frac{\partial(\mathbf{R}^i_{jkl} \circ \Phi)}{\partial t}(0, X_p), \quad \frac{\partial^2(\mathbf{R}^i_{jkl} \circ \Phi)}{\partial t^2}(0, X_p), \quad \dots \quad \text{all } X_p \in M_p.$$

Now

$$(1) \quad \frac{\partial(\mathbf{R}^i_{jkl} \circ \Phi)}{\partial t}(t, X_p) = \lim_{h \rightarrow 0} \frac{\mathbf{R}^i_{jkl}(\Phi(t+h, X_p)) - \mathbf{R}^i_{jkl}(\Phi(t, X_p))}{h}.$$

Let \mathcal{R} be the tensor

$$\mathcal{R}(X, Y, Z, W) = \langle R(X, Y)Z, W \rangle,$$

so that (c.f. pg. II.277)

$$\mathbf{R}^i_{jkl} = \mathcal{R}(X_k, X_l, X_j, X_i).$$

Since $\Phi(t, X_p) = \exp(tX_p)$, and since the X_i are defined by parallel translating the X_{ip} along geodesics, equation (1) can be written

$$\begin{aligned} & \frac{\partial(\mathbf{R}^i_{jkl} \circ \Phi)}{\partial t}(t, X_p) \\ &= (\nabla_{X(\Phi(t, X_p))} \mathcal{R})(X_k(\Phi(t, X_p)), X_l(\Phi(t, X_p)), X_j(\Phi(t, X_p)), X_i(\Phi(t, X_p))) \\ &= (\nabla \mathcal{R})(X_k(\Phi(t, X_p)), X_l(\Phi(t, X_p)), X_j(\Phi(t, X_p)), X_i(\Phi(t, X_p)), X(\Phi(t, X_p))), \end{aligned}$$

where X is also defined by parallel translating X_p along geodesics. In general, we have

$$\begin{aligned} & \frac{\partial^d(\mathbf{R}^i_{jkl} \circ \Phi)}{\partial t^d}(t, X_p) \\ &= (\overbrace{\nabla \cdots \nabla}^d \mathcal{R})(X_k(\Phi(t, X_p)), \dots, X_i(\Phi(t, X_p)), \overbrace{X(\Phi(t, X_p)), \dots, X(\Phi(t, X_p))}^d). \end{aligned}$$

In particular,

$$\frac{\partial^d (\mathbf{R}^i_{jkl} \circ \Phi)}{\partial t^d} (0, X_p) = (\nabla^d \mathcal{R})(X_{pk}, X_{pl}, X_{pj}, X_{pi}, \overbrace{X_p, \dots, X_p}^d).$$

Thus, in the analytic case, the metric in normal coordinates around p is determined completely by knowing all $\nabla^d \mathcal{R}$ at p .

Thus we have a criterion for deciding when some neighborhood of a given point $p \in M$ can be taken isometrically onto a neighborhood of a point $\bar{p} \in \bar{M}$. This criterion works only for analytic metrics, but its real defect is the fact that we have to compute infinitely many quantities $(\nabla^d \mathcal{R})(p)$. Now we will explain how one can decide whether some open set in M is isometric to some open set of \bar{M} , without being given points p, \bar{p} in advance, without assuming the metric is analytic, and by computing only finitely many covariant derivatives $\nabla^d \mathcal{R}$. True, we will have to compute the $\nabla^d \mathcal{R}$ on all of M , not just at one point p , but in practice the only way to compute the $(\nabla^d \mathcal{R})(p)$ is to compute the $\nabla^d \mathcal{R}$ in a whole coordinate system anyway.

First we consider a general problem having nothing to do with metrics. Suppose we are given two manifolds M^N and \bar{M}^N of the same dimension N . Let $\omega^1, \dots, \omega^N$ be N everywhere linearly independent 1-forms on (a subset of) M , and let $\bar{\omega}^1, \dots, \bar{\omega}^N$ be similar 1-forms on \bar{M} . We will find a way of deciding when there is locally a diffeomorphism $\alpha: M \rightarrow \bar{M}$ such that $\omega^i = \alpha^* \bar{\omega}^i$ for $i = 1, \dots, N$. First of all, let us write

$$\begin{aligned} d\omega^i &= \sum_{j < k} C_{jk}^i \omega^j \wedge \omega^k \\ d\bar{\omega}^i &= \sum_{j < k} \bar{C}_{jk}^i \bar{\omega}^j \wedge \bar{\omega}^k \end{aligned}$$

for certain functions C_{jk}^i and \bar{C}_{jk}^i . If α exists, then we will have $C_{jk}^i = \bar{C}_{jk}^i \circ \alpha$. Now suppose that among the functions C_{jk}^i there are N which form a coordinate system (u_1, \dots, u_N) on M . Then if α exists, the corresponding N functions \bar{C}_{jk}^i must form a coordinate system $(\bar{u}_1, \dots, \bar{u}_N)$ on \bar{M} . In this case, the diffeomorphism α must be

$$(1) \quad \alpha = (\bar{u}_1, \dots, \bar{u}_N)^{-1} \circ (u_1, \dots, u_N).$$

For this α we certainly have

$$(2) \quad C_{jk}^i = \bar{C}_{jk}^i \circ \alpha$$

when C_{jk}^i is one of the u 's, and we may add the extra condition that equation (2) hold in all cases. [In the "general" case, the other C_{jk}^i will be functions of the u 's,

$$C_{jk}^i = f_{jk}^i \circ (u_1, \dots, u_N),$$

so we are demanding that the other \bar{C}_{jk}^i be the same functions of the \bar{u} 's.] We still have to decide when α given by (1) is the required diffeomorphism. For this we write

$$\begin{aligned} dC_{jk}^i &= \sum_l C_{jk,l}^i \omega^l \\ d\bar{C}_{jk}^i &= \sum_l \bar{C}_{jk,l}^i \bar{\omega}^l \end{aligned}$$

for certain functions $C_{jk,l}^i$ and $\bar{C}_{jk,l}^i$. If α has the desired properties, then we must also have

$$(3) \quad C_{jk,l}^i = \bar{C}_{jk,l}^i \circ \alpha.$$

Conversely, suppose equation (3) holds. Then

$$\begin{aligned} (4) \quad \sum_l C_{jk,l}^i \cdot (\omega^l - \alpha^* \bar{\omega}^l) &= \sum_l C_{jk,l}^i \omega^l - \sum_l (\bar{C}_{jk,l}^i \circ \alpha) \cdot \alpha^* \bar{\omega}^l \\ &= \sum_l C_{jk,l}^i \omega^l - \alpha^* \left(\sum_l \bar{C}_{jk,l}^i \cdot \bar{\omega}^l \right) \\ &= dC_{jk}^i - \alpha^*(d\bar{C}_{jk}^i) \\ &= dC_{jk}^i - d(\bar{C}_{jk}^i \circ \alpha) \\ &= 0 \quad \text{by (2).} \end{aligned}$$

This is a set of N^3 equations in N unknowns. It can be written in terms of the $N^3 \times N$ matrix $(C_{jk,l}^i)$ in which l denotes the column, and $_{jk}^i$ denotes the row. This matrix contains the $N \times N$ submatrix $(u_{i,l})$, which is non-singular, since (u_1, \dots, u_N) is a coordinate system. So the matrix $(C_{jk,l}^i)$ has rank N . This means that the only solution of our equations is the zero solution. Thus, $\omega^l = \alpha^* \bar{\omega}^l$ for $l = 1, \dots, N$.

Suppose, on the contrary, that we can choose only $N_1 < N$ functions C_{jk}^i which are independent (meaning that for any coordinate system x^1, \dots, x^N , the $N_1 \times N$ matrix $(\partial C_{jk}^i / \partial x^l)$ has rank N_1 ; or equivalently, that the $N_1 \times N$ matrix $(C_{jk,l}^i)$ has rank N_1). We now look at the functions $C_{jk,l}^i$. Among these we may

be able to choose N_2 functions $C_{jk,l}^i$ which together with the N_1 functions C_{jk}^i are independent. If $N_1 + N_2 < N$, then we look at the functions $C_{jk,lm}^i$ defined by

$$dC_{jk,l}^i = \sum_m C_{jk,lm}^i \omega^m.$$

Among these we may be able to pick N_3 which can be added to the $N_1 + N_2$ functions already obtained. Suppose that, after continuing in this way, we eventually obtain $N_1 + \dots + N_\mu = N$ independent functions. Then we can determine what α must be; moreover, we can decide whether this α really works by seeing if α satisfies

$$C_{jk,l_1 \dots l_{\mu+1}}^i = \bar{C}_{jk,l_1 \dots l_{\mu+1}}^i \circ \alpha.$$

On the other hand, it may happen that we never obtain N independent functions. In the general case this will happen because at some stage, the functions

$$C_{jk,l_1 \dots l_{\mu+1}}^i$$

are all functions of the previously chosen functions. [Notice that once this happens at stage μ , it will happen at all later stages. So in general, the integers N_1, N_2, \dots which we picked in the previous case are all ≥ 1 . Thus we either obtain N independent functions in $\leq N$ stages, or we arrive at the present situation in $\leq N$ stages.] We now have $N' = N_1 + \dots + N_\mu < N$ independent functions. If α exists, then it must satisfy the N' equations

$$(*) \quad \begin{cases} C_{jk}^i = \bar{C}_{jk}^i \circ \alpha \\ \vdots \\ C_{jk,l_1, \dots, l_\mu}^i = \bar{C}_{jk,l_1, \dots, l_\mu}^i \circ \alpha. \end{cases}$$

In the same way that we obtained equations (4), we can use equations (*) to deduce N' linear equations for $\omega^1 - \bar{\omega}^1, \dots, \omega^N - \bar{\omega}^N$. Moreover, the rank of the matrix for these equations is N' , so we can solve for $N - N'$ of the unknowns in terms of the other N' . Without loss of generality, we can assume that these equations can be solved for the last $N - N'$ of the $\omega^i - \bar{\omega}^i$ in terms of the first N' of the $\omega^i - \bar{\omega}^i$. Then clearly the diffeomorphism α has the desired properties if it satisfies (*) as well as

$$(**) \quad \omega^i = \alpha^* \bar{\omega}^i, \quad i = 1, \dots, N'.$$

We claim that there are always such diffeomorphisms α , in fact, an $(N - N')$ -parameter family of them. To prove this, we look for the graph of α , as a subset

of $M \times \bar{M}$. Let $\pi: M \times \bar{M} \rightarrow M$ and $\bar{\pi}: M \times \bar{M} \rightarrow \bar{M}$ be the projections. Since the C_{jk}^i, \dots and \bar{C}_{jk}^i, \dots in (*) are independent functions, the set

$$\mathcal{M} = \{x \in M \times \bar{M} : C_{ij} \circ \pi(x) = \bar{C}_{jk}^i \circ \bar{\pi}(x), \dots\}$$

is a submanifold, of dimension $2N - N'$. We will denote the restrictions of $\pi^*\omega^i$ and $\bar{\pi}^*\bar{\omega}^i$ to \mathcal{M} simply by $\pi^*\omega^i$ and $\bar{\pi}^*\bar{\omega}^i$. Consider the ideal \mathcal{I} of forms on \mathcal{M} generated by the 1-forms

$$\pi^*\omega^i - \bar{\pi}^*\bar{\omega}^i, \quad i = 1, \dots, N'.$$

We have

$$\begin{aligned} d(\pi^*\omega^i - \bar{\pi}^*\bar{\omega}^i) &= \sum (C_{jk}^i \circ \pi) \pi^*\omega^j \wedge \pi^*\omega^k - \sum (\bar{C}_{jk}^i \circ \bar{\pi}) \bar{\pi}^*\bar{\omega}^j \wedge \bar{\pi}^*\bar{\omega}^k \\ &= \sum (C_{jk}^i \circ \pi) [\pi^*\omega^j \wedge \pi^*\omega^k - \bar{\pi}^*\bar{\omega}^j \wedge \bar{\pi}^*\bar{\omega}^k] \quad (\text{on } \mathcal{M}) \\ &= \sum (C_{jk}^i \circ \pi) [(\pi^*\omega^j \wedge \bar{\pi}^*\bar{\omega}^i) \wedge \pi^*\omega^k \\ &\quad - \bar{\pi}^*\bar{\omega}^i \wedge (\pi^*\omega^j - \bar{\pi}^*\bar{\omega}^j)], \end{aligned}$$

which is in \mathcal{I} . Thus there is a submanifold \mathcal{M}' of \mathcal{M} on which the forms $\pi^*\omega^i - \bar{\pi}^*\bar{\omega}^i$ all vanish. This submanifold \mathcal{M}' has dimension $(2N - N') - N' = 2(N - N')$. There is an $(N - N')$ -parameter family of N -dimensional submanifolds \mathcal{M}'' of \mathcal{M}' which project one-one onto M . Each of these is the graph of an appropriate α .

Finally, let us return to the case of two Riemannian manifolds M^n and \bar{M}^n . We immediately pass to the principal bundles $O(TM)$ and $O(T\bar{M})$ of orthonormal frames. On these bundles we have forms $\theta = (\theta^i)$, $\omega = (\omega_j^i)$ and $\bar{\theta} = (\bar{\theta}^i)$, $\bar{\omega} = (\bar{\omega}_j^i)$. Recall that for $u = (u_1, \dots, u_n) \in O(TM)$ and a tangent vector $Y \in O(TM)_u$, we have

$$\pi_* Y_u = \sum_{i=1}^n \theta^i(Y_u) \cdot u_i,$$

where $\pi: O(TM) \rightarrow M$ is the projection map. In particular, $\theta(Y_u) = 0$ if and only if $\pi_* Y_u = 0$. Now any isometry $\alpha: M \rightarrow \bar{M}$ gives rise to a diffeomorphism $\tilde{\alpha}: O(TM) \rightarrow O(T\bar{M})$, and $\tilde{\alpha}^*\bar{\theta} = \theta$, $\tilde{\alpha}^*\bar{\omega} = \omega$. Conversely, suppose we have a diffeomorphism $\beta: O(TM) \rightarrow O(T\bar{M})$ with $\beta^*\bar{\theta} = \theta$. If c is any curve in the fibre of $O(TM)$ at p , then for all t we have $\pi_* c'(t) = 0$, and thus

$$\begin{aligned} 0 &= \theta(c'(t)) = \beta^*\bar{\theta}(c'(t)) \\ &= \bar{\theta}(\beta_* c'(t)) \\ \implies 0 &= \bar{\pi}_* \beta_* c'(t) = (\bar{\pi} \circ \beta \circ c)'(t). \end{aligned}$$

Thus $\bar{\pi} \circ \beta \circ c$ is constant. This shows that β takes fibres to fibres, so there is a map $\alpha: M \rightarrow \bar{M}$ with $\bar{\pi} \circ \beta = \alpha \circ \pi$. Moreover, if $u = (u_1, \dots, u_n) \in O(TM)$ and $Y_u \in O(TM)_u$ satisfies $\pi_* Y_u = u_j$, then $\theta^i(Y_u) = \delta_j^i$, so

$$\begin{aligned} \delta_j^i &= \beta^* \bar{\theta}^i(Y_u) \\ &= \bar{\theta}^i(\beta_* Y_u) \\ &= i^{\text{th}} \text{ component of } \bar{\pi}_* \beta_* Y_u \text{ with respect to } \beta(u) \\ &= \text{''} \quad \text{''} \quad \text{''} \alpha_* \pi_* Y_u \quad \text{''} \quad \text{''} \quad \text{''} \beta(u) \\ &= \text{''} \quad \text{''} \quad \text{''} \alpha_*(u_j) \quad \text{''} \quad \text{''} \quad \text{''} \beta(u). \end{aligned}$$

Thus β must be

$$\beta(u) = (\alpha_* u_1, \dots, \alpha_* u_n),$$

i.e., $\beta = \tilde{\alpha}$. In particular, α is an isometry. Thus we see that the existence of an isometry $\alpha: M \rightarrow \bar{M}$ is equivalent to the existence of a diffeomorphism $\beta: O(TM) \rightarrow O(T\bar{M})$ such that $\beta^* \bar{\theta}^i = \theta^i$. Hence it is also equivalent to the existence of a diffeomorphism $\beta: O(TM) \rightarrow O(T\bar{M})$ such that $\beta^* \bar{\theta}^i = \theta^i$ and $\beta^* \bar{\omega}_j^i = \omega_j^i$. We have just seen how to decide whether such a β exists, since the θ^i and ω_j^i are everywhere linearly independent and span the 1-forms, and similarly for the $\bar{\theta}^i$ and $\bar{\omega}_j^i$. The first step is to compute the $d\theta^i$ and $d\omega_j^i$ in terms of the θ^i and ω_j^i . We already have the structural equations (pg. II.329),

$$(1) \quad d\theta^i = - \sum_j \omega_j^i \wedge \theta^j$$

$$\begin{aligned} (2) \quad d\omega_j^i &= - \sum_k \omega_k^i \wedge \omega_j^k + \Omega_j^i \\ &= - \sum_k \omega_k^i \wedge \omega_j^k - \sum_{k < l} A_{ijkl} \theta^k \wedge \theta^l, \quad \text{say.} \end{aligned}$$

These functions A_{ijkl} are the first set which we have to examine. Now if $s = (X_1, \dots, X_n)$ is an orthonormal moving frame, then its dual forms and connection forms are $\theta^i = s^* \bar{\theta}^i$ and $\omega_j^i = s^* \bar{\omega}_j^i$. So s^* of equation (2) gives

$$d\omega_j^i = - \sum_k \omega_k^i \wedge \omega_j^k - \sum_{k < l} (A_{ijkl} \circ s) \theta^k \wedge \theta^l.$$

On the other hand, we have

$$\begin{aligned} d\omega_j^i &= - \sum_k \omega_k^i \wedge \omega_j^k + \Omega_j^i \\ &= - \sum_k \omega_k^i \wedge \omega_j^k + \sum_{k < l} \langle R(X_k, X_l) X_j, X_i \rangle \theta^k \wedge \theta^l. \end{aligned}$$

Thus we see that

$$A_{ijkl}(u) = -\langle R(u_k, u_l)u_j, u_i \rangle = \mathcal{R}(u_i, u_j, u_k, u_l).$$

The next set of functions which we need to look at are those appearing in the expansion

$$dA_{ijkl} = \sum_{\mu, \nu} (\quad) \omega_\nu^\mu + \sum_{\mu} A_{ijkl, \mu} \theta^\mu.$$

Taking s^* of this equation, and evaluating at a tangent vector X of M , we get

$$\begin{aligned} X(\mathcal{R}(X_i, X_j, X_k, X_l)) &= X(A_{ijkl} \circ s) = d(A_{ijkl} \circ s)(X) = s^*(dA_{ijkl})(X) \\ &= \sum_{\mu, \nu} [(\quad) \circ s] \omega_\nu^\mu(X) + \sum_{\mu} [A_{ijkl, \mu} \circ s] \theta^\mu(X). \end{aligned}$$

Since

$$\begin{aligned} X(\mathcal{R}(X_i, X_j, X_k, X_l)) &= (\nabla \mathcal{R})(X_i, X_j, X_k, X_l, X) \\ &\quad + \mathcal{R}(\nabla_X X_i, \dots) + \mathcal{R}(X_i, \nabla_X X_j, \dots) + \dots, \end{aligned}$$

we see that we must have

$$dA_{ijkl} = \sum_{\mu} A_{\mu jkl} \omega_i^\mu + \dots + \sum_{\mu} A_{ijk\mu} \omega_l^\mu + \sum_{\mu} A_{ijkl, \mu} \theta^\mu,$$

where

$$A_{ijkl, \mu}(u) = (\nabla \mathcal{R})(u_i, u_j, u_k, u_l, u_\mu).$$

Similarly, we get

$$dA_{ijkl, \mu} = \sum_{\nu} A_{\nu jkl, \mu} \omega_i^\nu + \dots + \sum_{\nu} A_{ijk\nu, \mu} \omega_l^\nu + \sum_{\nu} A_{ijkl, \nu} \omega_\mu^\nu + \sum_{\nu} A_{ijkl, \mu\nu} \theta^\nu,$$

where

$$A_{ijkl, \mu\nu}(u) = (\nabla \nabla \mathcal{R})(u_i, u_j, u_k, u_l, u_\mu, u_\nu),$$

and so on. So we see that after computing a finite number of the functions $\mathcal{R}, \nabla \mathcal{R}, \nabla \nabla \mathcal{R}, \dots$ we can finally decide if the desired isometry α exists (provided we can keep track of what in the world we are doing, which doesn't seem very likely).

ADDENDUM 4

BETTER IMBEDDING INVARIANTS

There is a theory, due to Burstin, Mayer, and Allendoerfer, which shows that certain tensors are a complete set of invariants for submanifolds $M^n \subset N^m$ of a manifold N of constant curvature. (As in the theory of curves, we have to impose certain conditions on M , which say, roughly speaking, that at each point M bends in the same number of directions.) One almost never sees any applications of this theory nowadays, but perhaps that is partly because the classical expositions make it so inaccessible. In our presentation, we will first consider a special case of the general problem, so as not to be overwhelmed with details at the beginning.

For a Riemannian manifold $(M, \langle \cdot, \cdot \rangle)$, the “Fundamental Lemma of Riemannian geometry” tells us that there is a unique connection ∇ on TM which is compatible with the metric and also symmetric. The following Lemma gives, under certain conditions, an analogous characterization of the normal connection D on the normal bundle $\text{Nor } M$ of M in N .

65. LEMMA. Let $M \subset N$ have normal bundle $\text{Nor } M$ and second fundamental form s . Suppose that $s: M_p \times M_p \rightarrow M_p^\perp$ is onto for all p . Then the normal connection D in $\text{Nor } M$ is the unique connection δ such that

(1) δ is compatible with the metric in $\text{Nor } M$:

$$X(\langle \xi, \eta \rangle) = \langle \delta_X \xi, \eta \rangle + \langle \xi, \delta_X \eta \rangle \quad \text{for sections } \xi, \eta \text{ of } \text{Nor } M,$$

(2) δ satisfies the Codazzi-Mainardi equations:

$$\begin{aligned} \perp(R'(X, Y)Z) &= [\delta_X(s(Y, Z)) - s(\nabla_X Y, Z) - s(Y, \nabla_X Z)] \\ &\quad - [\delta_Y(s(X, Z)) - s(\nabla_Y X, Z) - s(X, \nabla_Y Z)]. \end{aligned}$$

PROOF. Consider the expression

$$\begin{aligned} &\langle \delta_X s(Y_1, Y_2), s(Z_1, Z_2) \rangle - \langle \delta_{Y_1} s(X, Y_2), s(Z_1, Z_2) \rangle \\ &\quad - \langle \delta_{Y_1} s(Z_1, Z_2), s(X, Y_2) \rangle + \langle \delta_{Z_1} s(Y_1, Z_2), s(X, Y_2) \rangle \\ &\quad + \langle \delta_{Z_1} s(X, Y_2), s(Y_1, Z_2) \rangle - \langle \delta_X s(Z_1, Y_2), s(Y_1, Z_2) \rangle. \end{aligned}$$

Condition (2) shows that each row can be expressed in terms of the vector fields X, Y_i, Z_i . But condition (1) shows that the sum of the two terms involving δ_{Y_1} or δ_{Z_1} can also be expressed in this way. Thus we can write

$$(3) \quad \langle \delta_X s(Y_1, Y_2), s(Z_1, Z_2) \rangle - \langle \delta_X s(Z_1, Y_2), s(Y_1, Z_2) \rangle = \dots,$$

where ... can be expressed in terms of the vector fields. So we have as well

$$(3') \quad \langle \delta_X s(Y_2, Z_1), s(Z_2, Y_1) \rangle - \langle \delta_X s(Z_2, Z_1), s(Y_2, Y_1) \rangle = \dots$$

Adding (3) and (3'), we obtain

$$(4) \quad \langle \delta_X s(Y_1, Y_2), s(Z_1, Z_2) \rangle - \langle \delta_X s(Z_1, Z_2), s(Y_1, Y_2) \rangle = \dots$$

But by (1) we also have

$$(5) \quad \langle \delta_X s(Y_1, Y_2), s(Z_1, Z_2) \rangle + \langle \delta_X s(Z_1, Z_2), s(Y_1, Y_2) \rangle = \dots$$

So by adding (4) and (5) we obtain

$$\langle \delta_X s(Y_1, Y_2), s(Z_1, Z_2) \rangle = \dots$$

Since $s: M_p \times M_p \rightarrow M_p^\perp$ is onto, this shows that $\delta_X s(Y_1, Y_2)$ is uniquely determined by X_p, Y_1, Y_2 . Since every section of $\text{Nor } M$ is a linear combination, over the C^∞ functions, of sections of the form $s(Y_1, Y_2)$, this shows that δ is uniquely determined. ♦

Remark: Naturally we are mainly interested in the case where N has constant curvature, in which case the left side of (2) is 0. Now given any bundle $\varpi: E \rightarrow M$ with a metric $\langle \cdot, \cdot \rangle$, and a symmetric section s of $\text{Hom}(TM \times TM, E)$, we can consider the “Codazzi-Mainardi equations”

$$\begin{aligned} [\delta_X(s(Y, Z)) - s(\nabla_X Y, Z) - s(Y, \nabla_X Z)] = \\ [\delta_Y(s(X, Z)) - s(\nabla_Y X, Z) - s(X, \nabla_Y Z)]. \end{aligned}$$

The proof of Lemma 65 shows that if $s: M_p \times M_p \rightarrow \varpi^{-1}(p)$ is always onto, then there is at most one δ compatible with $\langle \cdot, \cdot \rangle$ which satisfies this equation. However, there may not be any such δ (unless s is always one-one).

Now for a submanifold $M \subset N$ we will denote the induced metric $\langle \cdot, \cdot \rangle$ on M by \mathcal{F}_0 , and define a tensor \mathcal{F}_1 by

$$\mathcal{F}_1(X_1, X_2, Y_1, Y_2) = \langle s(X_1, X_2), s(Y_1, Y_2) \rangle.$$

66. PROPOSITION. Let $M, \bar{M} \subset N$ be connected submanifolds of a complete simply-connected manifold N of constant curvature. Suppose that the second fundamental forms $s: M_p \times M_p \rightarrow M_p^\perp$ and $\bar{s}: \bar{M}_q \times \bar{M}_q \rightarrow \bar{M}_q^\perp$ are onto at all points. Let $\phi: M \rightarrow \bar{M}$ be a diffeomorphism such that

$$\phi^* \bar{\mathcal{F}}_0 = \mathcal{F}_0 \quad \text{and} \quad \phi^* \bar{\mathcal{F}}_1 = \mathcal{F}_1.$$

Then ϕ is the restriction of an isometry of N .

PROOF. First of all, since $\phi^* \bar{\mathcal{F}}_0 = \mathcal{F}_0$, we have

$$(1) \quad \phi_*(\nabla_X Y) = \bar{\nabla}_{\phi_* X} \phi_* Y.$$

Now let $\{X_\alpha\}$ be any set of vectors in M_p which span M_p , and let $\bar{X}_\alpha = \phi_*(X_\alpha) \in \bar{M}_{f(p)}$. Consider the vectors $s(X_\alpha, X_\beta) \in M_p^\perp$, and the corresponding vectors $\bar{s}(\bar{X}_\alpha, \bar{X}_\beta) \in \bar{M}_{f(p)}^\perp$. By hypothesis, we have

$$\langle s(X_\alpha, X_\beta), s(X_\gamma, X_\delta) \rangle = \langle \bar{s}(\bar{X}_\alpha, \bar{X}_\beta), \bar{s}(\bar{X}_\gamma, \bar{X}_\delta) \rangle.$$

Since the second fundamental forms are onto M_p^\perp and $\bar{M}_{f(p)}^\perp$, this implies (Problem 25) that there is a unique inner product preserving isomorphism $M_p^\perp \rightarrow \bar{M}_{f(p)}^\perp$ which takes $s(X_\alpha, X_\beta)$ to $\bar{s}(\bar{X}_\alpha, \bar{X}_\beta)$. This isomorphism cannot depend on the $\{X_\alpha\}$, for if we also have spanning vectors $\{Y_\alpha\}$, we can consider the set $\{X_\alpha\} \cup \{Y_\alpha\}$.

By applying this construction for all $p \in M$, we obtain a bundle isomorphism $\tilde{\phi}: \text{Nor } M \rightarrow \text{Nor } \bar{M}$ covering ϕ such that $\tilde{\phi}$ preserves inner products and second fundamental forms:

$$(2) \quad \langle \tilde{\phi}(\xi), \tilde{\phi}(\eta) \rangle = \langle \xi, \eta \rangle \quad \text{for sections } \xi, \eta \text{ of } \text{Nor } M$$

$$(3) \quad \tilde{\phi}(s(X, Y)) = \bar{s}(\phi_* X, \phi_* Y).$$

We claim that $\tilde{\phi}$ also preserves the normal connections:

$$(4) \quad \tilde{\phi}(D_X \xi) = \bar{D}_{\phi_* X}(\tilde{\phi}(\xi)).$$

To prove this we note that since every section of $\text{Nor } \bar{M}$ is uniquely of the form $\tilde{\phi}(\xi)$, and every tangent vector of \bar{M} is uniquely of the form $\phi_* X$, we can define a connection δ on $\text{Nor } \bar{M}$ with

$$\delta_{\phi_* X}(\tilde{\phi}(\xi)) = \tilde{\phi}(D_X \xi).$$

Now the connection D is compatible with the metric and satisfies the Codazzi-Mainardi equations; applying the equations (1)–(3), we find that δ is compatible with the metric and satisfies the Codazzi-Mainardi equations (for \bar{M}). Hence $\delta = \bar{D}$, by Lemma 65. This proves (4).

The desired result now follows from Theorem 20. ♦

When we have a manifold $M \subset N$ whose second fundamental form does not fill up the normal bundle, we will have to differentiate more times, precisely as in the case of curves. Notice that the subspace of N_p spanned by M_p and

$s_p(M_p \times M_p) \subset M_p^\perp$ can also be described as the space spanned by all X_p and $\nabla'_{X_p} Y$ for vector fields X, Y on M . But we can also consider $\nabla'_{X_p}(\nabla'_Y Z)$, etc., and thereby obtain more vectors in N_p . To simplify the notation, we will write

$$\begin{aligned}\nabla'(X, Y) &= \nabla'_X Y \\ \nabla'(X, Y, Z) &= \nabla'_X(\nabla'_Y Z), \quad \text{etc.}\end{aligned}$$

We define the k^{th} **osculating space** $\text{Osc}^k M_p \subset N_p$ of M at p to be the subspace of N_p which is spanned by all

$$X_1(p), \nabla'(X_1, X_2)(p), \dots, \nabla'(X_1, \dots, X_k)(p),$$

for vector fields X_1, \dots, X_k on M . Thus the 1st osculating space $\text{Osc}^1 M_p$ is just M_p . It will also be convenient to define $\text{Osc}^0 M_p$ to be the $\{0\}$ subspace of M_p .

A submanifold $M \subset N$ will be called **nicely curved** if the dimension of each osculating space $\text{Osc}^k M_p$ is the same for all $p \in M$. (A curve c in N is nicely curved if and only if it has the property that if some curvature function κ_k is non-zero at one point, then κ_k is non-zero everywhere.) Henceforth we will consider only nicely curved submanifolds $M \subset N$. It is easy to see that for each k we then have a vector bundle $\text{Osc}^k M$ over M , whose fibre over p is $\text{Osc}^k M_p$. If ξ is a smooth section of $\text{Osc}^k M$, then ξ is locally a sum of terms $f \cdot \nabla'(X_1, \dots, X_r)$ for smooth f and X_i , and $r \leq k$. Since

$$\nabla'_X(f \nabla'(X_1, \dots, X_r)) = X(f) \cdot \nabla'(X_1, \dots, X_r) + f \cdot \nabla'(X, X_1, \dots, X_r),$$

we see that

$$(*) \quad \xi \text{ a section of } \text{Osc}^k M \implies \nabla'_{X_p} \xi \in \text{Osc}^{k+1} M_p.$$

It is easy to see that if $\text{Osc}^k M = \text{Osc}^{k+1} M$, then also $\text{Osc}^{k+1} M = \text{Osc}^{k+2} M = \dots$. So there is some $\ell \geq 1$ with

$$\text{Osc}^0 M \subsetneq \text{Osc}^1 M \subsetneq \dots \subsetneq \text{Osc}^\ell M = \text{Osc}^{\ell+1} M = \dots$$

The letter ℓ will always have this significance. Notice that $\text{Osc}^\ell M_p$ need not be all of N_p ; the dimension of $\text{Osc}^\ell M_p$ (for any $p \in M$) will be called the **formal imbedding number** $\#(M)$ of M .

67. PROPOSITION. If $M \subset N$ is nicely curved, then the distribution $p \mapsto \text{Osc}^\ell M_p$ on M is parallel along every curve in M (as defined on page 28).

Consequently, if N is a manifold of constant curvature, and M is connected, then M is contained in some $\#(M)$ -dimensional totally geodesic submanifold of N (but not in any lower dimensional totally geodesic submanifold).

PROOF. To prove the first part, it obviously suffices to work locally. In a neighborhood U of any point $p \in M$ we can choose smooth linearly independent sections $\xi_1, \dots, \xi_{\#(M)}$ of $\text{Osc}^\ell M$. For a curve c in U , let V_μ be the vector field along c given by $V_\mu(t) = \xi_\mu(c(t))$. Then $(*)$ says that

$$\frac{D'V_\mu}{dt} \in \text{Osc}^{l+1} M_{c(t)} = \text{Osc}^l M_{c(t)};$$

thus there are smooth functions $f_{\mu\nu}$ such that

$$\frac{D'V_\mu}{dt} = \sum_\nu f_{\mu\nu} V_\nu.$$

Now let W be any vector field along c with $D'W/dt = 0$. Then

$$\begin{aligned} \frac{d}{dt} \langle W, V_\mu \rangle &= \left\langle \frac{D'W}{dt}, V_\mu \right\rangle + \left\langle W, \frac{D'V_\mu}{dt} \right\rangle \\ &= \langle 0, V_\mu \rangle + \left\langle W, \sum_\nu f_{\mu\nu} V_\nu \right\rangle \\ &= \sum_\nu f_{\mu\nu} \langle W, V_\nu \rangle. \end{aligned}$$

This is a system of differential equations for the functions $\langle W, V_\mu \rangle$. One solution is $\langle W, V_\mu \rangle = 0$ for all μ . So by uniqueness of solutions we see that if $W(0)$ is perpendicular to $\text{Osc}^\ell M_{c(0)}$, then $W(t)$ is perpendicular to $\text{Osc}^\ell M_{c(t)}$ for all t . This proves that $\text{Osc}^\ell M$ is parallel along c .

The second part follows from Corollary 11. ♦

We now define the k^{th} **normal space** $\text{Nor}^k M_p$ of M at p to be the orthogonal complement of $\text{Osc}^k M_p$ in $\text{Osc}^{k+1} M_p$. Thus we have

$$\text{Osc}^{k+1} M_p = \text{Osc}^k M_p \oplus \text{Nor}^k M_p.$$

Notice that $\text{Nor}^0 M_p$ is just M_p , while $\text{Nor}^k M_p$ has dimension 0 for $k \geq \ell - 1$. It will also be convenient to let $\text{Nor}^{-1} M_p$ be the $\{0\}$ subspace of M_p . Each $\text{Nor}^k M_p \subset N_p$ has an orthogonal complement in N_p , and thus we have two projections

$$\mathbb{T}^k : N_p \rightarrow \text{Nor}^k M_p$$

$$\mathbb{L}^k : N_p \rightarrow \text{orthogonal complement of } \text{Nor}^k M_p \text{ in } N_p.$$

Notice that $\mathsf{T}^0 = \mathsf{T}: N_p \rightarrow M_p$ and $\mathsf{L}^0 = \mathsf{L}: N_p \rightarrow M_p^\perp$ (but note that T^k goes into a subspace of M_p^\perp for $k > 0$). We shall actually use only the projections T^k .

For nicely curved $M \subset N$ we clearly have, for each k , a vector bundle $\text{Nor}^k M$ whose fibre at p is $\text{Nor}^k M_p$. The bundle $\text{Nor}^0 M$ is just the tangent bundle TM , while the bundles $\text{Nor}^k M$ for $k > 0$ are all subbundles of the normal bundle $\text{Nor} M$. There are natural Riemannian metrics $\langle \cdot, \cdot \rangle$ on all bundles $\text{Nor}^k M$, since they are all subbundles of $(TN)|_M$.

The 1st normal space $\text{Nor}^1 M_p$ is the subspace of N_p spanned by all $s(X_p, Y_p)$ for $X_p, Y_p \in M_p$. In general, given vector fields X_1, \dots, X_{k+1} on M , consider

$$\mathsf{T}^k(\nabla'(X_1, \dots, X_{k+1})).$$

It is easily checked that this expression is linear in each X_i over the C^∞ functions (compare pg. III.4). So its value at p depends only on the values of the X_i at p and we can define

$$s^k(X_{1p}, \dots, X_{k+1p}) = \mathsf{T}^k(\nabla'(X_1, \dots, X_{k+1})(p)) \in \text{Nor}^k M_p$$

for any vector fields X_i extending X_{ip} . Clearly $\text{Nor}^k M_p$ is spanned by the image of s^k . It seems reasonable to let s^0 denote the identity map of M_p into $\text{Nor}^0 M_p = M_p$.

68. LEMMA. If $M \subset N$, where N has constant curvature, then s^k is symmetric.

PROOF. First we have

$$\begin{aligned} \nabla'(X_1, \dots, X_k, X_{k+1})(p) - \nabla'(X_1, \dots, X_{k+1}, X_k)(p) \\ = \nabla'(X_1, \dots, X_{k-1}, [X_k, X_{k+1}])(p) \in \text{Osc}^k M_p, \end{aligned}$$

so T^k of the left side is 0, which proves that s^k is symmetric in X_k and X_{k+1} . We also have, for example,

$$\begin{aligned} \nabla'(X_1, \dots, X_{k-1}, X_k, X_{k+1})(p) - \nabla'(X_1, \dots, X_k, X_{k-1}, X_{k+1})(p) \\ = \nabla'(X_1, \dots, X_{k-2}, \nabla'_{X_{k-1}}(\nabla'_{X_k} X_{k+1}) - \nabla'_{X_k}(\nabla'_{X_{k-1}} X_k))(p) \\ = \nabla'(X_1, \dots, X_{k-2}, \nabla'_{[X_{k-1}, X_k]} X_{k+1} + R'(X_{k-1}, X_k) X_{k+1})(p). \end{aligned}$$

Since $R'(X_{k-1}, X_k) X_{k+1}$ is tangent to M , this is in $\text{Osc}^{k-1} M_p$, so again T^k of the left side is 0. Similarly, s^k is symmetric under interchange of any two adjacent arguments. ♦

For vector fields X_1, \dots, X_{k+1} on a nicely curved submanifold $M \subset N$ we can write

$$s^k(X_1, \dots, X_{k+1}) = \nabla'(X_1, \dots, X_{k+1}) + \xi, \quad \xi \text{ a section of } \text{Osc}^k M.$$

Then

$$\mathbb{T}^{k+1} \nabla'_{X_p} s^k(X_1, \dots, X_{k+1}) = \mathbb{T}^{k+1} \nabla'_{X_p} \nabla'(X_1, \dots, X_{k+1}),$$

since $\nabla'_{X_p} \xi \in \text{Osc}^{k+1} M_p$ by (*), on page 166. Thus we have

$$(**) \quad \mathbb{T}^{k+1} \nabla'_{X_p} s^k(X_1, \dots, X_{k+1}) = s^{k+1}(X_p, X_1(p), \dots, X_{k+1}(p)).$$

Now suppose we have vector fields $\{Y_\alpha\}$ which span the tangent space of M in a neighborhood of p . Every element of $\text{Nor}^1 M_p$, for example, can be written as

$$\sum c_{\alpha\beta} \cdot s(Y_\alpha(p), Y_\beta(p)).$$

This expression is usually not unique (even if the $Y_\alpha(p)$ are linearly independent). But suppose that we have constants $c_{\alpha\beta}$ with

$$\sum c_{\alpha\beta} \cdot s(Y_\alpha(p), Y_\beta(p)) = 0.$$

Let \mathcal{J} be a collection of pairs (α, β) such that

$$\{s(X_\alpha(p), X_\beta(p)) : (\alpha, \beta) \in \mathcal{J}\}$$

is a basis of $\text{Nor}^1 M_p$. Since M is nicely curved, it follows that $\{s(X_\alpha(q), X_\beta(q)) : (\alpha, \beta) \in \mathcal{J}\}$ is a basis of $\text{Nor}^1 M_q$ for all points q in a neighborhood of p . Now consider the section

$$\sum c_{\alpha\beta} \cdot s(Y_\alpha, Y_\beta)$$

of $\text{Nor}^1 M$, where the $c_{\alpha\beta}$ denote constant functions. In a neighborhood of p we can write

$$\sum c_{\alpha\beta} \cdot s(Y_\alpha, Y_\beta) = \sum_{(\alpha, \beta) \in \mathcal{J}} f_{\alpha\beta} \cdot s(Y_\alpha, Y_\beta)$$

for *unique* smooth functions $f_{\alpha\beta}$. Clearly $f_{\alpha\beta}(p) = 0$. Applying ∇'_{X_p} to the above equation we thus obtain

$$\begin{aligned} \sum c_{\alpha\beta} \cdot \nabla'_{X_p} s(Y_\alpha, Y_\beta) &= \sum_{(\alpha, \beta) \in \mathcal{J}} X_p(f_{\alpha\beta}) \cdot s(Y_\alpha(p), Y_\beta(p)) + 0 \\ &\in \text{Nor}^1 M_p. \end{aligned}$$

Consequently,

$$0 = \sum c_{\alpha\beta} \cdot \mathbb{T}^2 \nabla'_{X_p} s(Y_\alpha, Y_\beta) = \sum c_{\alpha\beta} \cdot s(X_p, Y_\alpha(p), Y_\beta(p)) \quad \text{by (**).}$$

Thus we see that

$$\sum c_{\alpha\beta} \cdot s(Y_\alpha(p), Y_\beta(p)) = 0 \implies \sum c_{\alpha\beta} \cdot s(X_p, Y_\alpha(p), Y_\beta(p)) = 0.$$

It follows that there is a well-defined map from $\text{Nor}^1 M_p$ to $\text{Nor}^2 M_p$ under which

$$\sum c_{\alpha\beta} \cdot s(Y_\alpha(p), Y_\beta(p)) \mapsto \sum c_{\alpha\beta} \cdot s(X_p, Y_\alpha(p), Y_\beta(p)).$$

This map doesn't depend on the choice of $\{Y_\alpha\}$, for if we also have spanning vector fields $\{Z_\alpha\}$, we can apply the above argument to the collection $\{Y_\alpha\} \cup \{Z_\alpha\}$. The argument clearly works for all k , so we see that there is a well-defined bilinear map

$$\mathbf{s}^k : M_p \times \text{Nor}^k M_p \rightarrow \text{Nor}^{k+1} M_p$$

such that

$$\mathbf{s}^k(X_p, \mathbf{s}^k(X_{1p}, \dots, X_{k+1p})) = \mathbf{s}^{k+1}(X_p, X_{1p}, \dots, X_{k+1p}).$$

Now suppose we have any section ξ of $\text{Nor}^k M$. Locally ξ can be written as a sum of terms $f \cdot \mathbf{s}^k(X_1, \dots, X_{k+1})$. Since

$$\begin{aligned} \nabla'_{X_p}(f \cdot \mathbf{s}^k(X_1, \dots, X_{k+1})) &= X_p(f) \cdot \mathbf{s}^k(X_{1p}, \dots, X_{k+1p}) \\ &\quad + f(p) \cdot \nabla'_{X_p} \mathbf{s}^k(X_1, \dots, X_{k+1}), \end{aligned}$$

we see that

$$\mathbb{T}^{k+1} \nabla'_{X_p}(f \cdot \mathbf{s}^k(X_1, \dots, X_{k+1})) = f(p) \cdot \mathbb{T}^{k+1} \nabla'_{X_p} \mathbf{s}^k(X_1, \dots, X_{k+1}).$$

Then (**) shows that

$$(***) \quad \mathbb{T}^{k+1} \nabla'_{X_p} \xi = \mathbf{s}^k(X_p, \xi_p), \quad \xi \text{ a section of } \text{Nor}^k M.$$

Now we will consider all the other components of $\nabla'_{X_p} \xi$ for ξ a section of $\text{Nor}^k M$. First we note

69. LEMMA. If ξ is a section of $\text{Nor}^k M$ and $X_p \in M_p$, then

$$\nabla'_{X_p} \xi \in \text{Nor}^{k-1} M_p \oplus \text{Nor}^k M_p \oplus \text{Nor}^{k+1} M_p.$$

PROOF. Since ξ is a section of $\text{Osc}^{k+1} M$, we have $\nabla'_{X_p} \xi \in \text{Osc}^{k+2} M_p$. Now if η is any section of $\text{Osc}^j M$ for $j < k$, then $\langle \xi, \eta \rangle = 0$, so

$$0 = X_p(\langle \xi, \eta \rangle) = \langle \nabla'_{X_p} \xi, \eta(p) \rangle + \langle \xi(p), \nabla'_{X_p} \eta \rangle.$$

If we also have $j < k - 1$, then $\nabla'_{X_p} \eta \in \text{Osc}^k M_p$, so $\langle \xi(p), \nabla'_{X_p} \eta \rangle = 0$, and hence $\langle \nabla'_{X_p} \xi, \eta(p) \rangle = 0$. ♦

Thus we see that for a section ξ of $\text{Nor}^k M$ we can write

$$\nabla'_{X_p} \xi = \mathbb{T}^{k-1}(\nabla'_{X_p} \xi) + \mathbb{T}^k(\nabla'_{X_p} \xi) + \mathbb{T}^{k+1}(\nabla'_{X_p} \xi).$$

The third term of this decomposition is already given by (**). For the first term we have a result which generalizes Proposition 12.

70. PROPOSITION. If ξ is a section of $\text{Nor}^k M$ and $X_p \in M_p$, then the vector $\mathbb{T}^{k-1}(\nabla'_{X_p} \xi) \in \text{Nor}^{k-1} M_p$ satisfies

$$\begin{aligned} \langle \mathbb{T}^{k-1}(\nabla'_{X_p} \xi), \eta_p \rangle &= \langle \nabla'_{X_p} \xi, \eta_p \rangle = -\langle \xi(p), \mathbf{s}^{k-1}(X_p, \eta_p) \rangle \\ &\text{for all } \eta_p \in \text{Nor}^{k-1} M_p. \end{aligned}$$

Consequently, $\mathbb{T}^{k-1}(\nabla'_{X_p} \xi)$ depends only on X_p and ξ_p .

PROOF. If η is a section of $\text{Nor}^{k-1} M$ extending η_p , then $\langle \xi, \eta \rangle = 0$, so

$$\begin{aligned} 0 &= X_p(\langle \xi, \eta \rangle) = \langle \nabla'_{X_p} \xi, \eta_p \rangle + \langle \xi(p), \nabla'_{X_p} \eta \rangle \\ &= \langle \nabla'_{X_p} \xi, \eta_p \rangle + \langle \xi(p), \mathbb{T}^k \nabla'_{X_p} \eta \rangle, \end{aligned}$$

since $\xi(p) \in \text{Nor}^k M_p$, by assumption. Now apply (**). ♦

For any vector $\xi_p \in \text{Nor}^k M_p$ we can now let

$$A_{\xi_p}^k(X_p) = -\mathbb{T}^{k-1}(\nabla'_{X_p} \xi),$$

for any section ξ of $\text{Nor}^k M$ extending ξ_p , so that we have a map

$$A_{\xi_p}^k : M_p \rightarrow \text{Nor}^{k-1} M_p$$

satisfying

$$\langle A_{\xi_p}^k(X_p), \eta_p \rangle = \langle \xi_p, s^{k-1}(X_p, \eta_p) \rangle.$$

(Note that for $k = 0$ we are dealing with the 0 map.) For convenience, we will sometimes write

$$A^k(\xi_p; X_p) \quad \text{for} \quad A_{\xi_p}^k(X_p).$$

Finally, for the expression $\mathsf{T}^k(\nabla'_{X_p}\xi)$ we introduce a new symbol,

$$D_{X_p}^k \xi = \mathsf{T}^k(\nabla'_{X_p}\xi), \quad \xi \text{ a section of } \text{Nor}^k M.$$

It is easy to check that D^k is a connection on $\text{Nor}^k M$ which is compatible with the metric $\langle \cdot, \cdot \rangle$ on $\text{Nor}^k M$. We can now write our decomposition of $\nabla'_{X_p}\xi$ as

The Frenet Equations:

$$\begin{aligned} \nabla'_{X_p}\xi &= -A_{\xi_p}^k(X_p) + D_{X_p}^k \xi + s^k(X_p, \xi_p), \\ \text{for } \xi &\text{ a section of } \text{Nor}^k M \text{ and } X_p \in M_p. \end{aligned}$$

The terms $A_{\xi_p}^k(X_p)$ and $s^k(X_p, \xi_p)$ are completely determined by the maps s^{k-1} , s^k , and s^{k+1} . These Frenet equations essentially contain the Frenet equations for a curve when M is 1-dimensional; in general, they contain the Gauss equations (for $k = 0$) and (part of) the Weingarten equations for $k = 1$.

71. THEOREM. Let $M^n, \bar{M}^n \subset N^m$ be connected nicely curved submanifolds of a complete simply-connected manifold N of constant curvature. Let $\phi: M \rightarrow \bar{M}$ be an isometry. Suppose that for all $k \geq 1$ there are bundle isomorphisms $\tilde{\phi}^k: \text{Nor}^k M \rightarrow \text{Nor}^k \bar{M}$ covering ϕ which preserve inner products, second fundamental forms s^k , and connections D^k . Then there is an isometry A of N such that $\phi = A|_M$ and $\tilde{\phi}^k = A_*|_{\text{Nor}^k M}$.

PROOF. We obviously want to reduce this to Theorem 20. Notice first that since $\text{Osc}^t M_p = \text{Nor}^0 M_p \oplus \cdots \oplus \text{Nor}^{t-1} M_p$, and similarly for \bar{M} , the formal imbedding dimension $\#(M)$ must equal $\#(\bar{M})$. Taking into account Proposition 67, we see that there is no loss of generality in assuming that $\#(M) = \#(\bar{M}) = m$. Then the bundle isomorphisms $\tilde{\phi}^1, \dots, \tilde{\phi}^{l-1}$ combine to give a bundle isomorphism $\tilde{\phi}: \text{Nor} M \rightarrow \text{Nor} \bar{M}$. Clearly $\tilde{\phi}$ preserves inner products, second fundamental forms s^k , and connections D^k . In particular $\tilde{\phi}$ takes the second fundamental form $s (= s^1)$ to $\bar{s} (= \bar{s}^1)$. To prove that

$$(*) \quad \tilde{\phi}(D_X \xi) = \bar{D}_{\phi_* X}(\tilde{\phi}(\xi))$$

for all sections ξ of E , it suffices to consider separately sections ξ of $\text{Nor}^k M$. Then the Frenet equations give

$$D_X \xi = \perp(\nabla'_X \xi) = \begin{cases} D^1_X \xi + s^1(X, \xi) & k = 1 \\ -A^k_\xi(X) + D^k_X \xi + s^k(X, \xi) & k > 1, \end{cases}$$

with corresponding formulas for $\bar{D}_{\phi_* X} \tilde{\phi}(\xi)$. Since $\tilde{\phi}$ preserves D^k , as well as A^k and s^k (for they are determined by s^{k-1} , s^k and s^k), we see that equation (*) does indeed hold. ♦

Now we need certain equations satisfied by the connections D^k . We will state these in terms of vector fields on M and sections of $\text{Nor}^k M$. After the proof we will give another formulation, in terms of tangent vectors in M_p , and vectors in $\text{Nor}^k M_p$, which will make the result appear as a genuine generalization of the Codazzi-Mainardi equations for D .

72. THEOREM. Let $M \subset N$ be nicely curved. Then for all vector fields X, Y on M and sections ξ of $\text{Nor}^k M$ ($k \geq 0$) we have

The Generalized Codazzi-Mainardi Equations:

$$\begin{aligned} \mathsf{T}^{k+1} R'(X, Y)\xi &= [D^{k+1}_X(s^k(Y, \xi)) - s^k(\nabla_X Y, \xi) - s^k(Y, D^k_X \xi)] \\ &\quad - [D^{k+1}_Y(s^k(X, \xi)) - s^k(\nabla_Y X, \xi) - s^k(X, D^k_Y \xi)]. \end{aligned}$$

When N has constant curvature, the left side is zero.

PROOF. By the Frenet equations we have

$$\nabla'_Y \xi = -A^k_\xi(Y) + D^k_Y \xi + s^k(Y, \xi).$$

Since $A^k_\xi(Y)$ is a section of $\text{Nor}^{k-1} M$, Lemma 69 implies that

$$\mathsf{T}^{k+1} \nabla'_X \nabla'_Y \xi = \mathsf{T}^{k+1} \nabla'_X D^k_Y \xi + \mathsf{T}^{k+1} \nabla'_X s^k(Y, \xi).$$

Using (***) on page 170, and the definition of D^{k+1} , we thus have

$$(1) \quad \mathsf{T}^{k+1} \nabla'_X \nabla'_Y \xi = s^k(X, D^k_Y \xi) + D^{k+1}_X(s^k(Y, \xi)),$$

$$(1') \quad \mathsf{T}^{k+1} \nabla'_Y \nabla'_X \xi = s^k(Y, D^k_X \xi) + D^{k+1}_Y(s^k(X, \xi)).$$

We also have, by (***),

$$\mathsf{T}^{k+1} \nabla'_{[X, Y]} \xi = s^k([X, Y], \xi),$$

and thus

$$(2) \quad \mathsf{T}^{k+1} \nabla'_{[X,Y]} \xi = \mathbf{s}^k(\nabla_X Y, \xi) - \mathbf{s}^k(\nabla_Y X, \xi).$$

Substituting (1), (1'), (2) into the formula $R'(X, Y)\xi = \nabla'_X \nabla'_Y \xi - \nabla'_Y \nabla'_X \xi - \nabla'_{[X,Y]} \xi$, we obtain the desired result.

When N has constant curvature K_0 we have

$$R'(X, Y)\xi = K_0[\langle Y, \xi \rangle X - \langle X, \xi \rangle Y],$$

which is tangent to M . So $\mathsf{T}^{k+1} R'(X, Y)\xi = 0$. \blacklozenge

It is easily checked that in these generalized Codazzi-Mainardi equations, each of the expressions in brackets is linear in X , Y , and ξ over the C^∞ functions, and thus its value at p depends only on X_p, Y_p, ξ_p . To give this value explicitly, we note that we can consider \mathbf{s}^k as a section of the bundle $\text{Hom}(TM \times \text{Nor}^k M, \text{Nor}^{k+1} M)$. Using the connections ∇ , D^k , and D^{k+1} on TM , $\text{Nor}^k M$, and $\text{Nor}^{k+1} M$, we can define a natural connection $\tilde{\nabla}$ on this bundle (compare page 37 for the case $k = 0$). It is easily seen that Theorem 72 can be written

$$\begin{aligned} \mathsf{T}^{k+1} R'(X_p, Y_p)\xi_p &= (\tilde{\nabla}_{X_p} \mathbf{s}^k)(Y_p, \xi_p) - (\tilde{\nabla}_{Y_p} \mathbf{s}^k)(X_p, \xi_p) \\ X_p, Y_p &\in M_p, \text{ and } \xi_p \in \text{Nor}^k M_p. \end{aligned}$$

Now we can state the proper form of Lemma 65.

73. LEMMA (FUNDAMENTAL LEMMA OF RIEMANNIAN SUBMANIFOLD THEORY). Let $M \subset N$ be nicely curved. Then the set of normal connections D^k in $\text{Nor}^k M$ is the unique set of connections δ^k on $\text{Nor}^k M$ such that

$$(0) \quad \delta^0 = \nabla,$$

$$(1) \quad \delta^k \text{ is compatible with the metric in } \text{Nor}^k M:$$

$$X(\langle \xi, \eta \rangle) = \langle \delta_X^k \xi, \eta \rangle + \langle \xi, \delta_X^k \eta \rangle \quad \text{for sections } \xi, \eta \text{ of } \text{Nor}^k M,$$

$$(2) \quad \text{The } \delta^k \text{ satisfy the Codazzi-Mainardi equations:}$$

$$\begin{aligned} \mathsf{T}^{k+1} R'(X, Y)\xi &= [\delta^{k+1}_X (\mathbf{s}^k(Y, \xi)) - \mathbf{s}^k(\nabla_X Y, \xi) - \mathbf{s}^k(Y, \delta_X^k \xi)] \\ &\quad - [\delta^{k+1}_Y (\mathbf{s}^k(X, \xi)) - \mathbf{s}^k(\nabla_Y X, \xi) - \mathbf{s}^k(X, \delta_Y^k \xi)]. \end{aligned}$$

PROOF. We will show that if $\delta^k = D^k$, then $\delta^{k+1} = D^{k+1}$. Since $\delta^0 = \nabla = D^0$, this will prove the result. We begin by considering the expression

$$\begin{aligned} & \langle \delta^{k+1}_X \mathbf{s}^k(Y_1, \xi), \mathbf{s}^k(Z_1, \eta) \rangle - \langle \delta^{k+1}_{Y_1} \mathbf{s}^k(X, \xi), \mathbf{s}^k(Z_1, \eta) \rangle \\ & - \langle \delta^{k+1}_{Y_1} \mathbf{s}^k(Z_1, \eta), \mathbf{s}^k(X, \xi) \rangle + \langle \delta^{k+1}_{Z_1} \mathbf{s}^k(Y_1, \eta), \mathbf{s}^k(X, \xi) \rangle \\ & + \langle \delta^{k+1}_{Z_1} \mathbf{s}^k(X, \xi), \mathbf{s}^k(Y_1, \eta) \rangle - \langle \delta^{k+1}_X \mathbf{s}^k(Z_1, \xi), \mathbf{s}^k(Y_1, \eta) \rangle, \end{aligned}$$

where ξ, η are sections of $\text{Nor}^k M$. As in the proof of Lemma 65, we are led to the conclusion that we can write

$$\langle \delta^{k+1}_X \mathbf{s}^k(Y_1, \xi), \mathbf{s}^k(Z_1, \eta) \rangle - \langle \delta^{k+1}_X \mathbf{s}^k(Z_1, \xi), \mathbf{s}^k(Y_1, \eta) \rangle = \dots,$$

where \dots can be expressed in terms of $X, Y_1, Z_1, \xi, \eta, \delta^k = D^k$. In particular, if we choose $\xi = s^k(Y_2, \dots, Y_{k+2})$ and $\eta = s^k(Z_2, \dots, Z_{k+2})$, then we obtain

$$\begin{aligned} (3) \quad & \langle \delta^{k+1}_X s^{k+1}(Y_1, \dots, Y_{k+2}), s^{k+1}(Z_1, \dots, Z_{k+2}) \rangle \\ & - \langle \delta^{k+1}_X s^{k+1}(Z_1, Y_2, \dots, Y_{k+2}), s^{k+1}(Y_1, Z_2, \dots, Z_{k+2}) \rangle = \dots \end{aligned}$$

We will abbreviate the left side of this equation by

$$\{Y_1, \dots, Y_{k+2}; Z_1, \dots, Z_{k+2}\} - \{Z_1, Y_2, \dots, Y_{k+2}; Y_1, Z_2, \dots, Z_{k+2}\}.$$

Now consider the following expressions (the pattern becomes apparent by looking at the terms after the $-$ signs):

$$\begin{aligned} & \{Y_1, Y_2, Y_3, \dots, Y_{k+2}; Z_1, Z_2, Z_3, \dots, Z_{k+2}\} \\ & \quad - \{Z_1, Y_2, Y_3, \dots, Y_{k+2}; Y_1, Z_2, Z_3, \dots, Z_{k+2}\} \\ & \{Y_2, Z_1, Y_3, \dots, Y_{k+2}; Z_2, Y_1, Z_3, \dots, Z_{k+2}\} \\ & \quad - \{Z_2, Z_1, Y_3, \dots, Y_{k+2}; Y_2, Y_1, Z_3, \dots, Z_{k+2}\} \\ & \{Y_3, Z_2, Z_1, \dots, Y_{k+2}; Z_3, Y_2, Y_1, \dots, Z_{k+2}\} \\ & \quad - \{Z_3, Z_2, Z_1, \dots, Y_{k+2}; Y_3, Y_2, Y_1, \dots, Z_{k+2}\} \\ & \quad \vdots \\ & \{Y_{k+1}, Z_k, \dots, Z_1, Y_{k+2}; Z_{k+1}, Y_k, \dots, Y_1, Z_{k+2}\} \\ & \quad - \{Z_{k+1}, \dots, Z_1, Y_{k+2}; Y_{k+1}, \dots, Y_1, Z_{k+2}\} \\ & \{Y_{k+2}, Z_{k+1}, \dots, Z_1; Z_{k+2}, Y_{k+1}, \dots, Y_1\} \\ & \quad - \{Z_{k+2}, \dots, Z_1; Y_{k+2}, \dots, Y_1\}. \end{aligned}$$

Notice that each term after a $-$ sign is the same as the term on the next line, since s^{k+1} is symmetric. So adding all the equations (3) having the above expressions on the left we obtain

$$(4) \quad \langle \delta^{k+1}_X s^{k+1}(Y_1, \dots, Y_{k+2}), s^{k+1}(Z_1, \dots, Z_{k+2}) \rangle \\ - \langle \delta^{k+1}_X s^{k+1}(Z_1, \dots, Z_{k+2}), s^{k+1}(Y_1, \dots, Y_{k+2}) \rangle = \dots$$

But by (1) we also have

$$(5) \quad \langle \delta^{k+1}_X s^{k+1}(Y_1, \dots, Y_{k+2}), s^{k+1}(Z_1, \dots, Z_{k+2}) \rangle \\ + \langle \delta^{k+1}_X s^{k+1}(Z_1, \dots, Z_{k+2}), s^{k+1}(Y_1, \dots, Y_{k+2}) \rangle = \dots$$

So by adding (4) and (5) we obtain

$$(*) \quad \langle \delta^{k+1}_X s^{k+1}(Y_1, \dots, Y_{k+2}), s^{k+1}(Z_1, \dots, Z_{k+2}) \rangle = \dots$$

Since $\text{Nor}^{k+1} M_p$ is spanned by image s^{k+1} , this proves, as in Lemma 65, that δ^{k+1} is uniquely determined. \blacklozenge

Now for a manifold $M \subset N$ we define tensors \mathcal{F}_k by

$$\mathcal{F}_k(X_1, \dots, X_{k+1}, Y_1, \dots, Y_{k+1}) = \langle s^k(X_1, \dots, X_{k+1}), s^k(Y_1, \dots, Y_{k+1}) \rangle.$$

If $X_1, \dots, X_n \in M_p$ is a basis, then we can form the $n^{k+1} \times n^{k+1}$ matrix

$$(\mathcal{F}_k(X_{i_1}, \dots, X_{i_{k+1}}, X_{j_1}, \dots, X_{j_{k+1}})).$$

It is easy to see that this matrix is positive semi-definite and that its rank is just the dimension of ${}^* \text{Nor}^k M_p$.

74. THEOREM. Let $M, \bar{M} \subset N$ be connected nicely curved submanifolds of a complete simply-connected manifold N of constant curvature. Let $\phi: M \rightarrow \bar{M}$ be an isometry such that

$$\phi^* \bar{\mathcal{F}}_k = \mathcal{F}_k \quad \text{for all } k.$$

Then ϕ is the restriction of an isometry of N .

* For those who know about tensor products of vector spaces this can be expressed more simply: We can regard s^k as a linear map $s^k: M_p \otimes \dots \otimes M_p \rightarrow \text{Nor}^k M_p$, so \mathcal{F}_k is a bilinear map $\mathcal{F}_k: (M_p \otimes \dots \otimes M_p) \times (M_p \otimes \dots \otimes M_p) \rightarrow \mathbb{R}$. The matrix considered above is the matrix of this bilinear map with respect to the basis $\{X_{i_1} \otimes \dots \otimes X_{i_{k+1}}\}$ of $M_p \otimes \dots \otimes M_p$.

PROOF. The preceding remarks show that the dimension $\text{Nor}^k M$ must equal the dimension of $\text{Nor}^k \bar{M}$. Since s^k is onto $\text{Nor}^k M$, the procedure used in the proof of Proposition 66 allows us to construct bundle isomorphisms $\tilde{\phi}^k: \text{Nor}^k M \rightarrow \text{Nor}^k \bar{M}$ which preserve inner products and second fundamental forms s^k . Again arguing as in Proposition 66, but using Lemma 73 in place of Lemma 65, we see that the $\tilde{\phi}^k$ also preserve the connections D^k . So we can apply Theorem 71. ♦

We would also like to discuss when a given set of tensors $\{\mathcal{F}_k\}$ on a manifold M come from an imbedding of M in a complete manifold N of constant curvature. The Codazzi-Mainardi equations represent only one set of integrability conditions, and we still have to consider the other components of $\nabla'_X \nabla'_Y \xi - \nabla'_Y \nabla'_X \xi - \nabla'_{[X,Y]} \xi$. If ξ is a section of $\text{Nor}^k M$, then the only components we have to consider are $\mathsf{T}^{k-2}, \dots, \mathsf{T}^{k+2}$, where T^{k+1} is already taken care of by the Codazzi-Mainardi equations.

First consider T^{k+2} . From the Frenet equations

$$\nabla'_Y \xi = -A_\xi^k(Y) + D_Y^k \xi + s^k(Y, \xi)$$

we obtain

$$\mathsf{T}^{k+2} \nabla'_X \nabla'_Y \xi = \mathsf{T}^{k+2} \nabla'_X s^k(Y, \xi) = s^{k+1}(X, s^k(Y, \xi)) \quad \text{by (***)}.$$

Also

$$\begin{aligned} \mathsf{T}^{k+2} \nabla'_Y \nabla'_X \xi &= s^{k+1}(Y, s^k(X, \xi)) \\ \mathsf{T}^{k+2} \nabla'_{[X,Y]} \xi &= 0. \end{aligned}$$

So we have

$$\mathsf{T}^{k+2} R'(X, Y) \xi = s^{k+1}(X, s^k(Y, \xi)) - s^{k+1}(Y, s^k(X, \xi)).$$

In a space of constant curvature, the left side is 0. On the other hand, the right hand side is clearly always 0, since s^{k+2} is symmetric. Thus we do not obtain any new condition for imbedding in a manifold of constant curvature by looking at T^{k+2} .

Next consider T^{k-2} . The Frenet equations give us [recall the alternative notation $A^k(\xi; X)$ for $A_\xi^k(X)$]

$$\begin{aligned} \mathsf{T}^{k-2} \nabla'_X \nabla'_Y \xi &= -\mathsf{T}^{k-2} \nabla'_X A_\xi^k(Y) = A^{k-1}(A_\xi^k(Y); X) \\ \mathsf{T}^{k-2} \nabla'_Y \nabla'_X \xi &= -\mathsf{T}^{k-2} \nabla'_Y A_\xi^k(X) = A^{k-1}(A_\xi^k(X); Y) \\ \mathsf{T}^{k-2} \nabla'_{[X,Y]} \xi &= 0. \end{aligned}$$

So we obtain

$$\mathbb{T}^{k-2} R'(X, Y)\xi = A^{k-1}(A_\xi^k(Y); X) - A^{k-1}(A_\xi^k(X); Y).$$

In a space of constant curvature the left side is 0 (this is clear for $k > 2$, since $R'(X, Y)\xi$ is tangent to M ; it is true even for $k = 2$, since $R'(X, Y)\xi = K_0[\langle Y, \xi \rangle X - \langle X, \xi \rangle Y]$, and $\langle X, \xi \rangle = \langle Y, \xi \rangle = 0$). On the other hand, for any section η of Nor^{k-2} we have

$$\begin{aligned} \langle A^{k-1}(A_\xi^k(Y); X), \eta \rangle &= \langle A_\xi^k(Y), \mathbf{s}^{k-1}(X, \eta) \rangle \\ &= \langle \xi, \mathbf{s}^k(Y, \mathbf{s}^{k-1}(X, \eta)) \rangle, \end{aligned}$$

so we see that the right side of our equation is always 0. So, once again, we obtain no new conditions for imbedding M in a manifold of constant curvature.

Now consider \mathbb{T}^{k-1} . We have

$$\begin{aligned} \mathbb{T}^{k-1} \nabla'_X \nabla'_Y \xi &= -\mathbb{T}^{k-1} \nabla'_X A_\xi^k(Y) + \mathbb{T}^{k-1} \nabla'_X D_Y^k \xi \\ &= -D_X^{k-1} A_\xi^k(Y) - A^k(D_Y^k \xi; X) \\ \mathbb{T}^{k-1} \nabla'_Y \nabla'_X \xi &= -D_Y^{k-1} A_\xi^k(X) - A^k(D_X^k \xi; Y) \\ \mathbb{T}^{k-1} \nabla'_{[X, Y]} \xi &= -A_\xi^k([X, Y]) = -A_\xi^k(\nabla_X Y) + A_\xi^k(\nabla_Y X). \end{aligned}$$

Thus we obtain

$$\begin{aligned} -\mathbb{T}^{k-1} R'(X, Y)\xi &= [D_X^{k-1} A_\xi^k(Y) - A^k(D_X^k \xi; Y) - A_\xi^k(\nabla_X Y)] \\ &\quad - [D_Y^{k-1} A_\xi^k(X) - A^k(D_Y^k \xi; X) - A_\xi^k(\nabla_Y X)]. \end{aligned}$$

Taking the inner product with a section η of $\text{Nor}^{k-1} M$, we obtain the equivalent equation

$$\begin{aligned} \text{(a)} \quad -\langle R'(X, Y)\xi, \eta \rangle &= [\langle D_X^{k-1} A_\xi^k(Y), \eta \rangle - \langle D_X^k \xi, \mathbf{s}^{k-1}(Y, \eta) \rangle \\ &\quad - \langle \xi, \mathbf{s}^{k-1}(\nabla_X Y, \eta) \rangle] \\ &\quad - [\langle D_Y^{k-1} A_\xi^k(X), \eta \rangle - \langle D_Y^k \xi, \mathbf{s}^{k-1}(X, \eta) \rangle \\ &\quad - \langle \xi, \mathbf{s}^{k-1}(\nabla_Y X, \eta) \rangle]. \end{aligned}$$

But we also have

$$\begin{aligned} \langle A_\xi^k(Y), \eta \rangle &= \langle \xi, \mathbf{s}^{k-1}(Y, \eta) \rangle \\ \implies X(\langle A_\xi^k(Y), \eta \rangle) &= X(\langle \xi, \mathbf{s}^{k-1}(Y, \eta) \rangle) \end{aligned}$$

$$\begin{aligned}
&\implies \langle D^{k-1}_X A^k_\xi(Y), \eta \rangle + \langle A^k_\xi(Y), D^{k-1}_X \eta \rangle \\
&\quad = \langle D^k_X \xi, s^{k-1}(Y, \eta) \rangle + \langle \xi, D^k_X s^{k-1}(Y, \eta) \rangle \\
&\implies \langle D^{k-1}_X A^k_\xi(Y), \eta \rangle - \langle D^k_X \xi, s^{k-1}(Y, \eta) \rangle \\
&\quad = \langle \xi, D^k_X s^{k-1}(Y, \eta) \rangle - \langle \xi, s^{k-1}(Y, D^{k-1}_X \eta) \rangle.
\end{aligned}$$

Therefore the right side of (a) can be written

$$\begin{aligned}
&[\langle \xi, D^k_X s^{k-1}(Y, \eta) \rangle - \langle \xi, s^{k-1}(Y, D^{k-1}_X \eta) \rangle - \langle \xi, s^{k-1}(\nabla_X Y, \eta) \rangle] \\
&\quad - [\langle \xi, D^{k-1}_Y s^{k-1}(X, \eta) \rangle - \langle \xi, s^{k-1}(X, D^{k-1}_Y \eta) \rangle - \langle \xi, s^{k-1}(\nabla_Y X, \eta) \rangle] \\
&= \langle R'(X, Y)\eta, \xi \rangle, \quad \text{by the Codazzi-Mainardi equations.}
\end{aligned}$$

So equation (a) follows from the Codazzi-Mainardi equations; we obtain no new conditions by looking at T^{k-1} .

Finally, we have to look at T^k . We have

$$\begin{aligned}
T^k \nabla'_X \nabla'_Y \xi &= -T^k \nabla'_X A^k_\xi(Y) + T^k \nabla'_X D^k_Y \xi + T^k \nabla'_X s^k(Y, \xi) \\
&= -s^{k-1}(X, A^k_\xi(Y)) + D^k_X D^k_Y \xi - A^{k+1}(s^k(Y, \xi); X) \\
T^k \nabla'_Y \nabla'_X \xi &= -s^{k-1}(Y, A^k_\xi(X)) + D^k_Y D^k_X \xi - A^{k+1}(s^k(X, \xi); Y) \\
T^k \nabla'_{[X, Y]} \xi &= D^k_{[X, Y]} \xi.
\end{aligned}$$

So we obtain

$$\begin{aligned}
(b) \quad T^k R'(X, Y)\xi &= D^k_X D^k_Y \xi - D^k_Y D^k_X \xi - D^k_{[X, Y]} \xi \\
&\quad + s^{k-1}(X, A^k_\xi(Y)) - s^{k-1}(Y, A^k_\xi(X)) \\
&\quad + A^{k+1}(s^k(X, \xi); Y) - A^{k+1}(s^k(Y, \xi); X).
\end{aligned}$$

When $k = 0$, the terms involving s^{k-1} do not appear. In this case, if we take $\xi = Z$ to be a section of $\text{Nor}^0 M = TM$ we obtain

$$\begin{aligned}
R'(X, Y)Z &= R(X, Y)Z + A^1(s(X, Z); Y) - A^1(s(Y, Z); X) \\
&\quad \Downarrow \\
\langle R'(X, Y)Z, W \rangle &= \langle R(X, Y)Z, W \rangle + \langle s(X, Z), s(Y, W) \rangle - \langle s(X, W), s(Y, Z) \rangle
\end{aligned}$$

i.e., Gauss' equation. But for $k > 0$ we obtain an unsavory hybrid between Gauss' equation and the Ricci equations. We can obtain a nicer looking set of

equations by considering the bundles $\text{Osc}^k M$. There is a projection $\mathbb{T}^{[k]}: N_p \rightarrow \text{Osc}^k M_p$, defined by means of the orthogonal complement of $\text{Osc}^k M_p$ in N_p , and we can thus define a connection $D^{[k]}$ on $\text{Osc}^k M$ by

$$D^{[k]}_X \xi = \mathbb{T}^{[k]} \nabla'_X \xi \quad \xi \text{ a section of } \text{Osc}^k M.$$

This connection has a curvature tensor $R^{[k]}$ defined by

$$R^{[k]}(X, Y)\xi = D^{[k]}_X D^{[k]}_Y \xi - D^{[k]}_Y D^{[k]}_X \xi - D^{[k]}_{[X, Y]}\xi.$$

75. PROPOSITION. Let $M \subset N$ be nicely curved. Then for all vectors $X, Y \in M_p$ and $\xi \in \text{Osc}^k M_p$ we have the

Generalized Gauss Equation:

$$\begin{aligned} \mathbb{T}^{[k]} R'(X, Y)\xi = \\ R^{[k]}(X, Y)\xi + A^k(\mathbf{s}^{k-1}(X, \mathbb{T}^{k-1}\xi); Y) - A^k(\mathbf{s}^{k-1}(Y, \mathbb{T}^{k-1}\xi); X). \end{aligned}$$

So for $\xi, \eta \in \text{Osc}^k M_p$ we have

$$\begin{aligned} \langle R'(X, Y)\xi, \eta \rangle = \langle R^{[k]}(X, Y)\xi, \eta \rangle + \langle \mathbf{s}^{k-1}(X, \mathbb{T}^{k-1}\xi), \mathbf{s}^{k-1}(Y, \mathbb{T}^{k-1}\eta) \rangle \\ - \langle \mathbf{s}^{k-1}(Y, \mathbb{T}^{k-1}\xi), \mathbf{s}^{k-1}(X, \mathbb{T}^{k-1}\eta) \rangle. \end{aligned}$$

PROOF. We have

$$\begin{aligned} \nabla'_Y \xi &= D^{[k]}_Y \xi + \mathbb{T}^k \nabla'_Y \xi \\ &= D^{[k]}_Y \xi + \mathbb{T}^k (\nabla'_Y \mathbb{T}^{k-1} \xi) \\ &= D^{[k]}_Y \xi + \mathbf{s}^{k-1}(Y, \mathbb{T}^{k-1} \xi). \end{aligned}$$

Therefore

$$\begin{aligned} \nabla'_X \nabla'_Y \xi &= D^{[k]}_X D^{[k]}_Y \xi + \mathbf{s}^{k-1}(X, \mathbb{T}^{k-1} \cdot D^{[k]}_Y \xi) \\ &\quad + D^{[k]}_X \mathbf{s}^{k-1}(Y, \mathbb{T}^{k-1} \xi) + 0. \end{aligned}$$

So

$$\begin{aligned} (1) \quad \mathbb{T}^{[k]} \nabla'_X \nabla'_Y \xi &= D^{[k]}_X D^{[k]}_Y \xi + D^{[k]}_X \mathbf{s}^{k-1}(Y, \mathbb{T}^{k-1} \xi) \\ &= D^{[k]}_X D^{[k]}_Y \xi + \mathbb{T}^{k-1} \nabla'_X \mathbf{s}^{k-1}(Y, \mathbb{T}^{k-1} \xi) \\ &= D^{[k]}_X D^{[k]}_Y \xi - A^k(\mathbf{s}^{k-1}(Y, \mathbf{s}^{k-1} \xi); X). \end{aligned}$$

Also

$$(2) \quad \mathbb{T}^{[k]} \nabla'_Y \nabla'_X \xi = D^{[k]}_Y D^{[k]}_X \xi - A^k(\mathbf{s}^{k-1}(X, \mathbb{T}^{k-1} \xi); Y)$$

$$(3) \quad \mathbb{T}^{[k]} \nabla'_{[X, Y]} \xi = D^{[k]}_{[X, Y]} \xi.$$

Equations (1)–(3) give the result. ♦

Although we derived Gauss' equation from scratch, it is important to note that it is formally equivalent to equation (b) on page 179, in the following sense. For a section ξ of $\text{Osc}^k M$ we could define $D^{[k]}_X \xi$ as

$$\begin{aligned} D^{[k]}_X \xi = & [D^0_X \mathbb{T}^0 \xi + s^0(X, \mathbb{T}^0 \xi)] \\ & + [-A^1(\mathbb{T}^1 \xi; X) + D^1_X \mathbb{T}^1 \xi + s^1(X, \xi)] \\ & \vdots \\ & + [-A^{k-2}(\mathbb{T}^{k-2} \xi; X) + D^{k-2}_X \mathbb{T}^{k-2} \xi + s^{k-2}(X, \xi)] \\ & + [-A^{k-1}(\mathbb{T}^{k-1} \xi; X) + D^{k-1}_X \mathbb{T}^{k-1} \xi]. \end{aligned}$$

Then the equations of Proposition 75, together with the Codazzi-Mainardi equations, imply equations (b) on page 179; the verification of this claim is left to the reader. So the Codazzi-Mainardi equations and Gauss' equation are the full set of integrability conditions for the Frenet equations. But we still have a lot of work to do before we can decide when a set of tensors $\{\mathcal{F}_k\}$ on M come from an imbedding of M in a space of constant curvature.

First we claim that if ℓ has its usual significance, then

$$\begin{aligned} R^{[\ell]}(X, Y)\xi &= \mathbb{T}^{[\ell]} R'(X, Y)\xi \\ &= 0, \text{ when } N \text{ has constant curvature.} \end{aligned}$$

This follows immediately from Proposition 67, which shows that $D^{[\ell]} = \nabla'$ on Osc^ℓ . We could also note that $R^{[\ell]} = R^{[\ell+1]}$, and that the terms $A^{\ell+1}$ which then arise in Gauss' equation are 0, since they lie in $\text{Nor}^\ell M_p$.

Now we have to establish certain important identities for the curvature tensors $R^{[k]}$, analogous to those for $R = R^{[1]}$. Recall that we have

- (1) $R(X, Y)Z + R(Y, X)Z = 0$
- (2) $\langle R(X, Y)Z, W \rangle + \langle R(X, Y)W, Z \rangle = 0$
- (3) $\mathfrak{S}\{R(X, Y)Z\} = R(X, Y)Z + R(Y, Z)X + R(Z, X)Y = 0$
- (4) $\langle R(X, Y)Z, W \rangle + \langle R(Z, W)X, Y \rangle = 0.$

When we are dealing with a submanifold M of another Riemannian manifold N , these identities follow immediately from Gauss' equation

$$\langle R'(X, Y)Z, W \rangle = \langle R(X, Y)Z, W \rangle + \langle s(X, Z), s(Y, W) \rangle - \langle s(Y, Z), s(X, W) \rangle,$$

and the corresponding identities for R' . Similarly, we have

76. PROPOSITION. Let $M \subset N$ be nicely curved. Then

$$(1) \quad R^{[k]}(X, Y)\xi + R^{[k]}(Y, X)\xi = 0$$

$$(2) \quad \langle R^{[k]}(X, Y)\xi, \eta \rangle + \langle R^{[k]}(X, Y)\eta, \xi \rangle = 0$$

$$(3) \quad \mathfrak{S}\{R^{[k]}(X, Y) \cdot s^{k-2}(Z, \zeta)\} = 0 \quad \zeta \in \text{Nor}^{k-2} M_p$$

$$(3') \quad \mathfrak{S}'\{\langle R^{[k]}(X, Y) \cdot s^{k-1}(Z_1, \dots, Z_k), s^{k-1}(W_1, \dots, W_k) \rangle\} = 0$$

where \mathfrak{S}' indicates a cyclic sum over $(Y, Z_1, \dots, Z_k, W_1, \dots, W_k)$

$$(4) \quad 0 = \langle R^{[k]}(X_1, Y_1) \cdot s^{k-1}(X_2, \dots, X_{k+1}), s^{k-1}(Y_2, \dots, Y_{k+1}) \rangle \\ + \langle R^{[k]}(X_2, Y_2) \cdot s^{k-1}(Y_1, X_3, \dots, X_{k+1}), s^{k-1}(X_1, Y_3, \dots, Y_{k+1}) \rangle \\ + \langle R^{[k]}(X_3, Y_3) \cdot s^{k-1}(Y_1, Y_2, X_4, \dots, X_{k+1}), s^{k-1}(X_1, X_2, Y_4, \dots, Y_{k+1}) \rangle \\ \vdots \\ + \langle R^{[k]}(X_{k+1}, Y_{k+1}) \cdot s^{k-1}(Y_1, \dots, Y_k), s^{k-1}(X_1, \dots, X_k) \rangle.$$

Moreover, these identities follow formally from Gauss' equation for $R^{[k]}$ (and the properties of the curvature tensor R' for the ambient manifold).

PROOF. An easy computation. ♦

More important for us will be the (second) Bianchi identity

$$\mathfrak{S}\{(\nabla_Z R)(X, Y, W)\} = 0$$

[where we write R as $(X, Y, W) \mapsto R(X, Y, W)$].

Although we have derived this identity for the curvature tensor of a (symmetric) connection on the tangent bundle, it is actually more general:

77. PROPOSITION. Let ∇ be a connection on TM , with torsion tensor T , and let D be a connection on a bundle $\varpi: E \rightarrow M$ with curvature tensor $R = R_D$. Let $\tilde{\nabla}$ be the natural connection on the bundle $\text{Hom}(TM \times TM \times E, E)$ determined by the connections ∇ on TM and D on E . Then

$$\mathfrak{S}\{(\tilde{\nabla}_Z R)(X, Y, \xi)\} + \mathfrak{S}\{R(T(X, Y), Z)\xi\} = 0.$$

In particular, if $T = 0$, then

$$\mathfrak{S}\{(\tilde{\nabla}_Z R)(X, Y, \xi)\}.$$

PROOF. Exactly the same as the proof on pp. II.244–245, replacing W by ξ throughout. ♦

Note that when E is TM , the connection $\tilde{\nabla}$ is just denoted by ∇ , in conformity with previous usage.

78. COROLLARY. Let $M \subset N$ be nicely curved, and let $\tilde{\nabla}$ be the natural connection on $\text{Hom}(TM \times TM \times \text{Osc}^k M, \text{Osc}^k M)$ determined by the connections ∇ on TM and $D^{[k]}$ on $\text{Osc}^k M$. Then

$$(1) \quad \mathfrak{S}\{(\tilde{\nabla}_Z R^{[k]})(X, Y, \xi)\} = 0.$$

In addition,

$$(2) \quad \mathfrak{S}''\{(\tilde{\nabla}_{X_1} R^{[k]})(X, Y_1, s^{k-1}(X_2, \dots, X_{k+1}), s^{k-1}(Y_2, \dots, Y_{k+1}))\} = 0$$

where \mathfrak{S}'' indicates a cyclic sum over $(X_1, \dots, X_{k+1}, Y_1, \dots, Y_{k+1})$.

Moreover, equation (2) follows formally from (1), Gauss' equation for $R^{[k]}$, and the fact that the connection $D^{[k]}$ on $\text{Osc}^k M$ is compatible with the metric (and the properties of the curvature tensor R' for the ambient manifold).

PROOF. To obtain equation (2), we apply X to both sides of equation (4) in Proposition 76. We have, for example,

$$\begin{aligned} & X(\langle R^{[k]}(X_1, Y_1, s^{k-1}(X_2, \dots, X_{k+1})), s^{k-1}(Y_2, \dots, Y_{k+1}) \rangle) \\ &= \langle D^{[k]}_X(R^{[k]}(X_1, Y_1, s^{k-1}(X_2, \dots, X_{k+1}))), s^{k-1}(Y_2, \dots, Y_{k+1}) \rangle \\ &\quad + \langle R^{[k]}(X_1, Y_1, s^{k-1}(X_2, \dots, X_{k+1})), D^{[k]}_X s^{k-1}(Y_2, \dots, Y_{k+1}) \rangle, \end{aligned}$$

which by Corollary II.6.5 is

$$\begin{aligned} &= \langle (\tilde{\nabla}_X R^{[k]})(X_1, Y_1, s^{k-1}(X_2, \dots, X_{k+1})), s^{k-1}(Y_2, \dots, Y_{k+1}) \rangle \\ &\quad + \langle R^{[k]}(\nabla_X X_1, Y_1, s^{k-1}(X_2, \dots, X_{k+1})), s^{k-1}(Y_2, \dots, Y_{k+1}) \rangle \\ &\quad + \langle R^{[k]}(X_1, \nabla_X Y_1, s^{k-1}(X_2, \dots, X_{k+1})), s^{k-1}(Y_2, \dots, Y_{k+1}) \rangle \\ &\quad + \langle R^{[k]}(X_1, Y_1, D^{[k]}_X s^{k-1}(X_2, \dots, X_{k+1})), s^{k-1}(Y_2, \dots, Y_{k+1}) \rangle \\ &\quad + \langle R^{[k]}(X_1, Y_1, s^{k-1}(X_2, \dots, X_{k+1})), D^{[k]}_X s^{k-1}(Y_2, \dots, Y_{k+1}) \rangle. \end{aligned}$$

Using (1) we can replace the term involving $(\tilde{\nabla}_X R^{[k]})$ by two terms, involving $\tilde{\nabla}_{X_1} R^{[k]}$ and $\tilde{\nabla}_{Y_1} R^{[k]}$. After performing this substitution, and summing all the terms thus arising from equation (4) of Proposition 76, everything cancels out except for the terms which constitute equation (2). ♦

Corollary 78 will play an especially important role in our theory. To begin with, consider the case $R = R^{[1]}$, which depends only on the connection ∇ on TM . In the Remark after Lemma 65, we pointed out that for any bundle $\varpi: E \rightarrow M$ with a metric $\langle \cdot, \cdot \rangle$ and a symmetric section s of $\text{Hom}(TM \times TM, E)$, we can consider the ‘‘Codazzi-Mainardi equations’’ for a connection δ on E . The proof of Lemma 65 shows that if δ is to be compatible with the metric $\langle \cdot, \cdot \rangle$ and also satisfy this equation, then $\langle \delta_X s(Y_1, Y_2), s(Z_1, Z_2) \rangle$ is completely determined, by equation (*) in the proof. However, if we are given a δ which does satisfy (*), it is by no means clear that δ is compatible with the metric and satisfies the Codazzi-Mainardi equations. To see what is happening here, we need to examine the formulas much more closely. Returning to the proof of Lemma 65 one can see that when explicitly written out, equation (3) in the proof reads

$$\begin{aligned}
& \langle \delta_X s(Y_1, Y_2), s(Z_1, Z_2) \rangle - \langle \delta_X s(Z_1, Y_2), s(Y_1, Z_2) \rangle \\
&= \langle s(\nabla_{Y_1} X, Y_2) - s(\nabla_X Y_1, Y_2) + s(X, \nabla_{Y_1} Y_2) - s(Y_1, \nabla_X Y_2), s(Z_1, Z_2) \rangle \\
&- \langle s(\nabla_{Z_1} Y_1, Y_2) - s(\nabla_{Y_1} Z_1, Y_2) + s(Y_1, \nabla_{Z_1} Z_2) - s(Z_1, \nabla_{Y_1} Z_2), s(X, Y_2) \rangle \\
&+ \langle s(\nabla_X Z_1, Y_2) - s(\nabla_{Z_1} X, Y_2) + s(Z_1, \nabla_X Y_2) - s(X, \nabla_{Z_1} Y_2), s(Y_1, Z_2) \rangle \\
&+ Y_1(\langle s(X, Y_2), s(Z_1, Z_2) \rangle) - Z_1(\langle s(X, Y_2), s(Y_1, Z_2) \rangle) \\
&= \mathcal{E}(X, Y_1, Y_2, Z_1, Z_2), \text{ say.}
\end{aligned}$$

Following the proof a little further along, we arrive at the explicit formula

$$\begin{aligned}
2\langle \delta_X s(Y_1, Y_2), s(Z_1, Z_2) \rangle &= \mathcal{E}(X, Y_1, Y_2, Z_1, Z_2) + \mathcal{E}(X, Y_2, Z_1, Z_2, Y_1) \\
&+ X(\langle s(Y_1, Y_2), s(Z_1, Z_2) \rangle).
\end{aligned}$$

Now we can form

$$\begin{aligned}
& 2\langle \delta_U s(V, X), s(Y, Z) \rangle - 2\langle \delta_V s(U, X), s(Y, Z) \rangle \\
&= \mathcal{E}(U, V, X, Y, Z) \\
&\quad + \mathcal{E}(U, X, Y, Z, V) \\
&\quad - \mathcal{E}(V, U, X, Y, Z) \\
&\quad - \mathcal{E}(V, X, Y, Z, U) \\
&\quad + U(\langle s(V, X), s(Y, Z) \rangle) - V(\langle s(U, X), s(Y, Z) \rangle) \\
&= V(\langle s(U, X), s(Y, Z) \rangle) - Y(\langle s(U, X), s(V, Z) \rangle) + \cdots \\
&\quad + X(\langle s(U, Y), s(V, Z) \rangle) - Z(\langle s(U, Y), s(X, V) \rangle) + \cdots \\
&\quad - U(\langle s(V, X), s(Y, Z) \rangle) - Y(\langle s(V, X), s(U, Z) \rangle) + \cdots \\
&\quad - X(\langle s(V, Y), s(U, Z) \rangle) + Z(\langle s(V, Y), s(X, U) \rangle) + \cdots \\
&\quad + U(\langle s(V, X), s(Y, Z) \rangle) - V(\langle s(U, X), s(Y, Z) \rangle)
\end{aligned}$$

$$\begin{aligned}
&= \mathfrak{Z}\{Z(\langle s(X, U), s(V, Y) \rangle - \langle s(X, V), s(Y, U) \rangle)\} + \cdots \\
&\quad \text{where } \mathfrak{Z} \text{ indicates a cyclic sum over } (X, Y, Z) \\
&= \mathfrak{Z}\{Z(\langle R(X, Y)V, U \rangle)\} + \cdots \\
&= \mathfrak{Z}\{\langle \nabla_Z(R(X, Y)V), U \rangle\} + \cdots \\
&= \mathfrak{Z}\{\langle (\nabla_Z R)(X, Y, V), U \rangle\} + \cdots .
\end{aligned}$$

We have not troubled ourselves to write down all the \cdots terms, but, as you may suspect, when we apply Corollary 76(2) [for $k = 1$] we find that this equation comes down to precisely the Codazzi-Mainardi equations! In deriving this, we use only Gauss' equation for R , and the fact that ∇ is compatible with the metric (and properties of R' for the ambient manifold).

Similarly, we may form

$$\begin{aligned}
&2\langle \delta_X s(X_1, X_2), s(Y_1, Y_2) \rangle + 2\langle s(X_1, X_2), \delta_X s(Y_1, Y_2) \rangle \\
&= \mathcal{E}(X, X_1, X_2, Y_1, Y_2) \\
&\quad + \mathcal{E}(X, X_2, Y_1, Y_2, X_1) \\
&\quad + \mathcal{E}(X, Y_1, Y_2, X_1, X_2) \\
&\quad + \mathcal{E}(X, Y_2, X_1, X_2, Y_1) \\
&\quad + 2X(\langle s(X_1, X_2), s(Y_1, Y_2) \rangle) \\
&= X_1(\langle s(X, X_2), s(Y_1, Y_2) \rangle) - Y_1(\langle s(X, X_2), s(X_1, Y_2) \rangle) + \cdots \\
&\quad + X_2(\langle s(X, Y_1), s(Y_2, X_1) \rangle) - Y_2(\langle s(X, Y_1), s(X_2, X_1) \rangle) + \cdots \\
&\quad + Y_1(\langle s(X, Y_2), s(X_1, X_2) \rangle) - X_1(\langle s(X, Y_2), s(Y_1, X_2) \rangle) + \cdots \\
&\quad + Y_2(\langle s(X, X_1), s(X_2, Y_1) \rangle) - X_2(\langle s(X, X_1), s(Y_2, Y_1) \rangle) + \cdots \\
&\quad + 2X(\langle s(X_1, X_2), s(Y_1, Y_2) \rangle) \\
&= \mathfrak{Z}''\{X_1(\langle s(X, X_2), s(Y_1, Y_2) \rangle) - \langle s(X, Y_2), s(Y_1, X_2) \rangle\} + \cdots \\
&\quad \text{where } \mathfrak{Z}'' \text{ indicates a cyclic sum over } (X_1, X_2, Y_1, Y_2) \\
&= -\mathfrak{Z}''\{X_1(\langle R(X, Y_1)X_2, Y_2 \rangle)\} + \cdots \\
&= -\mathfrak{Z}''\{\langle \nabla_{X_1}(R(X, Y_1)X_2), Y_2 \rangle\} + \cdots \\
&= -\mathfrak{Z}''\{\langle (\nabla_{X_1} R)(X, Y_1, X_2), Y_2 \rangle\} + \cdots .
\end{aligned}$$

When we apply Corollary 78(2), it turns out that everything on the right side of this equation cancels, except the term $2X(\langle s(X_1, X_2), s(Y_1, Y_2) \rangle)$. So we see that δ is compatible with the metric!

More generally, we have

79. PROPOSITION. The fact that D^{k+1} satisfies the Codazzi-Mainardi equations and is compatible with the metric follows formally from equation (*) in

the proof of Lemma 73, Gauss' equation for $R^{[k+1]}$, and the fact that D^k is compatible with the metric (and the properties of R' for the ambient manifold).

PROOF. An abominable calculation. ♦

We are finally ready to consider the general imbedding question. The situation is rather complicated, and we will merely outline the results, without going into details. We are given a simply-connected manifold M^n and tensors $\mathcal{F}_0, \dots, \mathcal{F}_{\ell-1}$ on M , the tensor \mathcal{F}_k being covariant of order $2(k+1)$ and symmetric in the first $k+1$ arguments, in the last $k+1$ arguments, and under interchange of the first $k+1$ arguments with the last $k+1$ arguments. We assume that \mathcal{F}_0 is positive definite, and thus a Riemannian metric on M ; we will also denote \mathcal{F}_0 by $\langle \cdot, \cdot \rangle$. For $k \geq 1$ we assume that \mathcal{F}_k is positive semi-definite of constant rank $r_k > 0$. Set $m = n + r_1 + \dots + r_{\ell-1}$. We want to know when these tensors come from an immersion of M into a given complete m -dimensional manifold N of constant curvature K_0 . As usual, we can reduce this to a local problem, so we assume that M is diffeomorphic to \mathbb{R}^n , and we choose a basis X_1, \dots, X_n for the vector fields on M . For $1 \leq k \leq \ell - 1$ we take as our “ k^{th} normal bundle” $E^k = M \times \mathbb{R}^{r_k}$. Similarly, for our “ k^{th} osculating bundle” O^k we take the trivial bundle whose fibre over p is $O_p^k = M_p \oplus E_p^1 \oplus \dots \oplus E_p^{k-1}$. Each E^k has r_k natural sections $p \mapsto (p, (0, \dots, 0, 1, 0, \dots, 0))$, and we give E^k the Riemannian metric which makes these orthonormal; these metrics will all be denoted by $\langle \cdot, \cdot \rangle$. We now define $s^k: TM \times \dots \times TM \rightarrow E^k$ rather arbitrarily. By hypothesis, the $n^{k+1} \times n^{k+1}$ matrix

$$(\mathcal{F}_k(X_{i_1}, \dots, X_{i_{k+1}}, X_{j_1}, \dots, X_{j_{k+1}}))$$

has rank r_k at each point. Making M smaller if necessary, we can assume that there is a set \mathcal{S} of exactly r_k $(k+1)$ -tuples $(\alpha_1, \dots, \alpha_{k+1})$ such that the corresponding r_k rows of this matrix are everywhere linearly independent. Then for $(\alpha_1, \dots, \alpha_{k+1}) \in \mathcal{S}$ we define $s^k(X_{\alpha_1}, \dots, X_{\alpha_{k+1}})$ to be one of the r_k natural sections of E^k (choosing an arbitrary correspondence between the elements of \mathcal{S} and the r_k natural sections of E^k). There is now a unique way to define $s^k(X_{i_1}, \dots, X_{i_{k+1}})$ in general so that

$$\langle s^k(X_{i_1}, \dots, X_{i_{k+1}}), s^k(X_{j_1}, \dots, X_{j_{k+1}}) \rangle = \mathcal{F}_k(X_{i_1}, \dots, X_{i_{k+1}}, X_{j_1}, \dots, X_{j_{k+1}}).$$

Now we would like to define maps

$$s^k: TM \times E^k \rightarrow E^{k+1}$$

such that

$$s^k(X_i, s^k(X_{i_1}, \dots, X_{i_{k+1}})) = s^{k+1}(X_i, X_{i_1}, \dots, X_{i_{k+1}}).$$

But in this abstract set-up there is no way to prove that this map is well-defined. Instead we have to assume

(I) For each i and j , the $n^{k+1} \times 2n^{k+1}$ matrix

$$(\mathcal{F}_k(X_{i_1}, \dots, X_{i_{k+1}}, X_{j_1}, \dots, X_{j_{k+1}}), \mathcal{F}_{k+1}(X_i, X_{i_1}, \dots, X_{i_{k+1}}, X_j, X_{j_1}, \dots, X_{j_{k+1}}))$$

is of rank r_k . [The $(k+1)$ -tuple (i_1, \dots, i_{k+1}) determines a row of this matrix, and the $(k+1)$ -tuple (j_1, \dots, j_{k+1}) determines 2 different columns.]

With this assumption we can define s^k . We can thus also define the maps A_ξ^k for ξ an element of E^k .

Now we want to define connections D^k on the E^k . Consider first D^1 . The proof of Lemma 73 tells us that we have to define D^1 so that

$$(a_1) \quad \langle D^1_{X_i} s^1(X_{i_1}, X_{i_2}), s^1(X_{j_1}, X_{j_2}) \rangle = E_1(X_i, X_{i_1}, X_{i_2}, X_{j_1}, X_{j_2}),$$

where E_1 is some explicit expression we could work out. In order to know that we can define D^1 so that this formula holds, we must assume

(II₁) For each i, i_1, i_2 , the $n^2 \times 2n^2$ matrix

$$(\mathcal{F}_1(X_{h_1}, X_{h_2}, X_{j_1}, X_{j_2}), E_1(X_i, X_{i_1}, X_{i_2}, X_{j_1}, X_{j_2}))$$

is of rank r_2 . [The pair (h_1, h_2) determines a row, and the pair (j_1, j_2) determines 2 columns.]

With this assumption we can define D^1 so that equation (a₁) holds.

Of course, we already have the connection $D^0 = \nabla$ on TM determined by the metric $\mathcal{F}_0 = \langle \cdot, \cdot \rangle$, and we want to assume that its curvature tensor $R = R^{[1]}$ satisfies

$$\begin{aligned} \langle R'(X, Y)Z, W \rangle \\ = \langle R(X, Y)Z, W \rangle + \langle s^1(X, Z), s^1(Y, W) \rangle - \langle s^1(X, W), s^1(Y, Z) \rangle, \end{aligned}$$

i.e.,

$$\begin{aligned} (III_1) \quad K_0 \cdot [\langle X, W \rangle \cdot \langle Y, Z \rangle - \langle X, Z \rangle \cdot \langle Y, W \rangle] \\ = \langle R(X, Y)Z, W \rangle + \mathcal{F}_1(X, Z, Y, W) - \mathcal{F}_1(X, W, Y, Z). \end{aligned}$$

Proposition 79 then shows that D^1 satisfies the Codazzi-Mainardi equations and is compatible with the metric in E^1 . We can now define $D^{[2]}$ on O^2 by the formula on page 181, and it therefore makes sense to assume the generalized Gauss equation for $R^{[2]}$. Actually, it suffices to assume the special case

$$0 = \langle R^{[2]}(X, Y)s^1(X_1, X_2), s^1(Y_1, Y_2) \rangle \\ + \langle s^2(X, X_1, X_2), s^2(Y, Y_1, Y_2) \rangle - \langle s^2(Y, X_1, X_2), s^2(Y, Y_1, Y_2) \rangle,$$

i.e.,

$$(III_2) \quad 0 = \langle R^{[2]}(X, Y)s^1(X_1, X_2), s^1(Y_1, Y_2) \rangle \\ + \mathcal{F}_2(X, X_1, X_2, Y, Y_1, Y_2) - \mathcal{F}_2(Y, X_1, X_2, Y, Y_1, Y_2).$$

Now we want to define D^2 so that

$$(a_2) \quad \langle D^2_{X_i} s^2(X_{i_1}, X_{i_2}, X_{i_3}), s^2(X_{j_1}, X_{j_2}, X_{j_3}) \rangle \\ = E_2(X_i, X_{i_1}, X_{i_2}, X_{i_3}, X_{j_1}, X_{j_2}, X_{j_3}),$$

where E_2 is an explicit expression we could work out (it involves D^1 , but we already have an expression for D^1). In order to know that we can define D^2 so that this formula holds, we must assume

(II₂) For each i, i_1, i_2, i_3 , the $n^3 \times 2n^3$ matrix

$$(\mathcal{F}_2(X_{h_1}, X_{h_2}, X_{h_3}, X_{j_1}, X_{j_2}, X_{j_3}), E_2(X_i, X_{i_1}, X_{i_2}, X_{i_3}, X_{j_1}, X_{j_2}, X_{j_3}))$$

is of rank r_3 .

With this assumption we can define D^2 so that (a₂) holds. Then Proposition 79 shows that D^2 satisfies the Codazzi-Mainardi equations and is compatible with the metric in E^2 . We can now define $D^{[3]}$ on O^3 and it makes sense to assume the Gauss equation for $R^{[3]}$. Continuing in this way, we can formulate conditions

$$(II_k) \quad 1 \leq k \leq \ell - 1$$

$$(III_k) \quad 1 \leq k \leq \ell - 1$$

Finally, we can formulate

$$(IV) \quad R^{[\ell]} = 0.$$

Standard arguments about integrability conditions show that if the conditions (I), $\{(II_k)\}$, $\{(III_k)\}$, and (IV) hold, then the tensors $\mathcal{F}_0, \dots, \mathcal{F}_{\ell-1}$ on M come from an immersion of M into N .

PROBLEMS

1. Let $f: \mathbb{R}^n \rightarrow \mathbb{R}^n$ be a map with $\langle f(v), f(w) \rangle = \langle v, w \rangle$, where $\langle \cdot, \cdot \rangle$ is a non-degenerate inner product on \mathbb{R}^n . Show that

$$\langle f(\sum_i a_i e_i), f(e_j) \rangle = \langle \sum_i a_i f(e_i), f(e_j) \rangle$$

for all j , and conclude that f is linear.

2. Consider \mathbb{R}^{n+1} with the metric

$$-dx^0 \otimes dx^0 + dx^1 \otimes dx^1 + \cdots + dx^n \otimes dx^n.$$

(a) For the Levi-Civita connection (compare pg. II.342), the geodesics are the ordinary straight lines.

(b) If $g: \mathbb{R}^{n+1} \rightarrow \mathbb{R}^{n+1}$ is an isometry (with respect to this metric) with $g(0) = 0$ and $g_{*0} = \text{identity}$, then $g = \text{identity}$. [This can also be derived, as in Problem I-5, from an appropriate generalization of Corollary II.7-13.]

(c) If $f: \mathbb{R}^{n+1} \rightarrow \mathbb{R}^{n+1}$ is an isometry with $f(0) = 0$, then $f = f_{*0}$.

(d) Every isometry of \mathbb{R}^{n+1} is of the form $p \mapsto A(p) + q$ for $A \in O^1(n+1)$, and $q \in \mathbb{R}^{n+1}$.

3. Determine the geodesics of H^n by the same method used for S^n in Chapter I.9 (reflection through a 2-dimensional plane $P \subset \mathbb{R}^{n+1}$ is an isometry).

4. A **linear fractional transformation** is a map

$$z \mapsto \frac{az + b}{cz + d} \quad a, b, c, d \in \mathbb{C}, \quad ad - bc \neq 0,$$

of the extended complex plane $\mathbb{C} \cup \{\infty\}$ to itself.

(a) The set of all linear fractional transformations is a group under composition.

(b) For distinct z_1, z_2, z_3 , the transformation

$$z \mapsto \frac{z - z_2}{z - z_3} \bigg/ \frac{z_1 - z_2}{z_1 - z_3}$$

takes z_1 to 1, and z_2 to 0, and z_3 to ∞ .

(c) There is a linear fractional transformation taking any three distinct points $z_1, z_2, z_3 \in \mathbb{C} \cup \{\infty\}$ to any other three distinct points w_1, w_2, w_3 .

(d) If a linear fractional transformation keeps 1, 0, and ∞ fixed, then it is the identity.

(e) There is a unique linear fractional transformation taking z_1, z_2, z_3 to 1, 0, ∞ .

- (f) The transformation of part (c) is unique.
 (g) The linear fractional transformations which take the real axis to itself are precisely those with $a, b, c, d \in \mathbb{R}$.
 (h) The linear fractional transformations which take the upper half-plane onto itself are

$$f(z) = \frac{az + b}{cz + d},$$

$a, b, c, d \in \mathbb{R}$ and $ad - bc > 0$. We can then clearly assume that $ad - bc = 1$.

5. For distinct z_1, z_2, z_3 , the **cross ratio** (z, z_1, z_2, z_3) is defined as

$$(z, z_1, z_2, z_3) = \frac{z - z_2}{z - z_3} \bigg/ \frac{z_1 - z_2}{z_1 - z_3};$$

thus (z, z_1, z_2, z_3) is $f(z)$ where f is the linear fractional transformation taking z_1, z_2, z_3 to $1, 0, \infty$.

- (a) If g is a linear fractional transformation, then

$$(g(z), g(z_1), g(z_2), g(z_3)) = (z, z_1, z_2, z_3).$$

- (b) If $\theta = \arg w$ denotes an angle between the positive x -axis and the ray from 0 to w , so that $w = |w|e^{i\theta}$, then

$$\begin{aligned} \arg(z, z_1, z_2, z_3) &= \arg \frac{z - z_2}{z - z_3} - \arg \frac{z_1 - z_2}{z_1 - z_3} \\ &= \theta_1 - \theta_2 \quad \text{in the picture below.} \end{aligned}$$

Conclude that (z, z_1, z_2, z_3) is real if and only if z, z_1, z_2, z_3 lie on a circle or straight line.

- (c) A linear fractional transformation takes circles and straight lines into circles and straight lines.

6. In this problem we will use the notation on pages 319ff.

(a) The metric on the upper half-plane can be written

$$\langle \cdot, \cdot \rangle = \frac{dz \otimes d\bar{z}}{(\operatorname{Im} z)^2}.$$

(b) For the linear fractional transformation f of Problem 4(h), we have

$$\operatorname{Im} f(z) = \frac{\operatorname{Im} z}{|cz + d|^2}$$

$$f_z = \frac{\partial}{\partial z} \left(\frac{az + b}{cz + d} \right) = \frac{1}{(cz + d)^2}$$

$$f^*(dz) = df = f_z dz + f_{\bar{z}} d\bar{z} = \frac{dz}{(cz + d)^2}$$

$$f^*(d\bar{z}) = d\bar{f} = \frac{d\bar{z}}{(c\bar{z} + d)^2}.$$

(c) Conclude that f is an isometry of the upper half-plane.

(d) There is such an isometry taking any given point z to any other. *Hint:* Consider the linear fractional transformation taking z_1, z_2, z in the figure below to w_1, w_2, w .

(e) In the B^2 model, the linear fractional transformations keeping $S = \text{boundary } B^2$ fixed are isometries, and there are such isometries taking any point to any other. Conclude that these isometries are all the orientation preserving isometries of B^2 , by noting that rotations about the origin are linear fractional transformations.

(f) The geodesic circles around 0 in B^2 are clearly ordinary circles. Conclude that all geodesic circles are ordinary circles, and that the same result holds in the upper half-plane. (The converse can be proved exactly as in the higher dimensional case.)

7. (a) In the upper half-plane, the distance between $z_1 = x + iy_1$ and $z_2 = x + iy_2$ is

$$d(z_1, z_2) = \left| \int_{y_1}^{y_2} \frac{dy}{y} \right| = \left| \log \frac{y_2}{y_1} \right| = |\log(z_0, z_1, z_2, z_3)|$$

where $z_0 = x$ and $z_3 = \infty$.

(b) Let z_1, z_2 be any two points of the upper half-plane and let the semi-circle through z_1, z_2 perpendicular to the x -axis meet the x -axis at z_0 and z_3 . Then

$$d(z_1, z_2) = |\log(z_0, z_1, z_2, z_3)|.$$

(c) Similarly, find the formula for $d(z_1, z_2)$ in B^2 .

8. (a) The only geodesic maps $f: \mathbb{R}^n \rightarrow \mathbb{R}^n$ defined on all of \mathbb{R}^n are the affine maps. *Hint:* Assume $f(0) = 0$, and recall the parallelogram law for addition, as on pg. III.211.

(b) Every geodesic map from S^{n+} to S^{n+} is of the form $\phi^{-1} \circ A \circ \phi$, where $\phi: S^{n+} \rightarrow \mathbb{R}^n$ is the standard geodesic map, and $A: \mathbb{R}^n \rightarrow \mathbb{R}^n$ is affine.

9. In this Problem we will determine all geodesic maps $f: U \rightarrow V$ where U and V are open subsets of \mathbb{R}^n . We will use material from projective geometry—the reader is referred to Hartshorne [1] for all terms and theorems.* We need the fact that every $A = (a_{ij}) \in \text{GL}(n+1, \mathbb{R})$ determines a geodesic map $\bar{A}: \mathbb{P}^n \rightarrow \mathbb{P}^n$, and that every such map comes from some $A \in \text{GL}(n+1, \mathbb{R})$, unique up to multiplication by a real number. If we regard $\mathbb{R}^n \subset \mathbb{P}^n$, then the action of \bar{A} on \mathbb{R}^n is easily seen to be $\bar{A}(x^1, \dots, x^n) = (y^1, \dots, y^n)$, where

$$y^i = \frac{\sum_{j=1}^n a_{ij} x^j + a_{i,n+1}}{\sum_{j=1}^n a_{n+1,j} x^j + a_{n+1,n+1}}$$

(points where the denominator vanish go into the line at infinity). We will also use Desargue's Theorem and its converse (= its dual).

(a) Given any point $O \in \mathbb{R}^n$, and three lines l_1, l_2, l_3 through O which intersect U , show that there is a Desargue configuration with all other points in U . [*Hint:* In the figure at the top of the next page, points A, A' , and P are fixed, while B and B' , and C and C' , are chosen close together.] Conclude that the lines containing the $f(l_i \cap U)$ are concurrent. Thus show that there is a well-defined extension $\tilde{f}: \mathbb{P}^n \rightarrow \mathbb{P}^n$ with the property that if $P \in l_1 \cap l_2$ where l_1 and l_2 intersect U , then $\tilde{f}(P)$ is the intersection of the lines containing $f(l_1 \cap U)$ and $f(l_2 \cap U)$. Show also that \tilde{f} is one-one and onto.

(b) Let P, Q, R be three collinear points of \mathbb{P}^n . In the figure on the bottom of the next page, we first choose $A, A' \in U$, and then $B, B' \in U$, so that the lines

* For an analytic derivation see Scheffers [1; V.2. 429–432].

AA' and BB' intersect at a point $O \in U$. Show that we can also arrange for QA and RB to intersect at a point $C \in U$ and for RB' and QA' to intersect at a point $C' \in U$. Then show that AA' and BB' and CC' intersect at $O \in U$, so that we have a Desargue configuration with all points except P, Q, R in U . Conclude that $\tilde{f}(P)$, $\tilde{f}(Q)$, and $\tilde{f}(R)$ are collinear.

(c) Every geodesic map $f: U \rightarrow V$, where $U, V \in \mathbb{R}^n$ are open connected sets, is the restriction of some map \bar{A} for $A \in \text{GL}(n+1, \mathbb{R})$.

(d) Every geodesic map from H^n into H^n is of the form $\phi^{-1} \circ \bar{A} \circ \phi$, where $\phi: H^n \rightarrow B^n(1)$ is the standard geodesic map, and $\bar{A}: B^n(1) \rightarrow B^n(1)$ is a geodesic map which takes $B^n(1)$ into $B^n(1)$.

10. (a) Let $f: \mathbb{P}^2 \rightarrow \mathbb{P}^2$ be a geodesic map which takes a circle $\Sigma \subset \mathbb{R}^2 \subset \mathbb{P}^2$ into itself. Show that f is determined by knowing $f(P), f(Q), f(R)$ for distinct points $P, Q, R \in \Sigma$. *Hint:* Consider the tangent lines at P and Q , which intersect at some point S .

(b) Show that there is such an f for any given values of $f(P), f(Q), f(R)$. (You will need to use the fact that a conic is determined by 3 points and 2 tangents—see a book on projective geometry which treats conics.)

(c) Parts (a) and (b) show that the group of all geodesic maps $f: \mathbb{P}^2 \rightarrow \mathbb{P}^2$ with $f(\Sigma) = \Sigma$ has dimension 3. Using Problem 9, conclude that every geodesic map of H^2 onto itself is an isometry.

(d) Generalize to higher dimensions. Also consider the geodesic maps of S^n onto itself.

(e) Use the geodesic maps $H^n \rightarrow B^n(1)$ and $B^n(2) \rightarrow B^n(1)$ to describe an isometry between H^n and $B^n(2)$.

11. For vectors v_1, \dots, v_{m-1} in \mathbb{R}^m , we define $v_1 \times \dots \times v_{m-1}$ to be the unique vector with

$$\langle v_1 \times \dots \times v_{m-1}, w \rangle = \det \begin{pmatrix} v_1 \\ \vdots \\ v_{m-1} \\ w \end{pmatrix}$$

for all $w \in \mathbb{R}^m$.

(a) If $T: \mathbb{R}^m \rightarrow \mathbb{R}^m$ is an orientation preserving isometry, then

$$T(v_1 \times \dots \times v_{m-1}) = T(v_1) \times \dots \times T(v_{m-1}).$$

(b) Show how to define $v_1 \times \dots \times v_{m-1}$ for v_1, \dots, v_{m-1} in an oriented m -dimensional vector space V with an inner product $\langle \cdot, \cdot \rangle$.

12. (a) Let c be an arclength parameterized curve in $(N, \langle \cdot, \cdot \rangle)$, with $\kappa_1, \dots, \kappa_{m-1} = 0$, and Frenet frame $\mathbf{v}_1, \dots, \mathbf{v}_{m-1}$. Using $\nu_r = \mathbf{v}_r$ as a trivialization of the normal bundle of image c , show that

$$\begin{aligned} \Pi^r(\mathbf{v}_1, \mathbf{v}_1) &= \kappa_1 \delta_2^r \\ \beta_r^s(\mathbf{v}_1) &= -\kappa_{r-1} \delta_{r-1}^s + \kappa_r \delta_{r+1}^s. \end{aligned}$$

Hence Π^r and β_r^s are expressible in terms of $\kappa_1, \dots, \kappa_{m-1}$, and conversely, $\kappa_1, \dots, \kappa_{m-1}$ are expressible in terms of the Π^r and β_r^s .

(b) Derive Corollary 4 from Theorem 20.

(c) Prove the assertion on page 51 by showing that $\phi \circ c = c$ for every curve $c: [0, 1] \rightarrow M$ with $c(0) = p$.

13. Let $M^n, \bar{M}^n \subset S^m \subset \mathbb{R}^{m+1}$, with corresponding covariant differentiations $\nabla, \nabla', \nabla''$ and $\bar{\nabla}, \bar{\nabla}', \bar{\nabla}''$ (as in the proof of Theorem 27). Let $\phi: M \rightarrow \bar{M}$ be an isometry, and $\tilde{\phi}: \text{Nor } M \rightarrow \text{Nor } \bar{M}$ a bundle isomorphism covering ϕ between the normal bundles in S^m which preserves $\langle \cdot, \cdot \rangle$, s , and D . Let ν be the unit normal on S^m .

(a) The normal bundle $\text{Nor } M$ of M in \mathbb{R}^{m+1} has fibre $M_p^\perp = M_p^\perp \oplus \mathbb{R} \cdot \nu(p)$, and similarly for $\text{Nor } \bar{M}$. Define $\tilde{\phi}: \text{Nor } M \rightarrow \text{Nor } \bar{M}$ extending $\tilde{\phi}$ by $\tilde{\phi}(\nu(p)) = \nu(\phi(p))$. Then $\tilde{\phi}$ is inner product preserving.

(b) The second fundamental form \mathbf{s} of M in \mathbb{R}^{m+1} is given by

$$\mathbf{s}(X, Y) = s(X, Y) + \langle X, Y \rangle \nu,$$

and similarly for \bar{M} .

(c) The normal connection \mathbf{D} of $\text{Nor } M$ is given by

$$\mathbf{D}_X \xi = D_X \xi \quad \xi \text{ a section of } \text{Nor } M$$

$$\mathbf{D}_X \nu = 0,$$

and similarly for \bar{M} .

(d) The bundle isomorphism $\tilde{\phi}$ preserves \mathbf{s} and \mathbf{D} , so there is a Euclidean motion $A: \mathbb{R}^{m+1} \rightarrow \mathbb{R}^{m+1}$ with $\phi = A|_M$ and $\tilde{\phi} = A_*|_{\text{Nor } M}$.

(e) From the action of $\tilde{\phi}$ on $\nu(p)$ conclude that A keeps 0 fixed, so that it also represents an isometry of S^m .

(f) Treat the case of two manifolds $M^n, \bar{M}^n \subset H^m$ similarly.

14. Let $(M, \langle \cdot, \cdot \rangle)$ be as in part (2) of Theorem 19, except with Gauss' Equation as on page 55, with $K_0 = 1$. Let $\varpi: \mathbf{E} \rightarrow M$ be the bundle whose fibre at p is $\varpi^{-1}(p) \oplus \mathbb{R}$, and extend $\{ \cdot, \cdot \}$ to a metric $\{ \cdot, \cdot \}$ by

$$\{(v, a), (w, b)\} = \{v, w\} + ab.$$

Define a symmetric section σ of $\text{Hom}(TM \times TM, \mathbf{E})$ by

$$\sigma(X, Y) = (\sigma(X, Y), \langle X, Y \rangle),$$

and define a connection δ on \mathbf{E} compatible with $\{ \cdot, \cdot \}$ by

$$\begin{aligned} \delta_X \xi &= \delta_X \xi & \xi \text{ a section of } E \\ \delta_X \zeta &= 0 & \text{where } \zeta \text{ is the section} \\ & & \zeta(p) = (0, 1) \in \varpi^{-1}(p) \oplus \mathbb{R}. \end{aligned}$$

- (a) Gauss' equation, in the form with $K_0 = 0$, holds for σ .
- (b) The Codazzi-Mainardi equations hold for $\tilde{\nabla}\sigma$.
- (c) The Ricci equations hold for $R_\delta, \sigma, \mathbf{A}_\xi$.
- (d) Let $f: M \rightarrow \mathbb{R}^{m+1}$ be the isometric immersion given by Theorem 19, for $M, \mathbf{E}, \{ \cdot, \cdot \}, \sigma, \delta$. Regard f as an imbedding (by working locally), and let v be the vector field $\tilde{f}(\zeta)$ on $f(M)$. Then for all tangent vectors X, Y of $f(M)$ we have

$$\langle s(X, Y), v \rangle = \langle X, Y \rangle \implies \nabla'_X v = -X.$$

- (e) Let $p \in f(M)$ be a fixed point. Changing f by a translation, we can assume that $v(p) = -p$ (identifying tangent vectors of \mathbb{R}^{m+1} with elements of \mathbb{R}^{m+1} , as usual). Let $c: [0, 1] \rightarrow f(M)$ be a curve with $c(0) = p$. Then

$$\frac{dv(c(t))}{dt} = -c'(t),$$

and consequently $v(c(t)) = -c(t)$ for all t . Conclude that $f(M) \subset S^m$.

- (f) Treat the case $K_0 = -1$ similarly.

15. The Lie algebra $\mathfrak{gl}(m, \mathbb{R})$ has as a basis the matrices E_α^β which have zeros everywhere except for a 1 in *column* α and *row* β , so that

$$(E_\alpha^\beta)^\rho_\sigma = \delta_\alpha^\rho \delta_\sigma^\beta.$$

Let $\{\psi_\alpha^\beta\}$ be the dual basis, and let $\tilde{\psi}_\alpha^\beta$ be the left invariant 1-forms on $\text{GL}(m, \mathbb{R})$ which extend the ψ_α^β .

- (a) Show that

$$d\tilde{\psi}_\alpha^\beta = - \sum_{\gamma=1}^m \tilde{\psi}_\gamma^\beta \wedge \tilde{\psi}_\alpha^\gamma,$$

either by computing the brackets of the E_α^β and using the first equation on pg. I.396, or, more easily, by using the last equation on pg. I.404.

(b) The Lie algebra $\mathfrak{o}(m)$ has as a basis the matrices $E_\alpha^\beta - E_\beta^\alpha$, $\alpha < \beta$. The dual basis is

$$(l) \quad \phi_\alpha^\beta = \frac{\psi_\alpha^\beta - \psi_\beta^\alpha}{2}, \quad \alpha < \beta.$$

Define $\phi_\alpha^\beta = -\phi_\beta^\alpha$ for $\alpha > \beta$ and $\phi_\alpha^\alpha = 0$. Note that equation (l) still holds. Verify that we now have

$$d\tilde{\phi}_\alpha^\beta = -\sum_{\gamma=1}^m \tilde{\phi}_\gamma^\beta \wedge \tilde{\phi}_\alpha^\gamma.$$

(c) Derive Theorem 19 as a consequence of Theorems I.10-17 and I.10-18.

16. Use Problem I.7-14(a) to show that the even powers of λ in the characteristic polynomial $\chi(\lambda)$ of A can be expressed in terms of the determinants of the 2×2 submatrices of A .

17. For a hypersurface $M \subset \mathbb{R}^{n+1}$, generalize Proposition 2-6 so as to express the $(n+1)^{\text{st}}$ fundamental form in terms of the first n fundamental forms and the elementary symmetric curvatures.

18. For an immersion $f: M^n \rightarrow \mathbb{R}^{n+1}$ with normal map $N_f = \nu \circ f$, show that we still have

$$\text{III}_f = \text{I}_{N_f} = -\text{II}_{N_f}.$$

19. Let c be a curve in a hypersurface $M \subset N$ of a manifold of constant curvature K_0 , and let X be a vector field of N along M . Then $\nabla'_{c'(s)} X$ is always a multiple of $c'(s)$ if and only if the ruled surface $\{\exp_{c(s)} tX(c(s))\}$ has constant intrinsic curvature K_0 .

20. Let $\sigma: S^n - \{\text{north pole}\} \rightarrow \mathbb{R}^n$ be the version of stereographic projection in which S^n denotes the standard unit sphere around 0.

(a) For this σ we have

$$\sigma(p) = \left(\frac{p^1}{1 - p^{n+1}}, \dots, \frac{p^n}{1 - p^{n+1}} \right)$$

$$\sigma^{-1}(y) = \left(\frac{2y^1}{1 + \sum_i (y^i)^2}, \dots, \frac{2y^n}{1 + \sum_i (y^i)^2}, \frac{\sum_i (y^i)^2 - 1}{1 + \sum_i (y^i)^2} \right).$$

(b) Let $c: [0, 2\pi] \rightarrow \mathbb{R}^n$ be a curve, parameterized proportionally to arclength, which goes once around a circle centered at 0 and passing through y , so that c' has squared length $|y|^2$. Then $(\sigma^{-1} \circ c)'$ has squared length

$$\frac{4|y|^2}{[1 + |y|^2]^2}.$$

Thus σ^{-1}_* multiplies lengths of tangent vectors at y by $2/(1 + |y|^2)$.

21. Let $\sigma: S^2 \rightarrow \mathbb{C} \cup \{\infty\}$ be stereographic projection, where S^2 is the standard unit sphere around $(0, 0, 0)$.

(a) If R_θ is rotation of S^2 through an angle of θ around the z -axis, then $\sigma \circ R_\theta \circ \sigma^{-1}: \mathbb{C} \cup \{\infty\} \rightarrow \mathbb{C} \cup \{\infty\}$ is just $z \mapsto e^{i\theta}z$.

(b) If R'_θ is rotation through an angle of θ around the y -axis, calculate that $\sigma \circ R'_\theta \circ \sigma^{-1}$ is

$$z \mapsto \frac{(1 + \cos \theta)z - \sin \theta}{(\sin \theta)z + (1 + \cos \theta)}.$$

(c) The group $SO(3)$ is generated by all R_θ and R'_θ . (A direct proof can be given, or one can note that $SO(3)$ is 3-dimensional, and the R_θ and R'_θ do not commute.) The group of all 4×4 complex matrices $\begin{pmatrix} a & b \\ c & d \end{pmatrix}$ satisfying the conditions on page 109 is also 3-dimensional. Conclude that this group is precisely the group of all $\sigma \circ A \circ \sigma^{-1}$ for $A \in O(3)$.

22. Consider $B^2(2)$, with the metric on page 7. From pg. II.301 we see that the geodesic circle of radius r is given by

$$c(\theta) = 2 \tanh \frac{r}{2} (\cos \theta, \sin \theta) \quad 0 \leq \theta \leq 2\pi.$$

(a) Calculate that

$$|c'(\theta)| = \sinh r.$$

(b) Then verify the formula for I given on page 118.

23. (a) For a coordinate system u, v on a 2-dimensional Riemannian manifold, show that the formula on page 132 can be written

$$\Delta f = \frac{1}{W} \left\{ \frac{\partial}{\partial u} \left(\frac{G \frac{\partial f}{\partial u} - F \frac{\partial f}{\partial v}}{W} \right) + \frac{\partial}{\partial v} \left(\frac{E \frac{\partial f}{\partial v} - F \frac{\partial f}{\partial u}}{W} \right) \right\},$$

where $W = \sqrt{EG - F^2}$.

(b) If (u, v) is isothermal (this means that $E = G$ and $F = 0$; compare pg. II.297), then

$$\Delta f = \frac{1}{E} \left(\frac{\partial^2 f}{\partial u^2} + \frac{\partial^2 f}{\partial v^2} \right).$$

(c) A coordinate system (x, y) on a 2-dimensional Riemannian manifold is isothermal if and only if $\Delta_1 x = \Delta_1 y$ and $\Delta_1(x, y) = 0$.

(d) If (x, y) is an isothermal coordinate system, then $\Delta x = \Delta y = 0$.

(e) If $\Delta x = 0$, then there is locally a function y with

$$dy = \frac{F \frac{\partial x}{\partial u} - E \frac{\partial x}{\partial v}}{W} du + \frac{G \frac{\partial x}{\partial u} - F \frac{\partial x}{\partial v}}{W} dv$$

(here E, F, G are the components of $\langle \cdot, \cdot \rangle$ in the (u, v) coordinate system). The functions x and y satisfy $\Delta_1 x = \Delta_1 y$ and $\Delta_1(x, y) = 0$, so (x, y) is an isothermal coordinate system.

24. Let h be a function on a 2-dimensional Riemannian manifold such that the sets $h = \text{constant}$ give a foliation of the manifold.

(a) Suppose that there is an isothermal coordinate system (x, y) such that one family of parameter curves lie along the curves $h = \text{constant}$; thus $x = f \circ h$ for some function f . Use Problem 23 to show that

$$\Delta h \cdot (f' \circ h) + \Delta_1 h \cdot (f'' \circ h) = 0.$$

Hence $\Delta h / \Delta_1 h$ is some function composed with h .

(b) Conversely, if $\Delta h / \Delta_1 h = F \circ h$ for some function F , and we set $x = f \circ h$ for

$$f' = e^{-\int F},$$

then $\Delta x = 0$, and the function y of Problem 23(e) satisfies

$$\Delta_1 y = e^{-2 \int F} \Delta_1 h.$$

(c) So

$$\langle \cdot, \cdot \rangle = \frac{1}{\Delta_1 h} (dh \otimes dh + e^{2 \int F} dy \otimes dy).$$

(d) If we have equations (a) and (b) on page 155, then the corresponding metrics are

$$\begin{aligned} & \frac{1}{f \circ K} (dK \otimes dK + e^{2 \int g/f} dy \otimes dy) \\ & \frac{1}{f \circ \bar{K}} (d\bar{K} \otimes d\bar{K} + e^{2 \int g/f} d\bar{y} \otimes d\bar{y}). \end{aligned}$$

So there is a one-parameter family of isometries between the surfaces.

(e) There is a function x with

$$dx \otimes dx = \frac{1}{f \circ K} dK \otimes dK,$$

and similarly for \bar{x} . Hence, each surface is isometric to a surface of revolution (see formula (4) on pg. III.158).

25. Let V and W be two inner product spaces of the same dimension. Let $\{v_\rho\}$ be an indexed set of (not necessarily distinct) vectors which span V , and let $\{\bar{v}_\rho\}$ span W . Suppose that

$$\langle v_\rho, v_\sigma \rangle = \langle \bar{v}_\rho, \bar{v}_\sigma \rangle \quad \text{for all } \rho, \sigma.$$

Show that $\sum_\rho c_\rho v_\rho = 0 \implies \sum_\rho c_\rho \bar{v}_\rho = 0$, and conclude that there is a unique inner product preserving isomorphism $V \rightarrow W$ which takes v_ρ to \bar{v}_ρ .

CHAPTER 8

THE SECOND VARIATION

In this chapter we return to the study of the calculus of variations, and introduce an important (essentially classical) construction, which has surprisingly significant consequences for differential geometry. Recall that the calculus of variations was first invoked in order to find paths which locally minimize the length function L for a Riemannian manifold M . In the course of our investigations we found that the energy function was more convenient to work with, and that the critical paths for the length function are precisely the same as those for the energy function, except that the latter are necessarily parameterized proportionally to arclength. These critical points for E are, of course, the geodesics on M , and at present we know only that *sufficiently small* pieces of geodesics are paths of minimal length.

We now want to develop conditions which determine when a given geodesic is, in its entirety, a path of smaller length than nearby paths. We recall one fact from Problem I.9-31: For a piecewise C^∞ curve $\gamma: [a, b] \rightarrow M$ we always have

$$[L_a^b(\gamma)]^2 \leq (b - a)E_a^b(\gamma),$$

with equality precisely when γ is parameterized proportionally to arclength. From this it is easy to see that a geodesic γ has minimal *length* among all nearby paths between $\gamma(a)$ and $\gamma(b)$ precisely when it has minimal *energy* among all such paths. Thus we lose no information by restricting all our considerations to the energy function E .

We begin with a brief summary of the results which we already have. Consider a piecewise C^∞ path $\gamma: [a, b] \rightarrow M$ and a piecewise C^∞ variation $\alpha: (-\varepsilon, \varepsilon) \times [a, b] \rightarrow M$ of γ . We define

$$\begin{aligned} W(t) &= \frac{\partial \alpha}{\partial u}(0, t) && \text{the "variation vector field"} \\ V(t) &= \frac{d\gamma}{dt} && \text{the "velocity vector field of } \gamma\text{"} \\ A(t) &= \frac{D}{dt} V(t) && \text{the "acceleration vector field of } \gamma\text{",} \end{aligned}$$

and if $a = t_0 < \cdots < t_N = b$ includes all discontinuity points of V , we set

$$\begin{aligned}\Delta_{t_i} V &= V(t_i^+) - V(t_i^-) \quad i = 1, \dots, N-1 \\ \Delta_{t_0} V &= V(t_0^+) \\ \Delta_{t_N} V &= -V(t_N^-).\end{aligned}$$

We then have the following formula (Theorem II.6-14) for the “first variation” of E :

$$\left. \frac{dE(\bar{\alpha}(u))}{du} \right|_{u=0} = - \int_a^b \langle W(t), A(t) \rangle dt - \sum_{i=0}^N \langle W(t_i), \Delta_{t_i} V \rangle;$$

for variations keeping the endpoints fixed, the sum can be written from 1 to $N-1$. From this formula we found that γ is a geodesic ($A(t) = 0$) if and only if γ is a critical point for E .

Recall that if $f: M \rightarrow \mathbb{R}$ is a real-valued function, then $f_*: M_p \rightarrow \mathbb{R}_{f(p)}$ may be determined as follows. Given $X_p \in M_p$, we choose a path $c: (-\varepsilon, \varepsilon) \rightarrow M$ with $c'(0) = X_p$; then

$$f_*(X_p) = \text{tangent vector of } f \circ c \text{ at } 0 = \left. \frac{df(c(u))}{du} \right|_{u=0} \cdot \left. \frac{d}{dt} \right|_{f(p)}.$$

This suggests some notation which is exactly analogous, except that we will be sloppy and throw away the uninteresting d/dt term. For any piecewise C^∞ vector field W along γ , we define

$$E_*(W) = \left. \frac{dE(\bar{\alpha}(u))}{du} \right|_{u=0},$$

where α is some piecewise C^∞ variation of γ with W as its variation vector field. The first variation formula shows that the right side depends only on W , so that $E_*(W)$ is really well-defined; the formula also shows that E_* is linear. Perhaps we should explicitly make the observation that any piecewise C^∞ vector field W is the variation vector field of some α ; for example, we can take

$$\alpha(u, t) = \exp u \cdot W(t).$$

As this example shows, we can even arrange for α to be a variation keeping endpoints fixed if $W(a) = W(b) = 0$. The notation $E_*(W)$ suggests that piecewise C^∞ vector fields W along γ may be thought of as “tangent vectors” to the curve γ . Actually, it will be convenient to restrict this terminology to those W which vanish at a and b . So if Ω denotes the set of all piecewise C^∞ paths $\gamma: [a, b] \rightarrow M$ between two fixed points p and q , we will define Ω_γ , the “tangent space of Ω at γ ”, to be the vector space

$$\Omega_\gamma = \{W : W \text{ is a piecewise } C^\infty \text{ vector field along } \gamma \text{ with } W(a) = W(b) = 0\}.$$

We know that if $E: \Omega \rightarrow \mathbb{R}$ has a minimum, or even a local minimum, at γ , then γ must be a geodesic, so $E_*: \Omega_\gamma \rightarrow \mathbb{R}$ must be 0. This is a *necessary* condition, analogous to the *necessary* condition $D_i f(x) = 0$ for a function $f: \mathbb{R}^n \rightarrow \mathbb{R}$ to have a local maximum or minimum at $x \in \mathbb{R}^n$. We also want to find *sufficient* conditions for a geodesic γ to be a minimum for E ; as a guide, we will first recall what is known in the case of functions $f: \mathbb{R}^n \rightarrow \mathbb{R}$.

In the one variable case, there are very easy sufficient conditions for a function $f: \mathbb{R} \rightarrow \mathbb{R}$ to have a local maximum or minimum:

- (1) If $f'(x) = 0$ and $f''(x) > 0$, then f has a (strict) local minimum at x .
- (2) If $f'(x) = 0$ and $f''(x) < 0$, then f has a (strict) local maximum at x .

To prove (1), for example, we simply note that if $f'(x) = 0$ and $f''(x) > 0$, then we must have $f'(x+h) > 0$ for small $h > 0$, and $f'(x+h) < 0$ for small $h < 0$. So f is strictly decreasing in some interval $(x-\varepsilon, x]$, and strictly increasing on some interval $[x, x+\varepsilon)$. We also obtain, automatically, the following partial converses:

- (1') If f has a local minimum at x , and $f''(x)$ exists, then $f''(x) \geq 0$.
- (2') If f has a local maximum at x , and $f''(x)$ exists, then $f''(x) \leq 0$.

[Proof of (1'): If we had $f''(x) < 0$, then f would have a strict local maximum at x , by (2), contradicting the hypothesis that it has a local minimum at x .]

For functions $f: \mathbb{R}^2 \rightarrow \mathbb{R}$, the situation becomes more complicated. We certainly cannot expect to conclude that a critical point x of f is a local minimum simply because

$$D_{1,1}f(x) > 0 \quad \text{and} \quad D_{2,2}f(x) > 0;$$

this condition merely implies that x is a local minimum for f along the lines through x which are parallel to one of the axes. We would need the much

stronger condition (Problem 1) that every second order directional derivative of f is positive,

$$\left. \frac{d^2}{dt^2} \right|_{t=0} f(x + tv) > 0 \quad \text{all } v \in \mathbb{R}^2.$$

If we use *mixed* partial derivatives, then we have a simple sufficient condition that a critical point x be *either* a (strict) local maximum *or* a (strict) local minimum, namely

$$(I) \quad \det \left(\frac{\partial^2 f}{\partial x_i \partial x_j}(x) \right) > 0.$$

We have essentially already proved this in Chapter 2, for this inequality is exactly the condition that x be an elliptic point of the surface $\{(x_1, x_2, f(x_1, x_2))\}$, and therefore lie on one side of its tangent plane at x ; this tangent plane is just the (x_1, x_2) -plane, since x is a critical point. If condition (I) is satisfied, we can then distinguish between a local maximum and a local minimum merely by examining the sign of $\partial^2 f / \partial (x_1)^2$ at x . If, instead of condition (I), we have

$$(II) \quad \det \left(\frac{\partial^2 f}{\partial x_i \partial x_j}(x) \right) < 0,$$

then x definitely is *not* either a local maximum or minimum for f . This also follows from the considerations of Chapter 2, for in this case the surface $\{(x_1, x_2, f(x_1, x_2))\}$ lies on both sides of its tangent plane. When the determinant is 0, we are in the borderline case where no conclusions can be drawn. Essentially the same considerations hold for functions $f: \mathbb{R}^n \rightarrow \mathbb{R}$, except that it is no longer so easy to find out if the eigenvalues of

$$\left(\frac{\partial^2 f}{\partial x_i \partial x_j}(x) \right)$$

all have the same sign, which is precisely the condition that f have either a local maximum or a local minimum at x .

Notice that the analogues of (1') and (2') require no modification: If $f: \mathbb{R}^n \rightarrow \mathbb{R}$ has a local minimum at x , then surely

$$\left. \frac{d^2}{dt^2} \right|_{t=0} f(x + tv) \geq 0$$

for all $v \in \mathbb{R}^n$ for which this limit exists. In fact, if the opposite equality held for some $v \in \mathbb{R}^n$, then f would have a strict local maximum at x along the line $\{x + tv: t \in \mathbb{R}\}$.

Our aim now is to see what information we can get when we generalize these considerations of elementary calculus, and examine the second derivative $d^2E(\bar{\alpha}(u))/du^2(0)$, for all variations α of a geodesic $\gamma: [a, b] \rightarrow M$; classically, this second derivative was called the “second variation” of E . Our remarks about n -dimensional calculus might suggest that it would be even more useful to consider “mixed partial derivatives”, and even if they don’t suggest it, mixed partial derivatives do turn out to be the thing to look at. We first define a **2-parameter variation** α of γ to be a function

$$\alpha: U \times [a, b] \rightarrow M,$$

for some neighborhood U of $0 \in \mathbb{R}^2$, such that

- (1) $\alpha(0, t) = \gamma(t)$
- (2) there is a partition $a = t_0 < \cdots < t_N = b$ of $[a, b]$ so that α is C^∞ on each $U \times [t_{i-1}, t_i]$.

We say that α is a variation **keeping endpoints fixed** if

- (3) For all $u \in U$, we have

$$\begin{aligned}\alpha(u, a) &= \gamma(a) \\ \alpha(u, b) &= \gamma(b).\end{aligned}$$

As before, we let $\bar{\alpha}(u)$ be the path $t \mapsto \alpha(u, t)$. A 2-parameter variation α of γ gives rise to two “variation vector fields” W_1 and W_2 along γ , defined by

$$W_i(t) = \frac{\partial \alpha}{\partial u_i}(0, 0, t).$$

Notice that the W_i may be only piecewise C^∞ vector fields along γ even if γ itself is everywhere C^∞ .

1. THEOREM (SECOND VARIATION FORMULA). Let $\gamma: [a, b] \rightarrow M$ be a geodesic, with velocity vector field $V(t) = d\gamma/dt$, and let $\alpha: U \times [a, b] \rightarrow M$ be a 2-parameter variation of γ , with variation vector fields

$$W_i(t) = \frac{\partial \alpha}{\partial u_i}(0, 0, t).$$

Choose $a = t_0 < \cdots < t_N = b$ to include all discontinuity points of DW_1/dt , and let

$$\begin{aligned}\Delta_{t_i} \frac{DW_1}{dt} &= \frac{DW_1}{dt}(t_i^+) - \frac{DW_1}{dt}(t_i^-) \quad i = 1, \dots, N-1 \\ \Delta_{t_0} \frac{DW_1}{dt} &= \frac{DW_1}{dt}(t_0^+) \\ \Delta_{t_N} \frac{DW_1}{dt} &= -\frac{DW_1}{dt}(t_N^-).\end{aligned}$$

Then

$$\begin{aligned}\frac{\partial^2 E(\bar{\alpha}(u))}{\partial u_1 \partial u_2} \Big|_{(u_1, u_2) = (0, 0)} &= - \int_a^b \left\langle W_2(t), \frac{D^2 W_1}{dt^2} + R(W_1(t), V(t))V(t) \right\rangle dt \\ &\quad - \sum_{i=0}^N \left\langle W_2(t_i), \Delta_{t_i} \frac{DW_1}{dt} \right\rangle.\end{aligned}$$

(When α is a variation keeping endpoints fixed, the sum can be written from 1 to $N-1$.)

PROOF. By the first variation formula (Theorem II.6-14), we have

$$\frac{\partial E(\bar{\alpha}(u))}{\partial u_2} \Big|_{u_2=0} = - \int_a^b \left\langle \frac{\partial \alpha}{\partial u_2}, \frac{D}{dt} \frac{\partial \alpha}{\partial t} \right\rangle dt - \sum_{i=0}^N \left\langle \frac{\partial \alpha}{\partial u_2}, \Delta_{t_i} \frac{\partial \alpha}{\partial t} \right\rangle,$$

where all terms on the right side are to be evaluated at $(t, u_1, 0)$. So

$$\begin{aligned}(1) \quad \frac{\partial^2 E(\bar{\alpha}(u))}{\partial u_1 \partial u_2} \Big|_{u_2=0} &= - \int_a^b \left\langle \frac{D}{\partial u_1} \frac{\partial \alpha}{\partial u_2}, \frac{D}{\partial t} \frac{\partial \alpha}{\partial t} \right\rangle dt - \int_a^b \left\langle \frac{\partial \alpha}{\partial u_2}, \frac{D}{\partial u_1} \frac{D}{\partial t} \frac{\partial \alpha}{\partial t} \right\rangle dt \\ &\quad - \sum_{i=0}^N \left\langle \frac{D}{\partial u_1} \frac{\partial \alpha}{\partial u_2}, \Delta_{t_i} \frac{\partial \alpha}{\partial t} \right\rangle - \sum_{i=0}^N \left\langle \frac{\partial \alpha}{\partial u_2}, \frac{D}{\partial u_1} \Delta_{t_i} \frac{\partial \alpha}{\partial t} \right\rangle.\end{aligned}$$

Now when $u_1 = 0$ we have

$$\frac{D}{\partial t} \frac{\partial \alpha}{\partial t}(t, 0, 0) = 0 \quad \text{and} \quad \Delta_{t_i} \frac{\partial \alpha}{\partial t}(t, 0, 0) = 0,$$

since $t \mapsto \alpha(t, 0, 0) = \gamma(t)$ is a geodesic. So the first and third terms on the right side of equation (1) are zero for $u_1 = 0$. After a simple manipulation with

the fourth term we then have

$$(2) \quad \frac{\partial^2 E(\bar{\alpha}(u))}{\partial u_1 \partial u_2} \Big|_{(u_1, u_2)=(0,0)} = - \int_a^b \left\langle W_2(t), \frac{D}{\partial u_1} \frac{D}{\partial t} V \right\rangle dt \\ - \sum_{i=0}^N \left\langle W_2(t_i), \Delta_{t_i} \frac{DW_1}{dt} \right\rangle,$$

where all terms on the right are now evaluated at $(t, 0, 0)$. Now we can use Proposition II.6-10 to write

$$\frac{D}{\partial u_1} \frac{D}{\partial t} V - \frac{D}{\partial t} \frac{D}{\partial u_1} V = R \left(\frac{\partial \alpha}{\partial u_1}, \frac{\partial \alpha}{\partial t} \right) V = R(W_1, V) V.$$

Moreover, Proposition II.6-9 gives us

$$\frac{D}{\partial u_1} V = \frac{D}{\partial u_1} \frac{\partial \alpha}{\partial t} = \frac{D}{\partial t} \frac{\partial \alpha}{\partial u_1} = \frac{D}{dt} W_1,$$

so we have

$$\frac{D}{\partial u_1} \frac{D}{\partial t} V = \frac{D^2 W_1}{dt^2} + R(W_1, V) V.$$

Substituting into (2), we obtain the desired result. ♦

Suppose we are given two piecewise C^∞ vector fields W_1 and W_2 along a geodesic $\gamma: [a, b] \rightarrow M$. We can always find at least one variation α with these as variation vector fields, namely

$$\alpha(u_1, u_2, t) = \exp[u_1 W_1(t) + u_2 W_2(t)].$$

Extending the notation introduced previously, we define

$$E_{**}(W_1, W_2) = \frac{\partial^2 E(\bar{\alpha}(u))}{\partial u_1 \partial u_2} \Big|_{(u_1, u_2)=(0,0)},$$

for any variation α with variation vector fields W_1 and W_2 ; the second variation formula shows that $E_{**}(W_1, W_2)$ does not depend on the choice of α . The notation $E_{**}(W_1, W_2)$ is used *only* when W_1 and W_2 are vector fields along a *geodesic*; otherwise the second derivative will depend on the choice of α (compare pg. I.161 and Problem I.5-17). It is clear from the second variation formula that E_{**} is bilinear. It is also true that E_{**} is symmetric, $E_{**}(W_1, W_2) = E_{**}(W_2, W_1)$; this is not at all clear from the second variation formula, but it

follows immediately from the fact that $E(\bar{\alpha}(u))$ is a C^∞ function of u , and consequently

$$\frac{\partial^2 E(\bar{\alpha}(u))}{\partial u_1 \partial u_2} = \frac{\partial^2 E(\bar{\alpha}(u))}{\partial u_2 \partial u_1}.$$

The second variation formula reveals a hitherto unsuspected significance of curvature, and turns out to be responsible for many of the deeper consequences which we will be able to draw from assumptions about the curvature of M . We begin the program which will uncover these results by formulating questions about local minima for E in terms of E_{**} . Notice that if $\alpha: (-\varepsilon, \varepsilon) \times [a, b] \rightarrow M$ is a 1-parameter variation of γ , and we define a 2-parameter variation β by

$$\beta(u_1, u_2, t) = \alpha(u_1 + u_2, t),$$

then

$$\left. \frac{\partial^2 E(\bar{\alpha}(u))}{\partial u^2} \right|_{u=0} = \left. \frac{\partial^2 E(\bar{\beta}(u))}{\partial u_1 \partial u_2} \right|_{(u_1, u_2)=(0,0)}.$$

If γ has variation vector field W , then β clearly has variation vector fields $W_1 = W_2 = W$. Consequently,

$$\left. \frac{\partial^2 E(\bar{\alpha}(u))}{\partial u^2} \right|_{u=0} = E_{**}(W, W).$$

Thus, if γ is going to be a local minimum for energy, then we must have $E_{**}(W, W) \geq 0$ for all $W \in \Omega_\gamma$. Briefly expressed:

If γ is a local minimum, then E_{**} is positive semi-definite.

We also *hope* that γ actually will be a local minimum whenever we have the strict inequality $E_{**}(W, W) > 0$ for all non-zero $W \in \Omega_\gamma$. Briefly expressed:

If E_{**} is positive definite, then we *hope* that γ is a local minimum.

Our approach to this problem will be somewhat roundabout; we first investigate the vector fields $W \in \Omega_\gamma$ which satisfy $E_*(W, W) = 0$ for all $W \in \Omega_\gamma$, and hence represent something of a borderline between positive definiteness and positive semi-definiteness.

A piecewise C^∞ vector field W along γ is called a **Jacobi field** if it satisfies the “Jacobi equation”

$$\frac{D^2 W}{dt^2} + R(W, V)V = 0, \quad V = d\gamma/dt.$$

In a coordinate system this equation becomes a *linear* second order differential equation. Or, if we choose parallel vector fields Y_1, \dots, Y_n along γ which are orthonormal at 0, and hence orthonormal everywhere along γ , and set $W(t) = \sum_i f^i(t) Y_i(t)$, then our equation becomes

$$0 = \frac{d^2 f^i}{dt^2} + \sum_{j=1}^n a_j^i(t) f^j(t) \quad i = 1, \dots, n,$$

where $a_j^i = \langle R(Y_j, V)V, Y_i \rangle$. The solutions of this equation are everywhere C^∞ and, since the equation is linear, every solution can be defined on all of γ . It is also clear from the linearity of the equation that the set of all Jacobi fields W along γ forms a vector space. The dimension of this vector space is $2n$, since each Jacobi field W is determined by its initial conditions

$$W(0), \frac{DW}{dt}(0) \in M_{\gamma(0)}.$$

2. PROPOSITION. Let $\gamma: [a, b] \rightarrow M$ be a geodesic and let $W \in \Omega_\gamma$. Then W is a Jacobi field if and only if

$$E_{**}(W, W_2) = 0$$

for all $W_2 \in \Omega_\gamma$.

PROOF. If $W \in \Omega_\gamma$ is a Jacobi field, then the second variation formula shows immediately that

$$E_{**}(W, W_2) = - \int_a^b \langle W_2, 0 \rangle dt - \sum_{i=1}^{N-1} \langle W_2(t_i), 0 \rangle = 0.$$

Conversely, suppose that $W \in \Omega_\gamma$ and that $E_{**}(W, W_2) = 0$ for all $W_2 \in \Omega_\gamma$. Choose $a = t_0 < \dots < t_N = b$ so that each $W|_{[t_{i-1}, t_i]}$ is smooth, and let $f: [a, b] \rightarrow [0, 1]$ be a C^∞ function with $f(t_i) = 0$ and $f > 0$ otherwise. If we define

$$W_2 = f \cdot \left(\frac{D^2 W}{dt^2} + R(W, V)V \right),$$

then

$$0 = E_{**}(W, W_2) = - \int_a^b f \cdot \left\| \frac{D^2 W}{dt^2} + R(W, V)V \right\| dt - \sum_{i=0}^N \left\langle 0, \Delta_{t_i} \frac{DW}{dt} \right\rangle.$$

This implies that

$$(1) \quad \frac{D^2 W}{dt^2} + R(W, V)V = 0 \quad \text{on each } (t_{i-1}, t_i),$$

so each $W|_{[t_{i-1}, t_i]}$ is a Jacobi field.

Next choose W_2 to be any vector field along γ with $W_2(a) = W_2(b) = 0$ and $W_2(t_i) = \Delta_{t_i} DW/dt$ for $i = 1, \dots, N-1$. Then by (1) we have

$$0 = E_{**}(W, W_2) = - \int_a^b \langle W, 0 \rangle dt - \sum_{i=1}^N \left\| \Delta_{t_i} \frac{DW}{dt} \right\|^2,$$

so each $\Delta_{t_i} DW/dt = 0$. This means that the Jacobi fields $W|_{[t_{i-1}, t_i]}$ for two consecutive intervals have the same values of DW/dt on the intersection of the intervals. Since a Jacobi field is determined by its initial values, this shows that W is actually a Jacobi field on all of γ . ♦

Notice that there may not exist any non-trivial Jacobi fields W along γ which vanish at both a and b (indeed we hope to find conditions under which E_{**} is positive definite, which certainly excludes the possibility of non-zero Jacobi fields). When there is a non-zero Jacobi field W along γ with $W(a) = W(b) = 0$, we say that a and b are **conjugate values** along γ , and we define the **multiplicity** of a and b as conjugate values to be the dimension of the vector space consisting of all such Jacobi fields. We also say that $\gamma(a)$ and $\gamma(b)$ are **conjugate points** of γ , but this terminology is ambiguous when γ has self-intersections.

Since a Jacobi field W is determined by its initial values $W(a), DW/dt(a)$ at any point a , the multiplicity of two conjugate values a and b is clearly $\leq n$. Actually, it is always $\leq n-1$. To prove this, we just have to produce a Jacobi field along γ which is 0 at a but nowhere else. The vector field $W(t) = (t-a)V(t)$ has this property; it is a Jacobi field because

$$\begin{aligned} \frac{DW}{dt} &= V(t) + (t-a)\frac{DV}{dt} = V(t), \\ \frac{D^2 W}{dt^2} + R(W, V)V &= \frac{DV}{dt} + (t-a)R(V, V)V = 0. \end{aligned}$$

More generally, we have

3. PROPOSITION. Let γ be a geodesic, with velocity vector field $V = d\gamma/dt$.

(1) The vector field fV along γ is a Jacobi field if and only if f is linear.

- (2) Every Jacobi field W along γ can be written uniquely as $fV + W^\perp$, where f is linear and W^\perp is a Jacobi field perpendicular to γ .
- (3) If a Jacobi field W along γ is perpendicular to γ at two points a and b , then W is perpendicular to γ everywhere. In particular, if $W(a) = W(b) = 0$, then W is perpendicular to γ everywhere.

PROOF. (1) If $W = fV$, then $D^2W/dt^2 = f''V$, so the Jacobi equation for W is

$$0 = \frac{D^2W}{dt^2} + R(W, V)V = f''V + fR(V, V)V = f''V.$$

(2) Given a Jacobi field W along γ , we can write $W = fV + W^\perp$ for some f and some vector field W^\perp perpendicular to γ . The Jacobi equation for W gives

$$(a) \quad 0 = \frac{D^2W}{dt^2} + R(W, V)V = f''V + \frac{D^2W^\perp}{dt^2} + R(W^\perp, V)V.$$

Now

$$0 = \langle W^\perp, V \rangle \implies 0 = \left\langle \frac{DW^\perp}{dt}, V \right\rangle \implies 0 = \left\langle \frac{D^2W^\perp}{dt^2}, V \right\rangle$$

and we also have

$$0 = \langle R(W^\perp, V)V, V \rangle.$$

So (a) implies that $f'' = 0$, and therefore that W^\perp is a Jacobi field. Uniqueness is obvious.

(3) Write $W = fV + W^\perp$ as in (2). Then the linear function f must satisfy $f(a) = f(b) = 0$. So $f = 0$. ♦

Proposition 3 shows that for the purposes of investigating conjugate values, we need consider only perpendicular Jacobi fields. In particular, when M is a surface, and Y is a unit normal vector field along the geodesic $\gamma: [a, b] \rightarrow M$, any normal vector field W can be written uniquely as $W = gY$. We have $DY/dt = 0$, since γ is a geodesic and Y makes a constant angle with the parallel vector field $d\gamma/dt$. So the Jacobi equation for W becomes

$$g''(t)Y(t) + g(t)R(Y(t), V(t))V(t) = 0,$$

which is equivalent to

$$g''(t) + g(t)\langle R(Y(t), V(t))V(t), Y(t) \rangle = 0,$$

since we obtain $0 = 0$ when we take the inner product of the original equation with V . When the tangent vector $V = d\gamma/dt$ has length 1, we can write our equation as

$$g''(t) + K(\gamma(t)) \cdot g(t) = 0,$$

where K is the Gaussian curvature; this is the classical “Jacobi equation” for M .

The next theorem, basically due to Jacobi, gives a geometric way of obtaining Jacobi fields.

4. PROPOSITION. Let $\gamma: [a, b] \rightarrow M$ be a geodesic and let $\alpha: (-\varepsilon, \varepsilon) \times [a, b] \rightarrow M$ be a variation of γ through geodesics, so that each $\bar{\alpha}(u): [a, b] \rightarrow M$ is also a geodesic. Then the variation vector field $W(t) = \partial\alpha/\partial u(0, t)$ is a Jacobi field along γ .

PROOF. Since α is a variation of γ through geodesics, we have

$$\frac{D}{\partial t} \frac{\partial \alpha}{\partial t} = 0.$$

Therefore

$$\begin{aligned} 0 &= \frac{D}{\partial u} \frac{D}{\partial t} \frac{\partial \alpha}{\partial t} = \frac{D}{\partial t} \frac{D}{\partial u} \frac{\partial \alpha}{\partial t} + R\left(\frac{\partial \alpha}{\partial u}, \frac{\partial \alpha}{\partial t}\right) \frac{\partial \alpha}{\partial t} && \text{by Proposition II.6-10} \\ &= \frac{D^2}{\partial t^2} \frac{\partial \alpha}{\partial u} + R\left(\frac{\partial \alpha}{\partial u}, \frac{\partial \alpha}{\partial t}\right) \frac{\partial \alpha}{\partial t} && \text{by Proposition II.6-9,} \end{aligned}$$

which shows that $\partial\alpha/\partial u$ is a Jacobi field. ♦

Thus one way of obtaining Jacobi fields is to move geodesics around. In

particular, if γ is a great semi-circle on S^n , joining two antipodal points p and q , then a rotation of S^n keeping p and q fixed yields a variation vector field along γ which is a Jacobi field vanishing at p and q . Since we can rotate in $n - 1$ different directions, the points p and q have multiplicity $n - 1$, the theoretical maximum.

5. PROPOSITION. Every Jacobi field along a geodesic $\gamma: [a, b] \rightarrow M$ is the variation vector field of a variation of γ through geodesics.

PROOF. First suppose that γ lies completely inside an open set $U \subset M$ such that any two points $p, q \in U$ are joined by a unique geodesic in U , depending smoothly on p and q , of length $d(p, q)$. Given two vectors $W(a) \in M_{\gamma(a)}$ and $W(b) \in M_{\gamma(b)}$, choose curves $c_a, c_b: (-\varepsilon, \varepsilon) \rightarrow U$ such that

$$\begin{aligned} c_a(0) &= \gamma(a) & c_b(0) &= \gamma(b) \\ c_a'(0) &= W_a & c_b'(0) &= W_b. \end{aligned}$$

Define $\alpha: (-\varepsilon, \varepsilon) \times [a, b] \rightarrow M$ by letting $\bar{\alpha}: [a, b] \rightarrow M$ be the unique geodesic in U from $c_a(u)$ to $c_b(u)$ of length $d(c_a(u), c_b(u))$. Then $W(t) = \partial\alpha/\partial u(0, t)$ is a Jacobi field along γ , by Proposition 4. To show that all Jacobi fields arise in this way, simply consider the map

$$\Phi: \{\text{Jacobi fields along } \gamma\} \rightarrow M_{\gamma(a)} \oplus M_{\gamma(b)}$$

given by

$$W \mapsto (W(a), W(b)).$$

We have just shown that Φ is onto. Since the domain and range of Φ both have dimension $2n$, the linear map Φ must also be one-one. Thus W is determined by $W(a), W(b)$; this shows that when the above construction is applied to $W(a)$ and $W(b)$, the resulting Jacobi field $\partial\alpha/\partial u(0, t)$, obtained by a variation through geodesics, is precisely the given Jacobi field W .

For a general geodesic γ , we note that for sufficiently small δ , the restricted geodesic $\gamma|_{[a, a+\delta]}$ will lie in an appropriate set U , by Theorem I.9-14. This gives us a variation through geodesics $\alpha: (-\varepsilon, \varepsilon) \times [a, a+\delta]$ with $\partial\alpha/\partial u(0, t)$ equal to the given Jacobi field $W(t)$ for $t \in [a, a+\delta]$. Using compactness of $[a, b]$, it is easy to see that if ε is made sufficiently small, then each geodesic $\bar{\alpha}(u)$ can be extended to a geodesic $\bar{\bar{\alpha}}(u): [a, b] \rightarrow M$. Then $(u, t) \mapsto \bar{\bar{\alpha}}(u)(t)$ is the required variation through geodesics. ♦

An examination of the proof of Proposition 5 shows that if W is a Jacobi field along a geodesic $\gamma: [a, b] \rightarrow M$ with $W(a) = 0$, then we can even find a variation $\alpha: (-\varepsilon, \varepsilon) \times [a, b] \rightarrow M$ of γ through geodesics such that

$$\begin{aligned} \frac{\partial \alpha}{\partial u}(0, t) &= W(t) \\ \alpha(u, a) &= \gamma(a) \quad \text{for all } u \in (-\varepsilon, \varepsilon). \end{aligned}$$

However, if $W(b) = 0$ for some other point b , we may not be able to choose α so that we also have $\alpha(u, b) = \gamma(b)$ for all u ; we will merely have this condition “up to first order”, that is,

$$\frac{\partial \alpha}{\partial u}(0, b) = 0.$$

Thus a conjugate point of $p = \gamma(a)$ is a place where some 1-parameter family of geodesics starting from p “nearly” intersect. This description of conjugate

points shows why they should play such an important role in the study of local minima for length, for it is easy to give an intuitive argument to prove that a geodesic $\gamma: [a, b] \rightarrow M$ *cannot* locally minimize length if there is some $\tau \in (a, b)$ conjugate to a . In fact, suppose we have another geodesic η from $\gamma(a)$ to $\gamma(\tau)$ with nearly the same length as $\gamma|_{[a, \tau]}$. Then γ has nearly the same length as η followed by $\gamma|_{[\tau, b]}$. But this compound curve has a corner, and can clearly be

made shorter by replacing the corner with a minimal geodesic. Therefore, γ is *not* a curve of minimal length. This reasoning turns out to be perfectly valid, provided that one works infinitesimally:

6. **THEOREM.** Let $\gamma: [a, b] \rightarrow M$ be a geodesic, and suppose that there is a number $\tau \in (a, b)$ which is conjugate to a along γ . Then there is some $W \in \Omega_\gamma$ with $E_{**}(W, W) < 0$. Consequently, γ is *not* a local minimum for E .

PROOF. Since τ is conjugate to a along γ , there is a non-zero Jacobi field J along γ such that $J(a) = J(\tau) = 0$. Let \tilde{J} be the vector field along γ with

$$\begin{aligned}\tilde{J}(t) &= J(t) & a \leq t \leq \tau \\ \tilde{J}(t) &= 0 & \tau \leq t \leq b.\end{aligned}$$

Notice that the discontinuity of $D\tilde{J}/dt$ at τ is

$$\Delta_\tau \frac{D\tilde{J}}{dt} = \frac{DJ}{dt}(\tau) \neq 0,$$

the inequality following from the fact that $J(\tau) = 0$, but J is non-zero. Choose a vector field X along γ which vanishes at a and b and which satisfies

$$(1) \quad \langle X(\tau), \Delta_\tau D\tilde{J}/dt \rangle = 1.$$

Now let c be a small number and consider the vector field

$$W = \frac{1}{c}\tilde{J} - cX.$$

We have

$$E_{**}(W, W) = \frac{1}{c^2} E_{**}(\tilde{J}, \tilde{J}) - 2E_{**}(\tilde{J}, X) + c^2 E_{**}(X, X).$$

Using the second variation formula, this becomes

$$\begin{aligned}E_{**}(W, W) &= 0 - 2\langle X(\tau), \Delta_\tau D\tilde{J}/dt \rangle + c^2 E_{**}(X, X) \\ &= -2 + c^2 E_{**}(X, X) \quad \text{by (1).}\end{aligned}$$

For sufficiently small c this is negative, which proves the first part of the theorem.

We have really already observed that the first part of the theorem implies the second, but we repeat the reasoning here. Suppose we have $W \in \Omega_\gamma$ with $E_{**}(W, W) < 0$. Consider the variations

$$\begin{aligned}\alpha(u, t) &= \exp uW(t) \\ \beta(u_1, u_2, t) &= \alpha(u_1 + u_2, t) = \exp(u_1 + u_2)W(t).\end{aligned}$$

Then

$$\begin{aligned} \left. \frac{\partial^2 E(\bar{\alpha}(u))}{\partial u^2} \right|_{u=0} &= \left. \frac{\partial^2 E(\bar{\beta}(u))}{\partial u_1 \partial u_2} \right|_{(u_1, u_2)=(0,0)} \\ &= E_{**}(W, W) < 0. \end{aligned}$$

So $u \mapsto E(\bar{\alpha}(u))$ has a strict relative maximum at $u = 0$. Therefore γ is not a relative minimum for E . ♦

Notice that the first part of this proof makes crucial use of the discontinuity of DW/dt , which is closely related to the kink in the “intuitive proof”. (Once we have obtained this W , however, we can always smooth it out to obtain an everywhere C^∞ vector field W with $E_{**}(W, W) < 0$.)

Our next hope is that a geodesic *does* minimize length among nearby paths if there are no conjugate points. In order to consider this case, we first need a result which contains essentially the same information as Propositions 4 and 5, but in a form that is much easier to use; for simplicity, we state it for a geodesic defined on $[0, 1]$.

7. THEOREM. Let $\gamma: [0, 1] \rightarrow M$ be a geodesic with $\gamma(0) = p \in M$ and $\gamma'(0) = v \in M_p$, so that γ can be described as $t \mapsto \exp tv$ for the map

$$\exp = \exp_p: M_p \rightarrow M.$$

Then 0 and 1 are conjugate values for γ if and only if v is a critical point of \exp .

PROOF. Suppose that v is a critical point for \exp . Then $\exp_*(X) = 0$ for some non-zero $X \in (M_p)_v =$ the tangent space of M_p at v . Let c be a path in M_p with $c(0) = v$ and $c'(0) = X$, and define

$$\alpha(u, t) = \exp tc(u) \quad 0 \leq t \leq 1.$$

Then α is a variation of γ through geodesics, so the vector field

$$W(t) = \left. \frac{\partial}{\partial u} \right|_{u=0} \exp tc(u)$$

is a Jacobi field along γ . We clearly have $W(0) = 0$, and also

$$\begin{aligned} W(1) &= \left. \frac{\partial}{\partial u} \right|_{u=0} \exp c(u) = \exp_* c'(0) \\ &= \exp_* X = 0. \end{aligned}$$

Moreover,

$$\begin{aligned}
 \frac{DW}{dt}(0) &= \frac{D}{\partial t} \Big|_{t=0} \frac{\partial}{\partial u} \Big|_{u=0} \exp tc(u) \\
 &= \frac{D}{\partial u} \Big|_{u=0} \frac{\partial}{\partial t} \Big|_{t=0} \exp tc(u) \quad \text{by Proposition II.6-9} \\
 &= \frac{D}{\partial u} \Big|_{u=0} c(u);
 \end{aligned}$$

this last expression is the covariant derivative of the vector field $u \mapsto c(u)$ along the constant curve $u \mapsto p$. Hence

$$\frac{DW}{dt}(0) = c'(0) = X \neq 0.$$

In particular, W is not identically 0, which shows that 0 and 1 are conjugate values for γ .

Now suppose that v is not a critical point for \exp . If $X_1, \dots, X_n \in (M_p)_v$ are n linearly independent vectors, then $\exp_*(X_1), \dots, \exp_*(X_n) \in M_{\gamma(1)}$ are also linearly independent. Choose paths c_1, \dots, c_n in M_p with $c_i(0) = v$ and $c_i'(0) = X_i$, and consider the variations

$$\alpha_i(u, t) = \exp tc_i(u),$$

with variation vector fields W_i . Then the W_i are Jacobi fields along γ which vanish at 0. Moreover, the $W_i(1) = \exp_*(X_i)$ are independent, so no non-trivial linear combination of the W_i can vanish at 1. Since the vector space of Jacobi fields along γ which vanish at 0 has dimension exactly n , it follows that no non-zero Jacobi field along γ vanishes at 0 and also at 1. ♦

Since the points in M_p where \exp_* is zero form a closed set, Theorem 7 shows that the numbers τ conjugate to 0 along a geodesic $\gamma: [0, \infty) \rightarrow M$ also form a closed set. In particular, if there is any such τ , then there is a *first* τ conjugate to 0. Actually, much more is true, for the set of τ conjugate to 0 consists only of isolated points, so there are only finitely many τ conjugate to 0 in any interval $[0, b]$. We will not prove this here, but it is included in another result which we will state later on.

It is now a simple matter to prove the local length-minimizing property of a geodesic $\gamma: [a, b] \rightarrow M$ satisfying the condition that no number $\tau \in (a, b]$ is a conjugate value of a along γ . For simplicity, we will call such a γ a geodesic “without conjugate points”.

8. THEOREM. Let $\gamma: [a, b] \rightarrow M$ be a one-one geodesic with no conjugate points. Then γ has strictly smaller length than all sufficiently nearby paths between $p = \gamma(a)$ and $q = \gamma(b)$ (except for those which are merely reparameterizations of γ).

PROOF. By reparameterizing, we may assume that $[a, b] = [0, 1]$. If $v = \gamma'(0)$, then by Theorem 7 the map $\exp = \exp_p: M_p \rightarrow M$ is regular on the set $\{tv : 0 \leq t \leq 1\} \subset M_p$. By Lemma I.9-19 there is an open set $U \supset L$ on which \exp is a diffeomorphism. The result then follows from Problem I.9-29. ♦

Remark: Theorem 8 clearly remains true even for geodesics γ with self-intersections, provided that “nearby” paths refer to paths c with $c(t)$ close to $\gamma(t)$ for all t .

Let us test out Theorems 6 and 8 on the 2-sphere $S^2(r)$ of radius r , with $\gamma: [0, L] \rightarrow S^2(r)$ a portion of a great circle starting from a point p . We take γ

to be parameterized by arclength, so that $V = d\gamma/dt$ has length 1. Proposition 3(3) shows that in order to investigate conjugate points along γ , it suffices to consider Jacobi fields which are perpendicular to γ . If Y is a unit normal vector field along γ , then the Jacobi equation for $W = gY$ is (compare page 211)

$$g''(t) + \frac{1}{r^2}g(t) = 0.$$

The solutions vanishing at $t = 0$ are all multiples of

$$g(t) = \sin \frac{t}{r},$$

which has its first positive 0 at πr . So if $L > \pi r$, then γ contains a conjugate point, and Theorem 6 shows that γ does not locally minimize length. This is easy to see from the picture; in fact, in this case the intuitive proof of Theorem 6 works exactly. If $L < \pi r$, then Theorem 8 shows that γ does locally minimize length.

We have exactly the same situation for any compact surface of revolution M , when we take p to be one of the points where M intersects the z -axis I_z . The

geodesics through p are the meridians, and it is clear, just by looking at the picture, that the only point conjugate to p along any geodesic is the other point q of $M \cap I_z$. Geodesics which do not reach q are local strict minima for length, and geodesics which extend past q are not local minima.

In this example it is clear that a geodesic γ which does not reach q is actually a minimum among all paths. [Proof: A minimum path between p and the other end of γ exists, since M is complete, and this path must be a geodesic; we know what all geodesics through p are, and γ is clearly the shortest.] However, it is easy to concoct examples where the non-existence of conjugate points implies only that γ is a *local* minimum for E . For example, we can round off the edges of the surface shown below (the boundary of part of a spherical wedge). Since

the surface is a sphere in a neighborhood of γ , it is still the case that no two points of γ are conjugate, and Theorem 8 still applies. On the other hand, there is clearly a shorter path between p and q if the wedge is thin enough.

A little more interesting situation arises for an ellipsoid. For the geodesic γ shown below, the first point q conjugate to p along γ occurs past the point p'

on the opposite end of the axis. (To establish this fact one has to examine the Jacobi equations for γ with some care.) If r is a point between p' and q , then the portion of γ between p and r is a local minimum for E , but clearly not a global minimum, since the extension γ' of γ in the other direction past p has shorter length from p to r (on the other hand, γ' is the only other geodesic from p to r which is shorter than γ).

Notice that Theorems 6 and 8 do not cover the case where b is the only point in $(a, b]$ which is conjugate to a . This is the borderline case for which no conclusions can be drawn. It may happen, first of all, that γ is a local minimum for length, but not a strict local minimum. This is illustrated, of course, by taking γ to be half of a great circle on the sphere S^2 . Now consider an ellipsoid, with three unequal axes $a > b > c$, and let p be a point at one end of the largest axis. The figure on the opposite page shows the conjugate points of the geodesics starting from p (it is the envelope of these geodesics—compare the Addendum to Chapter 3); this set is a curve with four cusps. The geodesic from p to A is a strict global minimum, while the geodesic going from p to p' and then on to B is a strict local minimum.

The next result complements Theorem 8 so that it appears to parallel Theorem 6 more closely.

9. PROPOSITION. Let $\gamma: [a, b] \rightarrow M$ be a geodesic without conjugate points. Then $E_{**}(W, W) > 0$ for every non-zero $W \in \Omega_\gamma$.

PROOF. Theorem 8 (and the Remark following it) implies that $E_{**}(W, W) \geq 0$. For if $E_{**}(W, W) < 0$, then γ would not be a local minimum for E (by the argument in the proof of Theorem 6).

Now suppose we had $E_{**}(W_1, W_1) = 0$ for some non-zero $W_1 \in \Omega_\gamma$. Then for any $W_2 \in \Omega_\gamma$ we would have

$$\begin{aligned} 0 &\leq E_{**}(W_1 + cW_2, W_1 + cW_2) \\ &= 0 + 2c E_{**}(W_1, W_2) + c^2 E_{**}(W_2, W_2). \end{aligned}$$

Since this is supposed to be true for all c , it is clear that we would have to have $E_{**}(W_1, W_2) = 0$. Thus W_1 would be a Jacobi field, contradicting the fact that b is not a conjugate value of a . ♦

More generally, we have the following result, which plays an important role later on.

10. COROLLARY. Let $\gamma: [a, b] \rightarrow M$ be a geodesic without conjugate points, W a Jacobi field along γ , and X a piecewise C^∞ vector field along γ

with

$$X(a) = W(a), \quad X(b) = W(b).$$

Then

$$E_{**}(X, X) \geq E_{**}(W, W),$$

and equality holds only when $X = W$.

PROOF. The second variation formula shows that for all piecewise C^∞ vector fields W_2 along γ we have

$$(1) \quad E_{**}(W, W_2) = \left\langle W_2, \frac{DW}{dt} \right\rangle \Big|_a^b = \left\langle W_2(b), \frac{DW}{dt}(b) \right\rangle - \left\langle W_2(a), \frac{DW}{dt}(a) \right\rangle.$$

Moreover, since $X - W \in \Omega_\gamma$, Proposition 9 shows that

$$\begin{aligned} 0 &\leq E_{**}(X - W, X - W) \\ &= E_{**}(X, X) + E_{**}(W, W) - 2E_{**}(W, X) \\ &= E_{**}(X, X) + \left\langle W, \frac{DW}{dt} \right\rangle \Big|_a^b - 2 \left\langle X, \frac{DW}{dt} \right\rangle \Big|_a^b \quad \text{by (1)} \\ &= E_{**}(X, X) - \left\langle W, \frac{DW}{dt} \right\rangle \Big|_a^b \quad \text{since } W = X \text{ at } a \text{ and } b \\ &= E_{**}(X, X) - E_{**}(W, W) \quad \text{by (1) again.} \end{aligned}$$

Moreover, it is clear that equality holds only if $X - W = 0$. ♦

Theorem 6 and Proposition 9 show that for a geodesic $\gamma: [a, b] \rightarrow M$, the existence of conjugate points is practically equivalent to the existence of vector fields $W \in \Omega_\gamma$ with $E_{**}(W, W) < 0$:

- (A) If there is some $\tau \in (a, b)$ conjugate to a , then there is some $W \in \Omega_\gamma$ with $E_{**}(W, W) < 0$ (Theorem 6);
- (B) If there is some $W \in \Omega_\gamma$ with $E_{**}(W, W) < 0$, then there is some $\tau \in (a, b]$ conjugate to a (Proposition 9).

We will see later that it can be very convenient to replace questions about conjugate points by questions about vector fields $W \in \Omega_\gamma$ with $E_{**}(W, W) < 0$. Actually, the situation is even better than we have indicated, because statement (B) can be strengthened: if $E_{**}(W, W) < 0$ for some $W \in \Omega_\gamma$, then there is $\tau \in (a, b)$ conjugate to a . In fact, there is a far-reaching generalization of

these results. We say that E_{**} is **negative definite** on a subspace $\mathcal{V} \subset \Omega_\gamma$ if $E_{**}(W, W) < 0$ for all non-zero $W \in \mathcal{V}$, and we define the **index** of E_{**} to be the largest dimension of any subspace $\mathcal{V} \subset \Omega_\gamma$ on which E_{**} is negative definite (compare page 3). Then we have the celebrated

MORSE INDEX THEOREM. The index of E_{**} for a geodesic $\gamma: [a, b] \rightarrow M$ is the number of $\tau \in (a, b)$ which are conjugate to a , each conjugate value being counted with its multiplicity. This index is always finite.

In terms of the index of E_{**} , our Theorem 6 can be reformulated as follows: if the number of conjugate values is ≥ 1 , then the index is ≥ 1 . For the Morse Index Theorem we need the more general assertion, that the index of $(E_a^t)_{**}$ increases by at least ν as t passes a conjugate value τ with multiplicity ν . This is the *only* point in the proof that does not involve simple general considerations, and it may be handled by essentially the same trick which was used in the present proof of Theorem 6. I hope that by clearing this path right up to the proof of the Index Theorem, I may have enticed you into reading the proof in Milnor {2}, which also describes some of the beautiful applications of these differential geometric ideas to topology.

In order to obtain interesting differential geometric consequences of our foundational results, we need to find hypotheses which imply something about the solutions of Jacobi equations. These hypotheses usually involve the sectional curvature $K(P)$ of 2-dimensional subspaces $P \subset M_p$; recall that $K(P) = \langle R(X, Y)Y, X \rangle$ for orthonormal $X, Y \in P$. Clearly all sectional curvatures of M are ≤ 0 if and only if $\langle R(X, Y)Y, X \rangle \leq 0$ for all pairs X, Y of vectors at the same point of M .

11. PROPOSITION. If all sectional curvatures of M are ≤ 0 , then no two points of M are conjugate along any geodesic.

PROOF. If γ is a geodesic with velocity vector field $V = d\gamma/dt$, and W is a Jacobi field along γ , then

$$\frac{D^2 W}{dt^2} + R(W, V)V = 0,$$

so

$$\left\langle \frac{D^2 W}{dt^2}, W \right\rangle = -\langle R(W, V)V, W \rangle \geq 0.$$

Therefore

$$\frac{d}{dt} \left\langle \frac{DW}{dt}, W \right\rangle = \left\langle \frac{D^2 W}{dt^2}, W \right\rangle + \left\langle \frac{DW}{dt}, \frac{DW}{dt} \right\rangle \geq 0,$$

which means that $\langle DW/dt, W \rangle$ is increasing.

Now if W vanishes at two points, t_0 and t_1 , then $\langle DW/dt, W \rangle$ vanishes at t_0 and t_1 , so $\langle DW/dt, W \rangle$ must be 0 on the interval $[t_0, t_1]$. This clearly implies that DW/dt also vanishes at t_0 . Hence $W = 0$. ♦

Although Proposition 11 shows that all geodesic segments on M are local minima for length, this does not mean that they are necessarily global minima. In fact, if we consider a compact surface M with everywhere negative curvature (Chapter 6, Addendum 1), it is clear that no geodesic $\gamma: \mathbb{R} \rightarrow M$ can be a global minimum for length on arbitrarily large segments.

The most interesting consequence of Proposition 11 is obtained by combining it with the following general result.

12. THEOREM. Let M be a complete, connected, n -dimensional Riemannian manifold, and let p be a point of M such that no point of M is conjugate to p along any geodesic. Then $\exp = \exp_p: M_p \rightarrow M$ is a covering map. In particular, if M is simply-connected, then M is diffeomorphic to \mathbb{R}^n .

13. COROLLARY (HADAMARD-CARTAN). A complete, simply-connected, n -dimensional Riemannian manifold with all sectional curvatures ≤ 0 is diffeomorphic to \mathbb{R}^n .

PROOF. The Corollary follows immediately from the Theorem and Proposition 11. To prove the Theorem, let $\langle \cdot, \cdot \rangle$ be the Riemannian metric on M , and consider the tensor $\exp^*\langle \cdot, \cdot \rangle$ on M_p . Since there are no points conjugate to p , the map \exp_* is always one-one, so $\exp^*\langle \cdot, \cdot \rangle$ is a Riemannian metric on M_p . We claim that M_p is complete in the metric $\exp^*\langle \cdot, \cdot \rangle$. To prove this, we just note that the straight lines through 0 in M_p are clearly geodesics for the metric $\exp^*\langle \cdot, \cdot \rangle$, since their images under the local isometry $\exp: M_p \rightarrow M$ are geodesics in M . Since all geodesics through $0 \in M_p$ can be defined for all t , it follows from Problem I.9-43 that M_p is complete. The Theorem then follows from

14. LEMMA. Let M and N be connected Riemannian manifolds with M complete, and let $\phi: M \rightarrow N$ be a local isometry. Then N is complete and ϕ is a covering map onto N .

PROOF. Let $p_0 \in M$. Given a geodesic $\gamma: (-\varepsilon, \varepsilon) \rightarrow N$ with $\gamma(0) = \phi(p_0)$, let c be the geodesic in M with $c(0) = p_0$ and $\phi_*c'(0) = \gamma'(0)$. Then $\gamma = \phi \circ c$,

since ϕ is a local isometry. Since c can be defined on all of \mathbb{R} , we can extend γ to all of \mathbb{R} as $\phi \circ c$. Thus N is complete, by Problem I.9-43.

To prove that ϕ is onto N it suffices to prove that $\phi(M)$ is closed (for $\phi(M)$ is open, since ϕ is everywhere regular). Let $q \in \overline{\phi(M)}$, and let V be a convex neighborhood of 0 in N_q on which \exp_q is a diffeomorphism. There is a point $q' \in \exp_q(V)$ of the form $q' = \phi(p')$ for $p' \in M$. Let γ be the geodesic in $\exp_q(V)$ with $\gamma(0) = q'$ and $\gamma(1) = q$. Consider the geodesic c in M with $c(0) = p'$ and $\phi_*c'(0) = \gamma'(0)$. Then $\gamma = \phi \circ c$, as before. The point $p = c(1)$ is defined and $\phi(p) = \phi(c(1)) = \gamma(1) = q$. Thus $\overline{\phi(M)} \subset \phi(M)$, so $\phi(M)$ is closed. Hence ϕ is onto N .

The proof that ϕ is a covering map will be similar to the proof that appears on pp. III.258–259. For fixed $q \in N$, let

$$V = \{Y \in N_q : \|Y\| < 2\varepsilon\} \subset N_q$$

be a neighborhood of 0 in N_q on which \exp_q is a diffeomorphism. Suppose that $p \in \phi^{-1}(q)$. Consider the map

$$\begin{aligned} f &= \exp_p \circ \phi_{p*}^{-1} \circ (\exp_q(V))^{-1}, \\ f: \exp_q(V) &\rightarrow \exp_p(\{X \in M_p : \|X\| < 2\varepsilon\}) \subset M; \end{aligned}$$

this map is defined since M is complete. It is easy to see that

$$\phi: \exp_p(\{X \in M_p : \|X\| < 2\varepsilon\}) \rightarrow \exp_q(V)$$

is a diffeomorphism with inverse f . Now let

$$W = \exp_q(\{Y \in N_q : \|Y\| < \varepsilon\}) \subset N,$$

and for each $p \in M$, let

$$W_p = \exp_p(\{X \in M_p : \|X\| < \varepsilon\}) \subset M.$$

We claim that

$$\phi^{-1}(W) = \bigcup_{p \in \phi^{-1}(q)} W_p.$$

In fact, given $p' \in \phi^{-1}(W)$, let γ be the geodesic in W of length $d(\phi(p'), q)$ with $\gamma(0) = \phi(p')$ and $\gamma(1) = q$. Let c be the geodesic with $c(0) = p'$ and $\phi_*c'(0) = \gamma'(0)$. Then c is defined on $[0, 1]$, since M is complete, and $\phi \circ c = \gamma$ on $[0, 1]$. In particular, $p = c(1) \in \phi^{-1}(q)$, and it is easy to see that all points of $c([0, 1])$ are in W_p . Thus $p' = c(0) \in W_p$.

To complete the proof we just have to show that the W_p are disjoint. Now if $W_{p_1} \cap W_{p_2} \neq \emptyset$, then we clearly have

$$p_2 \in \exp_{p_1}(\{X \in M_{p_1} : \|X\| < 2\varepsilon\}).$$

But we know that ϕ is a diffeomorphism on this set. Since $\phi(p_1) = \phi(p_2)$, it follows that $p_1 = p_2$. ♦

Proposition 11 is but a special case of more general results involving manifolds whose sectional curvatures satisfy certain inequalities. These results all follow from one theorem, but the mere statement of this theorem tends to overwhelm one with its complexity. So we will approach it rather gingerly by first proving special cases, all of which represent important steps in the historical evolution of the final result.

The first theorem of this type depends on a surprisingly simple proposition about second order differential equations. Remember that a solution ϕ of such an equation is determined by $\phi(a)$ and $\phi'(a)$. Consequently, a non-zero solution ϕ must have isolated zeros.

15. THEOREM (THE STURM COMPARISON THEOREM). Let f and h be two continuous functions satisfying $f(t) \leq h(t)$ for all t in an interval I , and let ϕ and η be two functions satisfying the differential equations

$$\begin{aligned} (1) \quad & \phi'' + f\phi = 0 \\ (2) \quad & \eta'' + h\eta = 0 \end{aligned}$$

on I . Assume that ϕ is not the zero function, and let $a, b \in I$ be two consecutive zeros of ϕ .

(1) The function η must have a zero in (a, b) , unless $f = h$ everywhere on $[a, b]$ and η is a constant multiple of ϕ on $[a, b]$.

(2) Suppose that we have $\eta(a) = 0$, and also $\eta'(a) = \phi'(a) > 0$ [which can be achieved by choosing a suitable multiple of η , and changing ϕ to $-\phi$, if necessary]. If τ is the smallest zero of η in $(a, b]$, then

$$\phi(t) \geq \eta(t) \quad \text{for } a \leq t \leq \tau,$$

and equality holds for some t only if $f = h$ on $[a, t]$.

PROOF. Equations (1) and (2) give

$$(3) \quad \phi''\eta - \eta''\phi = (h - f)\phi\eta.$$

Suppose that η were nowhere zero on (a, b) . It is easy to see that there is no loss of generality in assuming that

$$(4) \quad \eta, \phi > 0 \quad \text{on } (a, b).$$

Then (3) gives

$$0 \leq \phi''\eta - \eta''\phi,$$

so

$$(5) \quad 0 \leq \int_a^b \phi''\eta - \eta''\phi = \int_a^b (\phi'\eta - \eta'\phi)' \\ = \phi'(b)\eta(b) - \phi'(a)\eta(a), \quad \text{since } \phi(a) = \phi(b) = 0.$$

On the other hand, (4) clearly implies that

$$(6) \quad \left\{ \begin{array}{l} \phi'(a) > 0, \phi'(b) < 0 \\ \eta(a), \eta(b) \geq 0 \end{array} \right\} \implies \phi'(b)\eta(b) - \phi'(a)\eta(a) \leq 0.$$

If $f \neq h$, then we actually have strict inequality in (5), which contradicts the second part of (6). This contradiction shows that η must have a zero on (a, b) .

If $f = h$ on $[a, b]$, then equality holds in (5), and the first part of (6) implies that we must have $\eta(a) = \eta(b) = 0$. Since ϕ and η then satisfy the same second order equation on $[a, b]$ and $\phi(a) = \eta(a)$, the solution η must be a constant multiple of ϕ on $[a, b]$.

Now suppose that $\eta(a) = 0$ and $\eta'(a) = \phi'(a) > 0$. If τ is the smallest zero of η in $(a, b]$, then $\phi, \eta > 0$ on (a, τ) , so (3) gives

$$0 \leq \phi''\eta - \eta''\phi = (\phi'\eta - \eta'\phi)' \quad \text{on } (a, \tau).$$

This implies that

$$0 \leq \phi'\eta - \eta'\phi \quad \text{on } (a, \tau),$$

since $[\phi'\eta - \eta'\phi](a) = 0$. Using positivity of η on (a, τ) again, this gives

$$(7) \quad 0 \leq \left(\frac{\phi}{\eta} \right)' \quad \text{on } (a, \tau).$$

But

$$\begin{aligned}\lim_{t \rightarrow a} \frac{\phi(t)}{\eta(t)} &= \lim_{t \rightarrow a} \frac{\phi'(t)}{\eta'(t)} && \text{by L'Hôpital's Rule} \\ &= 1, && \text{by assumption.}\end{aligned}$$

Therefore

$$\frac{\phi}{\eta} \geq 1 \quad \text{on } (a, \tau),$$

which is the desired inequality. The proof of the final statement is left to the reader. ♦

Remark 1: Since $\phi'(a)$ and $\eta'(a)$ exist, and $\eta'(a) \neq 0$, we really used only a trivial case of L'Hôpital's Rule; we could have simply written

$$\begin{aligned}\lim_{t \rightarrow a} \frac{\phi(t)}{\eta(t)} &= \lim_{t \rightarrow a} \frac{\phi(t) - \phi(a)}{\eta(t) - \eta(a)} = \lim_{t \rightarrow a} \frac{\frac{\phi(t) - \phi(a)}{t - a}}{\frac{\eta(t) - \eta(a)}{t - a}} \\ &= \frac{\phi'(a)}{\eta'(a)} = 1.\end{aligned}$$

Remark 2: In our applications, we will be interested only in the case where $\eta(a) = 0$. The reasoning for part (1) is then unnecessary, because part (2) shows that $\phi \geq \eta$ on any interval (a, τ) on which $\phi, \eta > 0$; this clearly implies that η vanishes somewhere on $(a, b]$. Moreover, if b were the first zero of η , then we would have $\phi(b) = \eta(b) = 0$, so we would have $f = h$ on $[a, b]$, by the final statement in part (2). Nevertheless, part (1) is still of interest; here is one consequence:

16. COROLLARY. If ϕ_1 and ϕ_2 are two linearly independent solutions of the equation

$$\phi'' + f\phi = 0,$$

then the zeros of ϕ_1 alternate with the zeros of ϕ_2 .

A particularly simple instance of Corollary 16 is provided by the equation $y'' + y/r^2 = 0$, where $r > 0$ is a constant. The solutions of this equation can all be written in the form $y(t) = b \sin(a + t/r)$. The zeros are always πr apart, so the zeros of two linearly independent solutions alternate with each other. This simple equation serves as a standard with which we can compare the Jacobi equation.

17. **THEOREM (BONNET).** Let M be a surface, and $\gamma: [0, L] \rightarrow M$ a geodesic parameterized by arclength. Let $r > 0$ be a constant.

(1) If $K(p) \leq 1/r^2$ for all $p = \gamma(t)$, and γ has length $L < \pi r$, then γ contains no conjugate points.

(2) If $K(p) \geq 1/r^2$ for all $p = \gamma(t)$, and γ has length $L > \pi r$, then there is a point $\tau \in (0, L)$ conjugate to 0, and therefore γ is not of minimal length.

(3) If M is connected and complete, and $K(p) \geq 1/r^2$ for all $p \in M$, then M is actually compact, with diameter $\leq \pi r$.

PROOF. (1) Let Y be a unit vector field along γ with $\langle V, Y \rangle = 0$, where V is the unit vector field $V = d\gamma/dt$. The Jacobi equation for the vector field ϕY is (compare page 211)

$$\phi''(t) + K(\gamma(t)) \cdot \phi(t) = 0.$$

The simpler equation

$$\eta''(t) + \frac{1}{r^2} \eta(t) = 0$$

has the solution $\eta(t) = \sin t/r$. Since $K(\gamma(t)) \leq 1/r^2$ by hypothesis, the Sturm comparison theorem shows that the first equation cannot have a solution ϕ vanishing at 0 and at $L < \pi r$, since η has no zero in $(0, L)$.

(2) Let Y be as in part (1), and consider a vector field ηY . The Jacobi equation for ηY is

$$\eta''(t) + K(\gamma(t)) \cdot \eta(t) = 0,$$

and the simpler equation

$$\phi''(t) + \frac{1}{r^2} \phi(t) = 0$$

has the solution $\phi(t) = \sin t/r$ which vanishes at 0 and at πr . Since $1/r^2 \leq K(\gamma(t))$, the comparison theorem shows that any Jacobi field ηY must have a zero on the open interval $(0, \pi r) \subset (0, L)$. So if we choose any non-zero Jacobi field ηY along γ with $\eta(0) = 0$, then this Jacobi field will also vanish at some $\tau \in (0, L)$; thus τ is conjugate to 0.

(3) Any two points $p, q \in M$ can be joined by a geodesic γ of minimal length (Theorem I.9-18). Then the length of γ must be $\leq \pi r$, by part (2). So M is bounded, with diameter $\leq \pi r$. Since closed bounded sets in a complete manifold are compact, it follows that M itself is compact. ♦

I do not know whether Sturm ever saw this beautiful application of his theorem (he died in 1855, the same year that Bonnet published the result), but in his lectures he is supposed to have referred to it as the theorem “whose name I have the honor to bear”.

Bonnet’s Theorem fairly cries out to be generalized to higher dimensional manifolds, but a direct approach leads us into difficulties. The single normal vector field Y along γ has to be replaced by $n - 1$ vector fields Y_1, \dots, Y_{n-1} . Even if we choose Y_1, \dots, Y_{n-1} to be parallel, everywhere orthonormal vector fields along γ , the Jacobi equation for $\sum_i \phi_i Y_i$ reads

$$\sum_i \phi_i''(t) Y_i(t) + \sum_i \phi_i(t) \cdot R(Y_i(t), V(t)) V(t) = 0,$$

which is equivalent to a *system* of ordinary differential equations

$$\phi_j''(t) + \sum_i \phi_i(t) \langle R(Y_i(t), V(t)) V(t), Y_j(t) \rangle = 0,$$

and these equations do not even involve the sectional curvature directly. It is clear that we will have to approach this problem with a little more finesse.

One way to extend the results of Bonnet’s theorem to higher dimensions is by an artful use of Synge’s inequality (Corollary 1-7). Suppose first that $K(P) \geq 1/r^2$ for all 2-dimensional $P \subset M_{\gamma(t)}$, and that $\gamma: [0, L] \rightarrow M$ has length $L > \pi r$. Let Y be a *parallel* vector field along γ which is everywhere perpendicular to the parallel vector field $V = d\gamma/dt$, and let $S \subset M$ be a surface containing γ whose tangent space at each point $\gamma(t)$ is spanned by $V(t)$ and $Y(t)$. Then

Synge’s inequality shows that the Gaussian curvature of S at $\gamma(t)$ is the same as the sectional curvature of M for the plane spanned by $V(t)$ and $Y(t)$. So the Gaussian curvature of S at $\gamma(t)$ is $\geq 1/r^2$. Bonnet’s theorem then shows that there is a point $\tau \in (0, L)$ conjugate to 0 along γ . Of course, this means that τ is a conjugate value for 0 *in the surface* S . To conclude that there is a

conjugate value in M itself, we must use the following indirect line of reasoning: Since $\tau \in (0, L)$ is a conjugate value for 0 in S , the geodesic γ is *not* a local minimum for length in S . Therefore it is certainly not a local minimum for length in M . Therefore, some $\sigma \in (0, L]$ must be a conjugate value for 0 in M . Applying this result to $\gamma|_{[0, L']}$ for $\pi r < L' < L$, we see that actually some $\sigma \in (0, L'] \subset (0, L)$ is conjugate to 0 along γ in M .

In the previous paragraph, we had to choose the surface S so as not to decrease K , and then we had to show that the choice of S made no difference for the final conclusion. If we instead try to analyze the case where $K(P) \leq 1/r^2$ and γ has length $L < \pi r$, then we certainly don't care whether K is decreased, but our choice of S will be much more dependent on the desired conclusion. Suppose, then, that γ contained a conjugate point $\tau \in (0, L]$. We might as well assume that L itself is conjugate to 0 along γ , since we can always work with $\gamma|_{[0, \tau]}$; for the same reason, we might as well assume that L is the smallest value conjugate to 0. Then there is a variation α of γ through geodesics in M , whose variation vector field $W(t) = \partial\alpha/\partial u(0, t)$ vanishes only at 0 and L . Consider the surface S formed by the image of α . Synge's inequality shows that the

Gaussian curvature of S is $\leq 1/r^2$ along γ , and then Bonnet's theorem shows that γ cannot contain a conjugate point on S . But γ clearly does contain a conjugate point on S , because the $\bar{\alpha}(u)$ are also geodesics on S , so the variation vector field of α is also a Jacobi field along γ on S . We seem to have obtained a contradiction, and thereby shown that γ cannot contain a conjugate point $\tau \in (0, L]$. The trouble with this argument is that only an excess of generosity could lead one to call S a surface, as the map α is definitely *not* an immersion at $(0, 0)$ or $(0, L)$. The idea of the proof is basically sound, however, and leads to the desired result if one reasons a little more carefully (Problem 2).

We have not bothered to bestow upon this reasoning the dignity which might accrue to it as the official proof of a theorem, because the results, and even better ones, can be obtained in a more systematic way. In fact, we shall present

two new methods of generalizing Bonnet's theorem. These two methods differ significantly in their basic philosophy, but they both depend on a certain construction, similar to one used above, which is best set forth in a separate Lemma. This very general sounding Lemma involves geodesics in two different manifolds, although in applications one of the two is always taken to be a sphere. (In the statement and proof of the Lemma, we will not use subscripts to distinguish the norms $\| \cdot \|$ and covariant derivatives D/dt in the two manifolds, since it should always be clear which manifold we are working in.)

18. LEMMA. Let M_1 and M_2 be two manifolds of the same dimension n , and let $\gamma_i: [a, b] \rightarrow M_i$ be arclength parameterized geodesics in these two manifolds. Then there is a vector space isomorphism

$$\begin{aligned} \Phi: \{\text{piecewise } C^\infty \text{ vector fields along } \gamma_1\} \\ \rightarrow \{\text{piecewise } C^\infty \text{ vector fields along } \gamma_2\} \end{aligned}$$

such that for all $t \in [a, b]$ we have

- (1) If $\frac{DX}{dt}$ is continuous at t , then $\frac{D\Phi(X)}{dt}$ is continuous at t ,
- (2) $\langle X(t), \gamma_1'(t) \rangle = \langle \Phi(X)(t), \gamma_2'(t) \rangle$,
- (3) $\|X(t)\| = \|\Phi(X)(t)\|$,
- (4) $\left\| \frac{DX}{dt}(t) \right\| = \left\| \frac{D\Phi(X)}{dt}(t) \right\|$,

it being understood that the last equation refers to left and right hand limits at discontinuity points.

PROOF. Pick some fixed $t_0 \in [a, b]$. Let $\phi: (M_1)_{\gamma_1(t_0)} \rightarrow (M_2)_{\gamma_2(t_0)}$ be any norm preserving isomorphism with $\phi(\gamma_1'(t_0)) = \gamma_2'(t_0)$. Then we can define

$$\phi_t: (M_1)_{\gamma_1(t)} \rightarrow (M_2)_{\gamma_2(t)}$$

by parallel translating a vector in $(M_1)_{\gamma_1(t)}$ along γ_1 to $\gamma_1(t_0)$, applying ϕ , and then parallel translating along γ_2 to $(M_2)_{\gamma_2(t)}$. We then define $\Phi(X)$ by

$$\Phi(X)(t) = \phi_t(X(t)).$$

We can also describe $\Phi(X)$ as follows. Let Y_1, \dots, Y_n be parallel, everywhere orthonormal vector fields along γ_1 with $Y_1(t_0) = \gamma_1'(t_0)$, and let Z_1, \dots, Z_n be

parallel, everywhere orthonormal vector fields along γ_2 with $Z_1(t_0) = \gamma_2'(t_0)$.
If

$$X(t) = \sum_{i=1}^n f_i(t) Y_i(t)$$

for certain functions $f_i: [a, b] \rightarrow \mathbb{R}$, then

$$\Phi(X)(t) = \sum_{i=1}^n f_i(t) Z_i(t).$$

This shows that $\Phi(X)$ is C^∞ everywhere that X is, and that

$$\langle X(t), \gamma_1'(t) \rangle = f_1(t) = \langle \Phi(X)(t), \gamma_2'(t) \rangle$$

$$\|X(t)\|^2 = \sum_{i=1}^n [f_i(t)]^2 = \|\Phi(X)(t)\|^2$$

$$\left\| \frac{DX}{dt}(t) \right\|^2 = \sum_{i=1}^n [f_i'(t)]^2 = \left\| \frac{D\Phi(X)}{dt}(t) \right\|^2. \quad \spadesuit$$

In our first generalization of Bonnet's Theorem, we will consider the index of a geodesic, instead of the number of conjugate points it contains. Recall (page 223) that the index of γ is > 0 if and only if there is some $W \in \Omega_\gamma$ with $E_{**}(W, W) < 0$.

19. THEOREM. Let M_1 and M_2 be two manifolds of the same dimension n , and let $\gamma_i: [a, b] \rightarrow M_i$ be geodesics parameterized by arclength. For each $t \in [a, b]$, suppose that for all 2-dimensional $P_i \subset (M_i)_{\gamma_i(t)}$, the curvatures K_i satisfy

$$K_1(P_1) \leq K_2(P_2).$$

Then we have

$$\text{index } \gamma_1 \leq \text{index } \gamma_2.$$

In particular, if $E_{**}(W_1, W_1) < 0$ for some $W_1 \in \Omega_{\gamma_1}$, then also $E_{**}(W_2, W_2) < 0$ for some $W_2 \in \Omega_{\gamma_2}$.

PROOF. Let W be a piecewise C^∞ vector field on γ_1 , and let Φ be the map in Lemma 18. The second variation formula shows that

$$\begin{aligned} (1) \quad E_{**}(W, W) = & - \int_a^b \langle R(W(t), V(t))V(t), W(t) \rangle dt \\ & - \int_a^b \left\langle W(t), \frac{D^2 W}{dt^2}(t) \right\rangle dt - \sum_{i=0}^N \left\langle W(t_i), \Delta_{t_i} \frac{DW}{dt} \right\rangle. \end{aligned}$$

Now we also have

$$\frac{d}{dt} \left\langle W(t), \frac{DW}{dt}(t) \right\rangle = \left\langle \frac{DW}{dt}(t), \frac{DW}{dt}(t) \right\rangle + \left\langle W(t), \frac{D^2W}{dt^2}(t) \right\rangle.$$

Integrating this equation between t_{i-1} and t_i for each i , and adding the results, we obtain

$$-\sum_{i=0}^N \left\langle W(t_i), \Delta_{t_i} \frac{DW}{dt_i} \right\rangle = \int_a^b \left\langle \frac{DW}{dt}(t), \frac{DW}{dt}(t) \right\rangle dt + \int_a^b \left\langle W(t), \frac{D^2W}{dt^2}(t) \right\rangle dt.$$

So equation (1) can be written

$$E_{**}(W, W) = \int_a^b \left\{ \left\langle \frac{DW}{dt}(t), \frac{DW}{dt}(t) \right\rangle - \langle R(W(t), V(t))V(t), W(t) \rangle \right\} dt.$$

From the properties of the map Φ , and the hypotheses on K , we see that

$$E_{**}(W, W) \geq E_{**}(\Phi(W), \Phi(W)).$$

So, if $\mathcal{V} \subset \Omega_{\gamma_1}$ is a subspace on which E_{**} is negative definite, then $\Phi(\mathcal{V}) \subset \Omega_{\gamma_2}$ is a subspace of the same dimension on which E_{**} is again negative definite. Thus the index of γ_2 is certainly at least as large as the index of γ_1 . ♦

20. COROLLARY (THE MORSE-SCHOENBERG COMPARISON THEOREM). Let M be a Riemannian manifold of dimension n , and let $\gamma: [0, L] \rightarrow M$ be a geodesic parameterized by arclength. Let $r > 0$ be a constant.

(1) If $K(P) \leq 1/r^2$ for all $P \in M_{\gamma(t)}$, and γ has length $L < \pi r$, then the index of γ is 0, and γ contains no conjugate point. [Note that Proposition 11 is a special case.]

(2) If $K(P) \geq 1/r^2$ for all $P \in M_{\gamma(t)}$, and γ has length $L > \pi r$, then there is a point $\tau \in (0, L)$ conjugate to 0, and γ is not of minimal length.

PROOF. (1) We apply the Theorem with $M_1 = M$ and $M_2 = n$ -sphere $S^n(r)$ of radius r , choosing γ_1 to be γ , and $\gamma_2: [0, L] \rightarrow S^n(r)$ to be any geodesic parameterized by arclength. We find that

$$\text{index } \gamma \leq \text{index } \gamma_2.$$

Now the index of γ_2 is certainly zero, since γ_2 contains no conjugate points, and Proposition 9 applies (all we really need is the fact that $E_{**}(W, W) \geq 0$

for $W \in \Omega_{\gamma_2}$, which follows from Theorem 8). Consequently, index $\gamma = 0$. Theorem 6 implies that no number $\tau \in (0, L)$ is conjugate to 0 along γ . We can also conclude that no number $\tau \in (0, L]$ is conjugate to 0 along γ , by extending γ to $\bar{\gamma}: [0, L'] \rightarrow M$ with $L < L' < \pi r$, and applying the result to $\bar{\gamma}$.

(2) We apply the Theorem with $M_1 = S^n(r)$ and $M_2 = M$, this time choosing γ_2 to be γ . We obtain

$$\text{index } \gamma_1 \leq \text{index } \gamma.$$

But the index of γ_1 is at least 1, since γ_1 contains a conjugate point, and Theorem 6 applies. Consequently, index $\gamma \geq 1$. This shows that γ does contain a conjugate point $\tau \in (0, L]$ (Proposition 9 or Theorem 8 again). Applying this result to $\gamma|_{[0, L']}$, with $\pi r < L' < L$, we see that γ contains a conjugate value $\tau \in (0, L)$. ♦

For the case where $K \geq 1/r^2$, we can obtain a stronger result, involving the Ricci tensor Ric , introduced in Chapter 7.G.

21. THEOREM (MYERS). Let M be an n -dimensional Riemannian manifold, and $\gamma: [0, L] \rightarrow M$ a geodesic parameterized by arclength. Let $r > 0$ be a constant, and suppose that

$$-\text{Ric}(\gamma'(t), \gamma'(t)) \geq \frac{n-1}{r^2} \quad \text{for all } t,$$

and that γ has length $L > \pi r$. Then there is a point $\tau \in (0, L)$ conjugate to 0, and γ is not of minimal length.

PROOF. Choose parallel, everywhere orthonormal vector fields Y_1, \dots, Y_n along γ with $Y_1 = V$. Let $W_i(t) = (\sin \pi t/L) Y_i(t)$. Then

$$\begin{aligned} E_{**}(W_i, W_i) &= - \int_0^L \left\langle W_i, \frac{D^2 W_i}{dt^2} + R(W_i, V)V \right\rangle dt \\ &= \int_0^L \left(\sin \frac{\pi t}{L} \right)^2 \left[\frac{\pi^2}{L^2} - \langle R(Y_i(t), Y_1(t)) Y_1(t), Y_i(t) \rangle \right] dt. \end{aligned}$$

Summing for $i = 2, \dots, n$, we obtain

$$\sum_{i=2}^n E_{**}(W_i, W_i) = \int_0^L \left(\sin \frac{\pi t}{L} \right)^2 \left[\frac{(n-1)\pi^2}{L^2} + \text{Ric}(Y_1(t), Y_1(t)) \right] dt.$$

By hypothesis, the term in brackets is < 0 , so some $E_{**}(W_i, W_i)$ is < 0 . Thus γ is not of minimal length, and there is $\tau \in (0, L)$ conjugate to 0 (same reasoning as in Corollary 20). ♦

Remark: If $\gamma: [0, L] \rightarrow S^n(r)$ is a geodesic parameterized by arclength, and Y is any parallel vector field along γ which is perpendicular to γ , then $W(t) = (\sin \pi t/L)Y(t)$ satisfies $E_{**}(W, W) < 0$. The vector fields W_i in the above proof come from such vector fields W by means of the map Φ of Lemma 18. This may make the proof of Myers' theorem somewhat less mysterious.

The next result reproduces the reasoning in the third part of Bonnet's theorem, together with an observation of interest only in the higher dimensional case.

22. COROLLARY. Let M be a complete connected n -dimensional manifold with

$$-\text{Ric}(X, X) \geq \frac{n-1}{r^2}$$

for all unit vectors X , where $r > 0$ is a constant. (This hypothesis holds, in particular, if $K(P) \geq 1/r^2$ for all plane sections P .) Then M is actually compact, with diameter $\leq \pi r$. Moreover, the fundamental group of M is finite.

PROOF. The proof of the first part is exactly the same as in Bonnet's theorem. To prove that the fundamental group of M is finite, we simply consider the universal covering space $\pi: \tilde{M} \rightarrow M$ of the Riemannian manifold $(M, \langle \cdot, \cdot \rangle)$. Clearly $(\tilde{M}, \pi^*\langle \cdot, \cdot \rangle)$ is complete, and its Ricci curvature also satisfies $-\text{Ric}(X, X) \geq (n-1)/r^2$ for all unit vectors X . Therefore \tilde{M} is compact. ♦

Although Theorem 19 certainly generalizes Bonnet's theorem very nicely, we do lose some information in this approach. Roughly speaking, we have generalized to higher dimensions only the first part of the Sturm comparison theorem, telling us that our Jacobi field $\Phi(W)$ must vanish somewhere on (a, b) ; we have not generalized the second part by comparing $\|\Phi(W)\|$ with $\|W\|$ up to the first zero of $\Phi(W)$. Such information is provided by

23. THEOREM (THE RAUCH COMPARISON THEOREM). Let M_1 and M_2 be two manifolds of the same dimension n , and let $\gamma_i: [a, b] \rightarrow M_i$ be geodesics parameterized by arclength such that

- (1) no number $\tau \in (a, b]$ is a conjugate value of 0 along γ_1 in M_1 or along γ_2 in M_2 .

Let W_i be Jacobi fields along γ_i such that

- (2) $W_i(a) = 0$,

$$(3) \quad \left\| \frac{DW_1}{dt}(a) \right\| = \left\| \frac{DW_2}{dt}(a) \right\|,$$

(4) W_i is perpendicular to γ_i .

For all $t \in [a, b]$, suppose that for all 2-dimensional $P_i \subset (M_i)_{\gamma_i(t)}$, the curvatures K_i satisfy

$$(5) \quad K_1(P_1) \leq K_2(P_2).$$

Then

$$\|W_1(t)\| \geq \|W_2(t)\| \quad \text{for all } t \in [a, b].$$

PROOF. If $W_2 = 0$, the theorem is trivial. If W_2 is not the 0 vector field, then $W_2(t) \neq 0$ for all $t \in (a, b)$, since γ_2 has no conjugate points. Naturally, $W_1(t)$ is also non-zero for all $t \in (a, b)$. It obviously suffices to prove that

$$(1) \quad \lim_{t \rightarrow 0} \frac{\langle W_1, W_1 \rangle(t)}{\langle W_2, W_2 \rangle(t)} = 1$$

$$(2) \quad \frac{d}{dt} \frac{\langle W_1, W_1 \rangle(t)}{\langle W_2, W_2 \rangle(t)} \geq 0 \quad \text{for } t \in (a, b).$$

To prove (1) we note that

$$\begin{aligned} \lim_{t \rightarrow 0} \frac{\langle W_1, W_1 \rangle(t)}{\langle W_2, W_2 \rangle(t)} &= \lim_{t \rightarrow 0} \frac{\left\langle W_1, \frac{DW_1}{dt} \right\rangle(t)}{\left\langle W_2, \frac{DW_2}{dt} \right\rangle(t)} && \text{by L'Hôpital's Rule} \\ &= \lim_{t \rightarrow 0} \frac{\left\langle \frac{DW_1}{dt}, \frac{DW_1}{dt} \right\rangle(t) + \left\langle W_1, \frac{D^2 W_1}{dt^2} \right\rangle(t)}{\left\langle \frac{DW_2}{dt}, \frac{DW_2}{dt} \right\rangle(t) + \left\langle W_2, \frac{D^2 W_2}{dt^2} \right\rangle(t)} \\ &&& \text{by L'Hôpital's Rule} \\ &= 1, && \text{by hypothesis (3).} \end{aligned}$$

(Note that the first use of L'Hôpital's Rule is a genuine one, necessitated by the fact that we need to look at $\langle W_i, W_i \rangle$, rather than $\|W_i\|$. The second use, however, represents the same trivial case which occurs in the Sturm comparison theorem.)

Equation (2) is equivalent to

$$\langle W_2, W_2 \rangle \cdot \left\langle W_1, \frac{DW_1}{dt} \right\rangle \geq \langle W_1, W_1 \rangle \cdot \left\langle W_2, \frac{DW_2}{dt} \right\rangle,$$

so for each $t_0 \in (a, b)$ it suffices to show that

$$(2') \quad \left\langle W_1, \frac{DW_1}{dt} \right\rangle(t_0) \geq c^2 \left\langle W_2, \frac{DW_2}{dt} \right\rangle(t_0),$$

where $c = \|W_1(t_0)\|/\|W_2(t_0)\|$.

But, since the W_i are Jacobi fields, and $W_i(a) = 0$, the second variation formula shows that

$$\left\langle W_i, \frac{DW_i}{dt} \right\rangle(t_0) = E_{**}(\tilde{W}_i, \tilde{W}_i),$$

where $\tilde{W}_i = W_i|_{[a, t_0]}$.

Therefore, we just have to prove that

$$(2'') \quad E_{**}(\tilde{W}_1, \tilde{W}_1) \geq c^2 E_{**}(\tilde{W}_2, \tilde{W}_2).$$

Consider the map Φ of Lemma 18, constructed for the geodesics $\gamma_i|_{[0, t_0]}$. Since $W_i(t_0)$ are both non-zero, and orthogonal to γ_i , we can obviously define Φ so that

$$(3) \quad \Phi(\tilde{W}_1)(t_0) = c \tilde{W}_2(t_0).$$

In the first part of the proof of Theorem 19 we showed that

$$(4) \quad E_{**}(\tilde{W}_1, \tilde{W}_1) \geq E_{**}(\Phi(\tilde{W}_1), \Phi(\tilde{W}_1)).$$

On the other hand, we have $\tilde{W}_2(a) = \Phi(\tilde{W}_1)(a) = 0$ by hypothesis (2) and the norm preserving property of Φ , while $c\tilde{W}_2(t_0) = \Phi(\tilde{W}_1)(t_0)$ by (3). So Corollary 10 yields

$$(5) \quad \begin{aligned} E_{**}(\Phi(\tilde{W}_1), \Phi(\tilde{W}_1)) &\geq E_{**}(c\tilde{W}_2, c\tilde{W}_2) \\ &= c^2 E_{**}(\tilde{W}_2, \tilde{W}_2). \end{aligned}$$

Equations (4) and (5) together give the required equation (2''). ♦

Unless you have become totally lost in these generalities, it should be clear that Theorem 23 can also be used to prove the results of Corollary 20. Rauch actually used his comparison theorem to prove a much more striking result, concerning “ δ -pinched” manifolds. These are Riemannian manifolds satisfying

$$\delta A \leq K(P) \leq A$$

for all 2-dimensional subspaces $P \subset M_p$ at all points $p \in M$; here A is a constant, which we can assume is 1 if we are willing to multiply the metric $\langle \cdot, \cdot \rangle$ by a constant. Rauch proved that if M is complete and simply-connected, and δ -pinched for a certain $\delta \sim .74$, then M is homeomorphic to a sphere. Improvements by Berger and Klingenberg have established the

SPHERE THEOREM. Let M be a complete, simply-connected Riemannian manifold of dimension n whose sectional curvatures $K(P)$ satisfy

$$\delta \leq K(P) \leq 1$$

for some constant $\delta > 1/4$. Then M is homeomorphic to S^n .

It is known that for even n this result breaks down if we allow $\delta = 1/4$. We will not go into the rather detailed proofs of this and related recent results, which together would make up a good sized monograph. A large selection is coherently presented in Gromoll, Klingenberg, Meyer [1], and references to a few more will be found in the bibliography.

One of the most striking recent results completely clarifies the requirement in many of our theorems that the sectional curvatures should not only be positive, but also bounded away from 0. Naturally, this latter condition can fail only when the manifold M is not compact; but in this case the structure of M is completely determined:

THEOREM (GROMOLL-MEYER). If M is a connected, complete, non-compact n -dimensional manifold with all sectional curvatures positive, then M is diffeomorphic to \mathbb{R}^n .

Although we must omit the proofs of these theorems, we can prove an older and easier, but still very striking, result about the topology of manifolds whose sectional curvatures are all positive. We begin with a lemma that will also be used later on.

24. LEMMA (SYNGE). Let M be an orientable even-dimensional Riemannian manifold with all sectional curvatures positive. Let $\gamma: [a, b] \rightarrow M$ be a geodesic which is closed [that is, $\gamma(a) = \gamma(b)$ and $\gamma'(a) = \gamma'(b)$]. Then there is a variation $\alpha: (-\varepsilon, \varepsilon) \times [a, b] \rightarrow M$ of γ such that all curves $\bar{\alpha}(u)$ are closed curves with length $\bar{\alpha}(u) < \text{length } \gamma$ for $u \neq 0$.

PROOF. Let $\mathcal{V} = \gamma'(0)^\perp \subset M_p$ be the $(n-1)$ -dimensional subspace of all $X_p \in M_p$ which are perpendicular to $\gamma'(0)$. Define $\phi: \mathcal{V} \rightarrow \mathcal{V}$ to be the result of parallel translation around γ . Then ϕ is a norm preserving linear transformation, with matrix A satisfying $AA^t = 1$ (where A^t is the transpose of A), so $\det \phi = \pm 1$. Moreover, since M is orientable, it is easy to see that $\phi: \mathcal{V} \rightarrow \mathcal{V}$ must be orientation preserving, so that $\det \phi = +1$. Since the dimension of \mathcal{V} is odd, the characteristic polynomial of ϕ has at least one real root, so ϕ has a real eigenvalue, which clearly must be ± 1 . Moreover, the complex eigenvalues occur in conjugate pairs $\lambda, \bar{\lambda}$ with $\lambda\bar{\lambda} > 0$. The number of real eigenvalues ± 1 is therefore odd, and their product is positive, so at least one must be $+1$. Consequently, ϕ leaves some vector field fixed: $\phi(X_p) = X_p$ for some $X_p \in \mathcal{V}$. This means that parallel translation of X_p around γ produces a vector field X along γ with $X(a) = X(b)$.

Let $\alpha: (-\varepsilon, \varepsilon) \times [a, b] \rightarrow M$ be a variation of γ with variation vector field $\partial\alpha/\partial u(0, t) = X(t)$. Since $X(a) = X(b)$, we can clearly choose α so that $\alpha(u, a) = \alpha(u, b)$ for all u , which means that each $\bar{\alpha}(u)$ is a closed curve. Applying the second variation formula, and remembering that $DX/dt = 0$, we find that

$$E_{**}(X, X) = - \int_a^b \langle X(t), R(X(t), V(t))V(t) \rangle dt$$

< 0 , by the hypothesis on sectional curvatures.

This means that for sufficiently small $u \neq 0$, the curves $\bar{\alpha}(u)$ have smaller energy than γ . ♦

With this Lemma we can easily prove the following result, provided that we accept an “intuitively obvious” fact, whose proof will come soon afterwards. We will temporarily use the term “closed path” for a continuous path $c: [0, 1] \rightarrow M$ with $c(0) = c(1)$; the term “smooth closed path” will be used for a smooth path $c: [0, 1] \rightarrow M$ with $c(0) = c(1)$ and $c'(0) = c'(1)$.

25. THEOREM (SYNGE). Let M be a compact, connected, orientable, even-dimensional Riemannian manifold with all sectional curvatures positive. Then M is simply-connected.

PROOF. Pick a point $p \in M$ and suppose that $\pi_1(M, p) \neq 0$. Let $c: [0, 1] \rightarrow M$ be a closed path with $c(0) = c(1) = p$, representing a non-zero element of $\pi_1(M, p)$. We say that a closed path γ is in the same **free homotopy class** as c if c and γ are homotopic, considered simply as maps from S^1 into M .

CLAIM. There is a closed curve $\gamma: [0, 1] \rightarrow M$ in the same free homotopy class as c which has smaller length than any other closed curve in this free homotopy class.

If we accept this claim, then it is clear that γ must be a smooth closed geodesic. For every sufficiently small segment of γ must coincide with a geodesic, since geodesics are the smallest paths between sufficiently close points.

The proof is now immediate, for we obtain a contradiction by applying Synge's Lemma to γ . ♦

Before we proceed with the proof of the Claim, we add a few remarks. The hypothesis that M is *compact* can be replaced by the hypothesis that M is complete and has sectional curvatures bounded away from 0, by Corollary 22. In fact, the Theorem of Gromoll-Meyer (page 239) shows that compactness can be replaced by completeness alone. The hypothesis that M is *orientable* is clearly necessary, as shown by the projective spaces P_n with n even. However, one can easily show (Problem 3) that if M is not orientable, then $\pi_1(M) \approx \mathbb{Z}_2$. The necessity of assuming that M is *even-dimensional* is shown by the projective spaces P_n with n odd. Without this assumption we must content ourselves with showing (Problem 3) that if M is a compact, connected odd-dimensional manifold with all sectional curvatures positive, then M is orientable.

We will now give two different proofs of the Claim. The first of these, the official proof, uses a few facts about covering spaces, and is generally considered to be quite elegant. The second proof is a more typical example of the sort of "direct methods" which one can sometimes use in order to establish that solutions to calculus of variation problems actually exist, instead of merely finding conditions on the presumed solution; it is similar to arguments first used by Hilbert for that sort of question (and similar arguments could be used to give an alternative demonstration that a minimal geodesic exists between any two points in a complete manifold). That, I feel, is one good reason for including it;

it also turns out that this proof is no harder than the first proof if the details are handled intelligently.

26. PROPOSITION. If $(M, \langle \cdot, \cdot \rangle)$ is a non-simply-connected compact Riemannian manifold, then every free homotopy class contains a curve of minimum length.

FIRST PROOF. Let \tilde{M} be the universal covering space of M and $\pi: \tilde{M} \rightarrow M$ the projection; the complete Riemannian metric $\pi^*\langle \cdot, \cdot \rangle$ on \tilde{M} gives an ordinary metric d on \tilde{M} . Recall that a homeomorphism $\phi: \tilde{M} \rightarrow \tilde{M}$ with $\pi \circ \phi = \pi$ is called a “covering transformation” or “deck transformation” of \tilde{M} . The set \mathcal{D} of all deck transformations is in one-one correspondence with $\pi_1(M, p)$ for any $p \in M$, and d is invariant under the action of \mathcal{D} .

Given a closed path $c: [0, 1] \rightarrow M$, let $\tilde{c}: [0, 1] \rightarrow \tilde{M}$ be a lifting, starting at some point $q \in \pi^{-1}(c(0))$. Then

$$\tilde{c}(1) = \delta(q) = \delta(\tilde{c}(0)) \quad \text{for a unique } \delta \in \mathcal{D}.$$

To see how this δ depends on the choice of $q \in \pi^{-1}(c(0))$, we note that any other point $q \in \pi^{-1}(c(0))$ is $\phi(q)$ for some $\phi \in \mathcal{D}$, and that the lifting \tilde{c} of c starting at $\phi(q)$ is just $\phi \circ \tilde{c}$. This means that

$$\tilde{c}(1) = \phi(\tilde{c}(1)) = \phi(\delta(q)) = \phi \circ \delta \circ \phi^{-1}(\phi(q)) = \phi \circ \delta \circ \phi^{-1}(\tilde{c}(0)).$$

Thus:

- (1) The conjugacy class $\{\phi\delta\phi^{-1} : \phi \in \mathcal{D}\}$ does not depend on the choice of $q \in \pi^{-1}(c(0))$.

We also claim:

- (2) If $c_1: [0, 1] \rightarrow M$ is freely homotopic to c , then it determines the same conjugacy class.

For, we have a map $H: I \times I \rightarrow M$ with

$$\begin{aligned} H(t, 0) &= c(t) \\ H(t, 1) &= c_1(t) \\ H(0, s) &= H(1, s). \end{aligned}$$

Let \tilde{H} be a lifting of H , and define $\tilde{c}(t) = \tilde{H}(t, 0)$ and $\tilde{c}_1(t) = \tilde{H}(t, 1)$. We have $\tilde{H}(1, s) = \delta(s)(\tilde{H}(0, s))$ for some $\delta(s)$, and all $\delta(s)$ must be the same δ , by

continuity. Thus both c and c_1 determine the same conjugacy class $\{\phi\delta\phi^{-1} : \phi \in \mathcal{D}\}$.

Finally, we claim:

- (3) If $\gamma_1, \gamma_2: [0, 1] \rightarrow \tilde{M}$ are paths with $\gamma_i(1) = \delta(\gamma_i(0))$, then $\pi \circ \gamma_1$ is freely homotopic to $\pi \circ \gamma_2$.

To prove this, we let $\gamma: [0, 1] \rightarrow \tilde{M}$ be a path from $\gamma_1(0)$ to $\gamma_2(0)$. Then $\delta \circ \gamma$ is a path from $\gamma_1(1)$ to $\gamma_2(1)$. So we can define a continuous map $H: \partial([0, 1] \times [0, 1]) \rightarrow \tilde{M}$ as follows:

Since \tilde{M} is simply-connected, we can extend this to a map $H: [0, 1] \times [0, 1] \rightarrow \tilde{M}$. Then $\pi \circ H: [0, 1] \times [0, 1] \rightarrow M$ satisfies

$$\pi \circ H(0, s) = \pi \circ H(1, s) \quad \text{for all } s \in [0, 1].$$

So $\pi \circ \gamma_1$ is freely homotopic to $\pi \circ \gamma_2$.

Now let $\{\phi\delta\phi^{-1} : \phi \in \mathcal{D}\}$ be the conjugacy class corresponding to our given free homotopy class, and define $h_\delta: \tilde{M} \rightarrow \tilde{M}$ by

$$h_\delta(q) = \inf\{d(q, \phi\delta\phi^{-1}(q)) : \phi \in \mathcal{D}\};$$

this is well-defined, since it clearly depends only on the conjugacy class of δ . Notice that for each q there is some ϕ (depending on q) such that

$$h_\delta(q) = d(q, \phi\delta\phi^{-1}(q));$$

this follows from the fact that \mathcal{D} acts discretely. It is also clear that h_δ is invariant under the action of \mathcal{D} . It follows that h_δ takes on its minimum on \tilde{M} ; for there is a compact set $K \subset \tilde{M}$ with $\pi(K) = M$, and consequently $\mathcal{D}(K) = \tilde{M}$, which means that the minimum of h_δ on K is also the minimum on all of \tilde{M} . Say that h_δ takes on its minimum at $q_0 \in \tilde{M}$, and that

$$h_\delta(q_0) = d(q_0, \phi_0\delta\phi_0^{-1}(q_0)).$$

Let γ be a minimal geodesic in \tilde{M} from q_0 to $\phi_0\delta\phi_0^{-1}(q_0)$, with length $\gamma = h_\delta(q_0)$. Then also

$$\text{length } \pi \circ \gamma = h_\delta(q_0).$$

The curve $\pi \circ \gamma$ is in the given free homotopy class, by (3). If c is any other curve in the free homotopy class, and \tilde{c} is any lifting, starting at some point q , then $\tilde{c}(1)$ is $\psi\delta\psi^{-1}(q)$ for some $\psi \in \mathcal{D}$, and consequently

$$\begin{aligned} \text{length } c &= \text{length } \tilde{c} \geq d(q, \psi\delta\psi^{-1}(q)) \\ &\geq h_\delta(q) \geq h_\delta(q_0) = \text{length } \pi \circ \gamma. \end{aligned}$$

SECOND PROOF. Since M is compact, there is a finite open cover U_1, \dots, U_r of M by geodesically convex sets. By the Lebesgue covering lemma, there is $\varepsilon > 0$ such that any set A with diameter $< \varepsilon$ lies entirely in some U_α .

A closed curve c in M will be called **special** if there is a sequence $p_0, p_1, \dots, p_N = p_0$ of points in M such that

- (i) for each j , the points p_{j-1}, p_j both lie in some U_α
- (ii) c is the union of minimal geodesics c_j joining p_{j-1} to p_j .

Given an arbitrary closed curve $c: [0, 1] \rightarrow M$, there is always a special closed curve \bar{c} in the same free homotopy class as c , with length $l(\bar{c}) \leq l(c)$. To prove this, we consider the cover $\{c^{-1}(U_\alpha)\}$ of $[0, 1]$. The Lebesgue covering lemma implies the existence of a sequence $0 = t_0 \leq \dots \leq t_N = 1$ such that each $[t_{j-1}, t_j]$ is contained in some $c^{-1}(U_\alpha)$; this means that the restriction $c|_{[t_{j-1}, t_j]}$ is contained in U_α . We can then let \bar{c} be the union of the minimal geodesics

in U_α joining $p_{j-1} = c(t_{j-1})$ to $p_j = c(t_j)$. It is clear that $l(\bar{c}) \leq l(c)$. Since each U_α is geodesically convex, it is also clear that \bar{c} is homotopic to c .

Now consider a particular free homotopy class of closed curves. The set of lengths of all closed curves in this free homotopy class has a greatest lower bound $l \geq 0$. Our aim is to find a closed curve c in this free homotopy class

with length $l(c) = l$. We can certainly find a sequence $c^{(i)}$ of curves in this free homotopy class with

$$(1) \quad l(c^{(i)}) \rightarrow l;$$

we might as well assume that we also have

$$(2) \quad l(c^{(i)}) < 2l \quad \text{for all } i.$$

Finally, we can clearly assume that

$$(3) \quad \text{each } c^{(i)} \text{ is special.}$$

Now in the definition of a special closed curve, no bound was placed on the number N of division points involved. However, if the N for any of our curves $c^{(i)}$ is sufficiently large, then we can always find a new $c^{(i)}$, in the same homotopy class, and with no larger length, but with a smaller N . To see why this is so, consider the $[N/2]$ curves

$$\gamma_1 = c^{(i)} \text{ from } p_0 \text{ to } p_2$$

$$\gamma_2 = c^{(i)} \text{ from } p_2 \text{ to } p_4$$

$$\vdots$$

If any one of these curves has length $< \varepsilon$, then it lies entirely in some U_α , so we can replace it by a single minimal geodesic, thereby reducing N . Clearly:

if $l(c) < \left[\frac{N}{2}\right] \varepsilon$, then some γ_v has length $< \varepsilon$, so N can be reduced.

Using (2), we find:

if $2l < \left[\frac{N}{2}\right] \varepsilon$, then some γ_v has length $< \varepsilon$, so N can be reduced.

Phrasing this slightly differently, we have:

if $N > 2\left(\frac{2l}{\varepsilon} + 1\right)$, then N can be reduced.

Since this is true for all curves $c^{(i)}$, we can assume that all curves $c^{(i)}$ have $N \leq 2(2l/\varepsilon + 1)$. Since extra points can always be stuck in, we can actually assume that

$$(4) \quad \text{each } c^{(i)} \text{ is special with } N = N_0 = \left\lceil 2\left(\frac{2l}{\varepsilon} + 1\right) \right\rceil.$$

The remainder of the proof is now very simple. Let

$$p_0^{(i)}, p_1^{(i)}, \dots, p_{N_0}^{(i)} = p_0^{(i)}$$

be the points determining $c^{(i)}$. Since M is compact, we may assume, by taking subsequences, that for each $j = 0, \dots, N_0$ we have

$$\lim_{i \rightarrow \infty} p_j^{(i)} = p_j \in M.$$

Joining the pairs p_{j-1}, p_j by minimal geodesics, we obtain a closed curve c . Clearly

$$\begin{aligned} l(c) &= \sum_{j=1}^{N_0} d(p_{j-1}, p_j) = \lim_{i \rightarrow \infty} \sum_{j=1}^{N_0} d(p_{j-1}^{(i)}, p_j^{(i)}) \\ &= \lim_{i \rightarrow \infty} l(c^{(i)}) = l. \end{aligned}$$

To prove that c is in the same homotopy class as the $c^{(i)}$, we will carry out the construction a wee bit more carefully. We assume first that the original choice of the U_α was made so that there are geodesically convex sets $W_\alpha \supset \overline{U_\alpha}$. Now consider a fixed j . For each i , the points $p_{j-1}^{(i)}, p_j^{(i)}$ both lie in some U_α . Since there are only finitely many U_α , one of them, $U_{\alpha(j)}$ say, must contain both $p_{j-1}^{(i)}$ and $p_j^{(i)}$ for infinitely many i . By taking a subsequence, we can assume that all $p_{j-1}^{(i)}$ and $p_j^{(i)}$ are in $U_{\alpha(j)}$. There are only finitely many j to consider, so by taking subsequences we may assume that

$$\text{all } p_{j-1}^{(i)} \text{ and } p_j^{(i)} \text{ are in some } U_{\alpha(j)}, \quad j = 1, \dots, N_0.$$

This clearly implies that

$$p_{j-1} \text{ and } p_j \text{ are in } \overline{U_{\alpha(j)}} \subset W_{\alpha(j)} \quad j = 1, \dots, N_0.$$

Using geodesic convexity of the W_α , it is easy to see that c is homotopic to any $c^{(i)}$. ♦

[We now reinstate the normal terminology, and use “closed curves” for curves $c: [0, 1] \rightarrow M$ with $c(0) = c(1)$ and $c'(0) = c'(1)$.]

We will end this chapter by considering a natural problem of deceptively simple appearance, which to this day remains unsolved. This problem will lead us to the study of “cut points”, which are related to, but still quite different from,

the conjugate points which we have been considering all along. We have seen (Corollary 22) that a complete connected manifold with all sectional curvatures $\geq 1/r^2$ has diameter $\leq \pi r$. It is natural to assume that in a similar way, a complete manifold with small sectional curvatures should have large diameter—if all $K(P) \leq 1/r^2$, then M should have diameter $\geq \pi r$. A counterexample to this conjecture is provided by projective space P_n , with constant curvature $= 1$, and diameter only $\pi/2$. And clearly, the larger the fundamental group, the smaller we might expect the diameter to be. An extreme case is represented by the torus, with infinite fundamental group. If we give the torus a flat metric, then $K \leq 1/r^2$ for every $r > 0$; on the other hand, we can also arrange for the diameter to be as small as we like. With the added hypothesis of simple connectivity, the conjecture still seems reasonable:

A complete, simply-connected, manifold with all $K(P) \leq 1/r^2$ should have diameter $\geq \pi r$.

One might expect to construct a proof of this conjecture along the following lines. We choose two points $p, q \in M$ at maximum distance apart, and consider a minimal geodesic $\gamma: [0, L] \rightarrow M$ which joins them. If γ has length $L < \pi r$, then we extend γ to $\bar{\gamma}: [0, L'] \rightarrow M$ with $L < L' < \pi r$, and the extended geodesic $\bar{\gamma}$ has no conjugate points, since $K(P) \leq 1/r^2$. Thus $\bar{\gamma}$ is a local minimum for length. Since p and q were already at the maximum distance apart, we might expect a contradiction to emerge from this construction. Of course, it can't, because we haven't used simple connectivity anywhere. The case of an ellipsoid shows where the problem lies. If γ is a geodesic joining the

two furthest points p and q , and extending somewhat further beyond q to q' , then γ is certainly not the shortest path between p and q' . But it *is* the shortest path among nearby paths, since γ contains no conjugate points. It seems clear that there is little hope of attacking this problem if we consider only conjugate points, since they only give us information about the *local* length minimizing property of geodesics, and our problem is a global one.

The notion of a cut point was made precisely in order to deal with global minimizing properties of geodesics. For simplicity, we will deal only with the case of a complete Riemannian manifold $(M, \langle \cdot, \cdot \rangle)$, and we will let $d: M \times M \rightarrow \mathbb{R}$ be the ordinary metric on M determined by the Riemannian metric $\langle \cdot, \cdot \rangle$. Suppose we have a geodesic $\gamma: [0, \infty) \rightarrow M$ starting at a point $p = \gamma(0)$ in M , and parameterized by arclength. Consider the set

$$\begin{aligned} A &= \{t > 0 : d(p, \gamma(t)) = t\} \\ &= \{t > 0 : \gamma|_{[0, t]} \text{ is a minimal geodesic}\}. \end{aligned}$$

It is clear that either $A = (0, \infty)$ or else A is a set of the form $(0, a]$. If $A = (0, a]$, we say that $\gamma(a)$ is the **cut point** of p along the geodesic γ , while if $A = (0, \infty)$, we say that p has no cut point along γ . The **cut locus** $C(p) \subset M$ of p is then defined to be the set of all points which are cut points of p along some arclength parameterized geodesic starting from p . We also define the **cut locus** $\tilde{C}(p)$ of p in M_p to be the set of all vectors $aX \in M_p$ for which X is a unit vector and $\exp aX$ is the cut point of p along the geodesic $\gamma_X(t) = \exp tX$. Thus $C(p) = \exp(\tilde{C}(p))$. On the other hand, we define the **conjugate locus** of p in M_p to be the set of all vectors $aX \in M_p$ for which X is a unit vector and a is the first conjugate value of 0 along γ_X . A particular ray in M_p may contain neither a point of the conjugate locus nor a point of the cut locus. But if it contains a point aX of the conjugate locus, then by Theorem 6 it must also contain a point $a'X$ of the cut locus, with $a' \leq a$; briefly expressed, the cut point comes before or at the first conjugate point.

Notice that if M is compact, then there is certainly a cut point along every geodesic; but there may not be any conjugate points, as is shown by the case of a compact surface of everywhere negative curvature.

Suppose now that M is a simply-connected compact Riemannian manifold with all sectional curvatures $K(P) \leq 1/r^2$. If there is any point $p \in M$ for which the cut locus $\tilde{C}(p)$ in M_p and the conjugate locus in M_p intersect, say at a vector $v_p \in M_p$, then the diameter of M_p must be $\geq \pi r$. For, on the one hand, the geodesic $t \mapsto \exp tv_p$ is a minimal geodesic from p to $q = \exp v_p$, so $d(p, q) = \|v_p\|$; and on the other hand, the point q is conjugate to p , so $\|v_p\| \geq \pi r$ by Corollary 20.

Notice that the point q need not necessarily be the point furthest from p . For example, in the figure at the top of the next page, demonstrating the case of the ellipsoid on page 221, the cut locus of p is the portion of the geodesic from A to p' to C ; so q is A or C .

Unfortunately, it is not known whether such a point p always exists on a simply-connected compact manifold M . There are only partial results in this direction, and before giving one of them we will need to develop some basic properties of cut points.

One simple remark is sufficiently important to list as a separate result. Suppose that $\gamma: [0, \infty) \rightarrow M$ is a geodesic and $q = \gamma(t_0)$ comes *strictly before* the first cut point. Then, of course, any other geodesic ω from $p = \gamma(0)$ to q must have length $\omega \geq t_0$. But actually the strict inequality holds:

27. PROPOSITION. Let M be complete, let $\gamma: [0, \infty) \rightarrow M$ be a geodesic parameterized by arclength, and let $\gamma(t_0)$ come strictly before the cut point $\gamma(a)$ (if there is one). Then any other geodesic ω from $p = \gamma(0)$ to $q = \gamma(t_0)$ has length $\omega > t_0$.

PROOF. Suppose length $\omega = t_0 = \text{length } \gamma|[0, t_0]$. Choose $\varepsilon > 0$ so that $\gamma|[0, t_0 + \varepsilon]$ is also minimal. Then $\gamma|[0, t_0 + \varepsilon]$ has the same length as ω followed by $\gamma|[t_0, t_0 + \varepsilon]$. But this compound curve has a corner, so it can be made

shorter, and therefore $\gamma|[0, t_0 + \varepsilon]$ is *not* of minimal length, a contradiction. ♦

Notice that this argument does not work if $\gamma(t_0)$ is the cut point. In fact,

28. PROPOSITION. Let M be complete and let $\gamma: [0, \infty) \rightarrow M$ be a geodesic parameterized by arclength, with cut point $\gamma(a)$. Then at least one of the following holds:

- (1) The number a is the first conjugate value of 0 along γ .
- (2) There are at least two minimal geodesics from $p = \gamma(0)$ to $q = \gamma(a)$.

PROOF. Choose a sequence $a_1 > a_2 > a_3 > \dots$ with

$$(1) \quad \lim_{i \rightarrow \infty} a_i = a.$$

Let $b_i = d(p, \gamma(a_i)) < a_i$ and let X_i be unit vectors in M_p such that

$$t \mapsto \exp tX_i \quad 0 \leq t \leq b_i$$

is a minimal geodesic from p to $\gamma(a_i)$. Naturally, all X_i are distinct from $X = \gamma'(0)$. Then we also have

$$(2) \quad \lim_{i \rightarrow \infty} b_i = \lim_{i \rightarrow \infty} d(p, \gamma(a_i)) = d(p, \gamma(a)) = a.$$

Equation (2) shows that the vectors $b_i X_i$ are contained in a compact subset of M_p . Choosing a subsequence if necessary, we can assume that

$$(3) \quad \lim_{i \rightarrow \infty} b_i X_i = aY, \quad Y \in M_p \text{ a unit vector.}$$

Since $\exp aY = \lim_{i \rightarrow \infty} \exp b_i X_i = \lim_{i \rightarrow \infty} \gamma(a_i) = \gamma(a)$, the geodesic

$$t \mapsto \exp tY \quad 0 \leq t \leq a$$

is a minimal geodesic from p to q . So if $X \neq Y$ we have situation (2). To complete the proof we just have to show that if $X = Y$, then the number a must be conjugate to 0.

Now if $X = Y$, then $\lim_{i \rightarrow \infty} b_i X_i = aY = aX = \lim_{i \rightarrow \infty} a_i X$. But

$$(4) \quad \exp(b_i X_i) = \gamma(a_i) = \exp(a_i X).$$

So every neighborhood of aX contains infinitely many pairs $b_i X_i, a_i X$ on which \exp has the same value; and these vectors $a_i X$ and $b_i X_i$ are definitely distinct

(since the X_i are different from X , or, just as conclusively, since $b_i < a < a_i$). So aX must be a critical point of \exp . Thus Theorem 7 shows that a is a conjugate value of 0 along γ . ♦

Proposition 28 can be used to derive several other facts about cut points. First of all, we have

29. PROPOSITION. In a complete manifold M , if q is the cut point of p along a geodesic γ from p to q , then p is the cut point of q along the geodesic $\bar{\gamma}$ obtained by traversing γ in the opposite direction.

PROOF. The hypothesis implies that γ is a minimal geodesic from p to q . So $\bar{\gamma}$ is minimal from q to p ; consequently, the cut point of $\bar{\gamma}$, if there is one, occurs *past* or at p . Now γ must satisfy one of the two alternatives in Proposition 28.

- (1) If q is conjugate to p along γ , then of course p is conjugate to q along $\bar{\gamma}$. The cut point must then occur *before* or at p . So it must occur at p .
- (2) If there is another minimizing geodesic from q to p , then again p must be the cut point, since Proposition 27 shows that there cannot be another minimal geodesic to a point strictly before the cut point. ♦

Consider now the “sphere bundle” $S(M)$ of M , consisting of all unit tangent vectors at all points of M ; this is a submanifold of the tangent bundle TM . Let $\mathbb{R}^* = \mathbb{R} \cup \{\infty\}$ be the real numbers together with some other set “ ∞ ”. The ordering $<$ on \mathbb{R} can be extended to \mathbb{R}^* by defining $a < \infty$ for all $a \in \mathbb{R}$. We give \mathbb{R}^* the order topology (a basis consists of all sets of the form $(a, b) \subset \mathbb{R}$, together with all sets of the form $(a, \infty] = (a, \infty) \cup \{\infty\}$.) We now define a function $\mu: S(M) \rightarrow \mathbb{R}^*$ by

$$\mu(X) = \begin{cases} a > 0 & \text{if } aX \text{ is the cut point of } p \text{ along} \\ & \text{the geodesic } \gamma_X(t) = \exp tX \\ \infty & \text{if } \gamma_X \text{ has no cut point.} \end{cases}$$

30. THEOREM. If M is a complete manifold, then the function $\mu: S(M) \rightarrow \mathbb{R}^*$ is continuous.

PROOF. Let X_1, X_2, X_3, \dots be a sequence of unit vectors in $S(M)$ converging to a unit vector $X \in M_p$, and suppose that $a_i = \mu(X_i)$ did not converge to $a = \mu(X)$. Since the values of μ lie in the compact set $\{\alpha \in \mathbb{R}^* : \alpha \geq 0\}$, we can assume, by choosing a subsequence, that a_i converges to some $\alpha \in \mathbb{R}^*$ with $\alpha \neq a$. Suppose for the moment that α is in \mathbb{R} (and consequently all but finitely many a_i are in \mathbb{R}). Then $a_i X_i$ converges to αX . Now it is clear from the definition of μ that

$$d(p, \exp a_i X_i) = a_i.$$

So

$$\begin{aligned} d(p, \exp \alpha X) &= d(p, \lim_{i \rightarrow \infty} \exp a_i X_i) \\ &= \lim_{i \rightarrow \infty} d(p, \exp a_i X_i) \\ &= \lim_{i \rightarrow \infty} a_i = \alpha. \end{aligned}$$

This shows that the geodesic $t \mapsto \exp tX$ is minimizing on $[0, \alpha]$, and consequently $a = \mu(X) \geq \alpha$. If $\alpha = \infty$, it is easy to see that we must again have $a \geq \alpha$. So in order to derive a contradiction from the assumption that $a \neq \alpha$, we can assume that $a > \alpha$. Thus we are assuming that the vectors $a_i X_i$ approach the vector αX with $\alpha < a$. This means, in particular, that \exp_* is not singular at αX , since a conjugate point cannot come before a cut point.

By choosing a subsequence of our sequence, we can assume that either each $\gamma_i(t) = \exp(ta_i X_i)$ satisfies (1) of Proposition 28, or else that each γ_i satisfies (2). If each γ_i satisfies (1), then \exp_* is singular at each $a_i X_i$. Hence \exp_* is singular at $\alpha X = \lim_{i \rightarrow \infty} a_i X_i$, a contradiction.

If each γ_i satisfies (2), then there are unit vectors $Y_i \neq X_i$ such that $\exp(a_i Y_i) = \exp(a_i X_i)$. Since \exp is a diffeomorphism on some open neighborhood U of αX , these vectors $a_i Y_i$ must lie outside U . By choosing a subsequence, we can assume that Y_i approach a unit vector Y at p . Clearly Y also lies outside U , so $Y \neq X$. But

$$\begin{aligned} d(p, \exp \alpha Y) &= \lim_{i \rightarrow \infty} d(p, \exp a_i Y_i) \\ &= \lim_{i \rightarrow \infty} d(p, \exp a_i X_i) \\ &= \lim_{i \rightarrow \infty} a_i = \alpha. \end{aligned}$$

This shows that $t \mapsto \exp tY$ is another minimal geodesic from p to $\exp(\alpha X)$. Since $\exp(\alpha X)$ comes before the cut point, this cannot occur, according to Proposition 27. ♦

As a particular consequence of Theorem 30, the map $\mu: M_p \rightarrow \mathbb{R}^*$ is continuous for each $p \in M$. Therefore the set

$$E(p) = \{tv : v \in M_p \text{ is a unit vector and } 0 \leq t < \mu(v)\}$$

is clearly homeomorphic to an open n -dimensional cell.

31. THEOREM. Let M be complete. Then $\exp: M_p \rightarrow M$ maps $E(p)$ diffeomorphically onto an open subset of M , and M is the disjoint union of $\exp E(p)$ and $C(p)$.

PROOF. Clearly \exp_* is one-one on $E(p)$, since there are no vectors $w \in E(p)$ with $\exp w$ conjugate to p . To see that \exp is one-one on $E(p)$, consider $w_1, w_2 \in E(p)$, with $\|w_1\| \leq \|w_2\|$, say. If we had $\exp w_1 = \exp w_2 = q$, then the geodesic $\omega(t) = \exp tw_1$ would have length from p to q less than or equal to that of the geodesic $\gamma(t) = \exp tw_2$. This contradicts Proposition 27, since q comes before the cut point of γ .

We next claim that $\exp E(p)$ and $C(p)$ are disjoint. If not, then there is $w \in E(p)$ and $u \in \tilde{C}(p)$ with $\exp w = \exp u = q$. If $\|u\| \leq \|w\|$, we have the same contradiction as before. If $\|w\| < \|u\|$ we still have a contradiction, for then $t \mapsto \exp tw$ would be a geodesic from p to q shorter than the geodesic $t \mapsto \exp tu$, which is minimal since $u \in \tilde{C}(p)$.

Finally, let q be any point of M . Then there is an arclength parameterized minimal geodesic $\gamma(t) = \exp tv$ from $p = \gamma(0)$ to $q = \gamma(a)$. Clearly $a \leq \mu(v)$. So $av \in E(p)$ or $av \in \tilde{C}(p)$. ♦

32. COROLLARY. If M is complete, and $p \in M$, then M is compact if and only if every geodesic through p has a cut point. In particular, if every geodesic through M has a conjugate point, then M is compact.

PROOF. We already know that if M is compact, then every geodesic through p has a cut point. On the other hand, if every such geodesic has a cut point, then $\tilde{C}(p) \subset M_p$ is homeomorphic to S^{n-1} , and $E(p) \cup \tilde{C}(p)$ is a compact set. So $M = \exp(E(p) \cup \tilde{C}(p))$ is also compact. ♦

One reason that the cut locus $C(p)$ is so important is that most of the topological properties of M are concentrated in $C(p)$. For it is easy to see that there is a deformation retraction of $M - \{p\}$ into $C(p)$ —we just push points of $\exp E(p) - \{p\}$ along geodesics through p until they hit $C(p)$. Thus the homotopy groups $\pi_k(C(p))$ and singular homology $H_k(C(p))$ groups are isomorphic

to $\pi_k(M - \{p\})$ and $H_k(M - \{p\})$, respectively; and there are well-known relations between these groups and $\pi_k(M)$ and $H_k(M)$.

Another simple consequence of Theorem 30 is:

33. COROLLARY. If M is complete, then the distance $d(p, C(p))$ between p and its cut locus is a continuous function of p .

We are now beginning to approach our goal, although it may not look like it. We first prove the following important lemma, which improves on Proposition 28 when $\gamma(a)$ is a special point in $C(p)$.

34. LEMMA. Let p be a point in a complete manifold M and let q be a point of $C(p)$ closest to p . Then at least one of the following holds:

- (1) The point q is conjugate to p along some minimal geodesic from p to q .
- (2) There are exactly two minimal geodesics from p to q , and their tangent vectors at q are negatives of each other, so that together they give a geodesic beginning and ending at p .

PROOF. Suppose (1) does not hold. Then by Proposition 28 there are at least two minimal geodesics γ_1 and γ_2 from p to q . We will show that the tangent vectors of any two such γ_1 and γ_2 are negatives of each other at q ; this clearly implies in addition that there is not a third minimal geodesic γ_3 from p to q .

Let K_1 be a “cone” formed by the points on all geodesics of length $d(p, q)$ whose tangent vectors lie in a neighborhood of γ_1' at p ; and define K_2 similarly. The set $\mathcal{E}(K_1)$ of all the endpoints of the geodesics making up K_1 is a hypersurface containing q . If the tangent vectors of γ_1 and γ_2 are not negatives of each other at q , then $\mathcal{E}(K_1)$ crosses the corresponding hypersurface $\mathcal{E}(K_2)$.

It follows that there is a point r with

$$r \in [K_1 - \varepsilon(K_1)] \cap [K_2 - \varepsilon(K_2)].$$

Now r is joined to p by a geodesic $\bar{\gamma}_1$ lying in K_1 , and a geodesic $\bar{\gamma}_2$ lying in K_2 . Since q is the point of $C(p)$ closest to p , the point r must come strictly before the first conjugate point on both γ_1 and γ_2 . But this is impossible by Proposition 27. ♦

When the point p of Lemma 34 is very special we can say even more.

35. LEMMA. Let p be a point in a complete manifold M for which the distance $d(p, C(p))$ is smallest, and let q be a point of $C(p)$ closest to p . Suppose that q is not conjugate to p along a minimal geodesic from p to q . Then there is a closed geodesic made up of two minimal geodesics from p to q .

PROOF. Since q is a point of $C(p)$ closest to p , there are, by Lemma 34, exactly two minimal geodesics γ_1 and γ_2 from p to q , and their tangent vectors are negatives of each other at q . But our hypotheses imply also that p is a point of $C(q)$ closest to q . So there are also exactly two minimal geodesics from q to p , namely γ_1 and γ_2 again, and their tangent vectors are negatives of each other at p . ♦

36. THEOREM (KLINGENBERG). Let M be a compact simply-connected even-dimensional Riemannian manifold whose sectional curvatures satisfy $0 < K(P)$ for all 2-dimensional $P \subset M_q$, for all $q \in M$. Then for some point $p \in M$, the cut locus $\tilde{C}(p)$ in M_p and the conjugate locus in M_p intersect.

Consequently, if we also have $K(P) \leq 1/r^2$ for some $r > 0$, then M has diameter $\geq \pi r$.

PROOF. Let p be a point for which $d(p, C(p))$ has the smallest value, L say, and let $q \in C(p)$ be a point closest to p . We claim that q is conjugate to p along a minimal geodesic. Suppose it were not. Then by Lemma 35, there is a closed geodesic $\gamma: [0, 1] \rightarrow M$, of length $2L$, made up of two minimal geodesics from p to q . By Synge's Lemma, there is a variation $\alpha: [0, \varepsilon] \times [0, 1] \rightarrow M$ of α such that all $\bar{\alpha}(u)$ are closed curves of length $< 2L$ for $u > 0$. This means that for each $u > 0$, the set of points $\{\alpha(u, t)\}$ is the image under $\exp_{\alpha(u, 0)}$ of a

set \mathcal{S}_u in $E(\alpha(u, 0))$; this set \mathcal{S}_u is a closed curve, since $\exp_{\alpha(u, 0)}$ is a diffeomorphism on $E(\alpha(u, 0))$. But the points of γ are *not* all in $\exp_p E(p)$. Instead, the set $\{\gamma(t)\} - \{q\}$ is the image of a set in $E(p)$; this set consists of two open rays from $0 \in M_p$ to two vectors $v, -v \in M_p$. We will show that such a situation cannot arise.

Let $\mathcal{S} = \bigcup_{u>0} \mathcal{S}_u$, and consider the set C of all points in \mathcal{S} corresponding to points of the form $\alpha(u, 1/2)$ for $u > 0$. We claim that C is connected. This is

because the map

$$u \mapsto \exp_{\alpha(u, 0)}^{-1}(\alpha(u, 1/2))$$

is continuous, where $\exp_{\alpha(u, 0)}^{-1}$ denotes the inverse of the map $\exp_{\alpha(u, 0)} : E(\alpha(u, 0)) \rightarrow M$. Similarly, if C_n is the set of all points in \mathcal{S} corresponding to points of the form $\alpha(u, 1/2)$ for $0 < u < \frac{1}{n}$, then C_n is also connected.

Now consider the set B_n of points in \mathcal{S} corresponding to points of the form

$$\alpha(u, t) \quad \text{for } t \in \left(\frac{1}{2} - \frac{1}{n}, \frac{1}{2} + \frac{1}{n}\right) \quad \text{and } 0 < u < \frac{1}{n}.$$

The set B_n is also connected: it consists of the union of connected sets in δ_u for $0 < u < \frac{1}{n}$, and each of these contains a point of the connected set C_n .

Finally, consider the set

$$B = \bigcap_n \overline{B_n}.$$

As a decreasing intersection of compact, connected sets, it is also connected. It is clear that it is completely contained in M_p , and that it contains both v and $-v$. Therefore it must contain some other vector $w \in M_p$. But then it is easy to see that $t \mapsto \exp tw$ is another minimal geodesic from p to q , contradicting Lemma 34. ♦

PROBLEMS

1. Suppose that f satisfies the condition for second derivatives on page 204.
 - (a) Show that if f is composed with a suitable rotation, then the corresponding matrix $(\partial^2 f / \partial x_i \partial x_j)$ is diagonal (compare pg. II.50).
 - (b) Conclude that f has a local minimum at x .
 - (c) For $f(x, y) = (y - x^2)(y - 2x^2)$, show that f has a strict local minimum along every straight line through x , but that f does not have a local minimum at x .

2. (a) Prove the following “delicate Sturm comparison theorem”: Let f and h be two continuous functions $f \leq h$ on an open interval (a, b) , and let ϕ and η be two functions satisfying

$$\begin{aligned} (1) \quad & \phi'' + f\phi = 0 \\ (2) \quad & \eta'' + h\eta = 0 \end{aligned}$$

on (a, b) . Assume that $\phi(t) \neq 0$ for $t \in (a, b)$, and that

$$\lim_{t \rightarrow a^+} \phi(t) = \lim_{t \rightarrow b^-} \phi(t) = 0.$$

Then η must have a zero on (a, b) , unless $f = h$ everywhere on (a, b) and η is a constant multiple of ϕ on (a, b) .

(b) In the situation considered on page 231, let $V = d\gamma/dt$, and let Y be the unit vector field along $\gamma|(0, L)$ which is perpendicular to V and tangent to image α along $\gamma|(0, L)$. Let $W = fV + \phi Y$ be the decomposition of Proposition 3 for image α ; note that f and ϕ have (left- and right-hand) limits 0 at 0 and L . Conclude that $f = 0$ and that ϕ satisfies the hypotheses of part (a). Thus obtain a contradiction, demonstrating that we cannot have $L < \pi r$.

3. (a) Let M be a non-orientable C^∞ manifold. Let \tilde{M} be the set of all orientations μ_p for M_p , for all $p \in M$, and define $\pi: \tilde{M} \rightarrow M$ to be the map which takes each of the two orientations of M_p into p . Show that \tilde{M} has a natural C^∞ structure that makes $\pi: \tilde{M} \rightarrow M$ a 2-fold covering space of M , and that \tilde{M} is orientable.

(b) If M is a compact, connected, non-orientable, even-dimensional Riemannian manifold with all sectional curvatures positive, then $\pi_1(M) \approx \mathbb{Z}_2$.

(c) Let $c, \gamma: [0, 1] \rightarrow M$ be freely homotopic closed curves, and let $\tilde{c}, \tilde{\gamma}: [0, 1] \rightarrow \tilde{M}$ be curves with $\pi \circ \tilde{c} = c$ and $\pi \circ \tilde{\gamma} = \gamma$. Then $\tilde{c}(0) = \tilde{c}(1)$ if and only if $\tilde{\gamma}(0) = \tilde{\gamma}(1)$. Hence if M is non-orientable, then there is a closed curve $c: [0, 1] \rightarrow M$ of minimal length such that $\tilde{c}(0) \neq \tilde{c}(1)$.

(d) If M is a compact, connected, odd-dimensional Riemannian manifold with all sectional curvatures positive, then M is orientable.

CHAPTER 9

VARIATIONS OF LENGTH, AREA, AND VOLUME

The classical calculus of variations was extended, quite soon after its inception, to deal with problems in several variables. In this chapter we will use these methods to study n -dimensional submanifolds $M \subset (N^m, \langle \cdot, \cdot \rangle)$ with minimal n -dimensional volume. Thus the material of this chapter may be regarded as a generalization of the study of geodesics which was carried out in Chapter I.9 and in Chapter 8 of this Volume. One big difference, aside from the greater difficulties to be encountered, is the fact that our results are truly extrinsic—all our theorems will be about the submanifolds of N , not about the structure of N itself.

When we look for curves which have the shortest length among all curves between 2 fixed endpoints, we find that the only possible candidates are geodesics (provided that we parameterize all curves proportionally to arclength). For the 2-dimensional analogue of this situation, we replace the two fixed endpoints in our Riemannian manifold $(N, \langle \cdot, \cdot \rangle)$ by a compact 1-dimensional manifold M_0 (diffeomorphic to a finite union of circles). We then consider all immersed compact 2-dimensional manifolds-with-boundary M satisfying $\partial M = M_0$. Among these, we seek one which has minimum area; by the **area** of an immersed sur-

face $f: M \rightarrow N$ we mean the integral over M of the (2-dimensional) volume element dA determined by the induced metric $f^*\langle \cdot, \cdot \rangle$ (when M is oriented, we can consider dA to be a 2-form). Our approach to this problem will be similar to our approach in the analogous 1-dimensional case; we will find “critical points” for the area function. One important difference is that no particular parameterization of M will play a favored role.

Before we try to find a general formula for the “variation of area”, we will first investigate the case of surfaces in \mathbb{R}^3 , which leads to an extraordinarily rich theory, of a very special sort. At first, we will not even consider general immersed surfaces-with-boundary, but only immersions $f: D \rightarrow \mathbb{R}^3$, where $D \subset \mathbb{R}^2$ is a compact 2-dimensional manifold-with-boundary. By a **variation** α of f we will mean a C^∞ function $\alpha: (-\varepsilon, \varepsilon) \times D \rightarrow \mathbb{R}^3$ with $\alpha(0, p) = f(p)$ for $p \in D$; for each $u \in (-\varepsilon, \varepsilon)$, we then define the function $\bar{\alpha}(u): D \rightarrow \mathbb{R}^3$ by $\bar{\alpha}(u)(p) = \alpha(u, p)$. Since $f = \bar{\alpha}(0)$ is an immersion, the same must be true of $\bar{\alpha}(u)$ for sufficiently small u (one needs compactness of D to prove this), so with no loss of generality we can assume that all $\bar{\alpha}(u)$ are immersions. As in the previous chapter, we define the **variation vector field** W by

$$W(p) = \frac{\partial \alpha}{\partial u}(0, p);$$

notice that $W(p) \in \mathbb{R}^3_{f(p)}$, so that W is a “vector field along f ”.

In almost every differential geometry book under the sun, the only variations considered are those of the form

$$(I) \quad \alpha(u, t_1, t_2) = f(t_1, t_2) + u \cdot \phi(t_1, t_2) \cdot N(t_1, t_2),$$

where $N(t_1, t_2)$ is the unit normal at $f(t_1, t_2)$, and ϕ is some C^∞ function. Thus α is a very special sort of “normal variation”—each curve $u \mapsto \alpha(u, t_1, t_2)$ is a straight line normal to the surface f , and the variation vector field W is just

$$W(t_1, t_2) = \phi(t_1, t_2) \cdot N(t_1, t_2).$$

The decision to ignore more general variations is partially justified by the following observations. In the first place, if we are given a variation $\alpha: (-\varepsilon, \varepsilon) \times D \rightarrow \mathbb{R}^3$ of f , then we can usually find a new variation $\beta: (-\varepsilon', \varepsilon') \times D \rightarrow \mathbb{R}^3$ of f such that

- (a) $\frac{\partial \beta}{\partial u}(0, p)$ is perpendicular to $f(D)$,
- (b) the surfaces $\bar{\alpha}(u)(D)$ and $\bar{\beta}(u)(D)$ are always the same, even though the parameterizations $\bar{\alpha}(u)$ and $\bar{\beta}(u)$ may be different.

To do this, we assume that the surfaces $\bar{\alpha}(u)(D)$ are all disjoint, and we consider the curves, parameterized by arclength, which are orthogonal to all the surfaces $\bar{\alpha}(u)(D)$. Then we let $\beta(u, p)$ be the unique point of $\bar{\alpha}(u)(D)$ which lies on

the curve passing through $f(p)$. Thus we can usually assume that our variation vector field W is perpendicular to $f(D)$. In the second place, when we take the derivative at 0 of the areas of the surfaces $\bar{\alpha}(u)(D)$, we naturally expect that the answer will depend only on W , exactly as in the case of arclength. If this expectation is correct, then we can even assume that α is of the form (1). This line of argument, intuitively reasonable as it may be, is perhaps not very satisfying. But we will have adequate opportunity to consider more general variations later on, when we re-examine surfaces immersed in an arbitrary Riemannian manifold. So for the time being, let us indulge in the classical simplification, which makes the calculations so much more manageable.

For the special variation given by (1) we have

$$(2) \quad \frac{\partial \alpha}{\partial t_i}(u, t_1, t_2) = \frac{\partial f}{\partial t_i} + u \cdot \frac{\partial \phi}{\partial t_i} \cdot N + u \cdot \phi \cdot \frac{\partial N}{\partial t_i} \quad [\text{all partials on the right evaluated at } (t_1, t_2)].$$

Let

$$(3) \quad g_{ij}(u)(t_1, t_2) = \left\langle \frac{\partial \alpha}{\partial t_i}(u, t_1, t_2), \frac{\partial \alpha}{\partial t_j}(u, t_1, t_2) \right\rangle,$$

so that the functions $g_{ij}(u)$ are the components of $\bar{\alpha}(u)^*(\ , \)$; in particular, then, $g_{ij} = g_{ij}(0)$ are the components of $f^*(\ , \)$. Since

$$\left\langle \frac{\partial f}{\partial t_i}, \frac{\partial N}{\partial t_j} \right\rangle = -l_{ij}, \quad \left\langle \frac{\partial f}{\partial t_i}, N \right\rangle = 0,$$

equations (2) and (3) give

$$g_{ij}(u) = g_{ij} - 2u\phi l_{ij} + u^2 a_{ij}(u),$$

where $(u, t_1, t_2) \mapsto a_{ij}(u)(t_1, t_2)$ is some continuous function. From this we obtain

$$\begin{aligned}\det g_{ij}(u) &= \det g_{ij} - 2u\phi[g_{11}l_{22} + g_{22}l_{11} - 2g_{12}l_{12}] + u^2b(u) \\ &= (\det g_{ij})[1 - 4u\phi H] + u^2b(u), \quad \text{by formula (B) of Chapter 3;}\end{aligned}$$

in this equation, $b(u)$ is a function having the same property as the $a_{ij}(u)$. It is now easy to see that

$$\left. \frac{\partial}{\partial u} \right|_{u=0} \det g_{ij}(u) = -4\phi H \det g_{ij},$$

from which we obtain

$$\left. \frac{\partial}{\partial u} \right|_{u=0} \sqrt{\det g_{ij}(u)} = -2\phi H \sqrt{\det g_{ij}}.$$

Let us denote by $A(\bar{\alpha}(u))$ the area of the immersed surface $\bar{\alpha}(u): D \rightarrow \mathbb{R}^3$. Then

$$\begin{aligned} (*) \quad \left. \frac{dA(\bar{\alpha}(u))}{du} \right|_{u=0} &= \left. \frac{d}{du} \right|_{u=0} \int_D \sqrt{\det g_{ij}(u)} \, dt_1 \, dt_2 \\ &= \int_D \left. \frac{\partial}{\partial u} \right|_{u=0} \sqrt{\det g_{ij}(u)} \, dt_1 \, dt_2 \\ &= - \int_D 2\phi H \sqrt{\det g_{ij}} \, dt_1 \, dt_2 \\ &= - \int_D 2\phi H \, dA, \quad dA = \begin{array}{l} \text{volume element on } D \text{ for} \\ \text{the metric } f^*\langle \cdot, \cdot \rangle. \end{array}\end{aligned}$$

We are now ready to draw a conclusion.

1. PROPOSITION. Let M be a compact 2-dimensional manifold-with-boundary; and $f: M \rightarrow \mathbb{R}^3$ an immersion such that $f(\partial M)$ is a given compact 1-manifold $M_0 \subset \mathbb{R}^3$. If M is a critical point for the area function, among all such immersions, then M must be a minimal surface ($H = 0$ everywhere). In particular, if M has the minimum area among all such surfaces, then M is a minimal surface.

PROOF. Suppose that $H(p) \neq 0$ for some $p \in M$, say $H(p) > 0$. Choose a neighborhood \mathcal{D} of p so small that $H(q) > 0$ for all $q \in \mathcal{D}$. We can assume that $f(\mathcal{D})$ is also the image $g(D)$ for some immersion $g: D \rightarrow \mathbb{R}^3$ of a compact 2-dimensional manifold-with-boundary $D \subset \mathbb{R}^2$. Let $\phi: D \rightarrow \mathbb{R}$ be a C^∞

function which is ≥ 0 on D and $= 0$ in a neighborhood of ∂D . We can then define a variation α of f by letting

$$\begin{aligned} \alpha(u, p) &= f(p) & p \notin \mathcal{D} \\ \alpha(u, p) &= f(p) + u \cdot \phi(\bar{p}) \cdot N(\bar{p}), & \text{for } \bar{p} = g^{-1}(f(p)), \quad p \in \mathcal{D}. \end{aligned}$$

Formula (*) shows that

$$\left. \frac{dA(\bar{\alpha}(u))}{du} \right|_{u=0} = - \int_D 2\phi \tilde{H} dA,$$

where $\tilde{H}(t_1, t_2)$ is the mean curvature H at $f^{-1}(g(t_1, t_2))$. Since $\tilde{H} > 0$ everywhere on D , and since ϕ is ≥ 0 on D , but is not identically 0, the integral is positive; this is a contradiction. ♦

In the statement of Proposition 1 we have deliberately *not* claimed that a minimal surface actually is a critical point for the area function. We found that $H = 0$ is a *necessary* condition for a critical point by considering variations α which, first of all, vanish outside a small region, and, second of all, are normal to the surface. It is conceivable (well, just barely) that if we considered arbitrary variations, we would obtain another condition more stringent than $H = 0$. So we will have to wait a bit before we can assert with assurance that minimal surfaces are precisely the critical points for the area function. On the other hand, the second part of Proposition 1 is already the best we can hope for: among those surfaces with boundary M_0 , the one with minimum area must be a minimal surface; but we would not expect every minimal surface to have this property, any more than we expect every geodesic to be the shortest length between its endpoints.

The next result only begins to suggest how special minimal surfaces are.

2. PROPOSITION. Let M be an immersed surface in \mathbb{R}^3 with normal map $N: M \rightarrow S^2$. If M is minimal, then N is conformal (angle preserving) at all points where $K \neq 0$. Conversely, if N is conformal, and M is connected, then either M is a minimal surface, with $K < 0$ everywhere, or M is part of a sphere.

PROOF. Recall (Lemma II.7-20) that the map N is conformal at p if and only if there is $\mu(p) \neq 0$ such that

$$(1) \quad \langle N_* X_p, N_* Y_p \rangle = \mu(p) \langle X_p, Y_p \rangle \quad X_p, Y_p \in M_p.$$

We will make use of the third fundamental form III of M , which was defined in Chapter 2:

$$\begin{aligned} \text{III}(p)(X_p, Y_p) &= \langle N_* X_p, N_* Y_p \rangle \\ &= \langle N_*^2(X_p), Y_p \rangle, \quad \text{for } X_p, Y_p \in M_p. \end{aligned}$$

By Proposition 2-6 we have

$$(2) \quad \text{III} - 2H \cdot \text{II} + K \cdot \text{I} = 0.$$

Suppose first that M is minimal. Then (2) gives $\text{III} = -K \cdot \text{I}$, which shows that (1) holds with $\mu(p) = -K(p)$; hence N is conformal when $K(p) \neq 0$.

Conversely, suppose that N is conformal, so that it satisfies (1) for some function μ which is non-zero, and hence obviously positive. Then (2) gives

$$(K + \mu) \cdot \text{I} - 2H \cdot \text{II} = 0.$$

At a point p with $H(p) \neq 0$ we can therefore write $\text{II}(p)$ as a multiple of $\text{I}(p)$, which means that p is an umbilic. At a point p with $H(p) = 0$, we have $K(p) = -\mu(p) < 0$, so p cannot be an umbilic. In short,

$$p \text{ is an umbilic if and only if } H(p) \neq 0.$$

The set of umbilics is thus open. But it is also closed. So either: no points are umbilics, and $H = 0$ everywhere; or all points p are umbilics, and these umbilics are not flat points (since $H(p) \neq 0$), so M is part of a sphere. ♦

Back in Volume II, pg. 297, we mentioned that every 2-dimensional Riemannian manifold M is locally conformally equivalent to the plane: around each point p we can choose an “isothermal” coordinate system for which we have $g_{ij} = \mu \delta_{ij}$. Addendum I contains a proof of this result for general Riemannian 2-manifolds. On the other hand, Proposition 2 provides an easy way

of introducing isothermal coordinates around any non-flat point p of a minimal surface M . We need only find a conformal map $\sigma: S^2 - \{\text{point}\} \rightarrow \mathbb{R}^2$, and then $\sigma \circ N$ will be the required isothermal coordinate system in a neighborhood of p . But we already know such a conformal map σ , namely stereographic projection. It will be convenient to use the second version of stereographic projection, given on page 107. Recall that

$$\sigma(a, b, c) = \left(\frac{a}{1-c}, \frac{b}{1-c} \right)$$

$$\sigma^{-1}(x, y) = \left(\frac{2x}{x^2 + y^2 + 1}, \frac{2y}{x^2 + y^2 + 1}, \frac{x^2 + y^2 - 1}{x^2 + y^2 + 1} \right).$$

Naturally, we can find a conformal map $S^2 - \{q\} \rightarrow \mathbb{R}^2$ for any other point q merely by first rotating S^2 so that q goes to $(0, 0, 1)$.

Unfortunately, this method does not work at a flat point. To include such points we can, of course, appeal to the result of Addendum 1, valid for all surfaces. However, for minimal surfaces there is a considerably easier argument that still works at all points.

3. PROPOSITION. Isothermal coordinates can be introduced around any point of a minimal surface $M \subset \mathbb{R}^3$.

PROOF. We can assume that M is the graph of a function $h: U \rightarrow \mathbb{R}$, for $U \subset \mathbb{R}^2$, so that M is the image of the map $f(x, y) = (x, y, h(x, y))$. Introducing the classical notation

$$p = \frac{\partial h}{\partial x}, \quad q = \frac{\partial h}{\partial y},$$

$$r = \frac{\partial^2 h}{\partial x^2}, \quad s = \frac{\partial^2 h}{\partial x \partial y}, \quad t = \frac{\partial^2 h}{\partial y^2},$$

and using equation (B') on pg. III.137, we have

$$(1) \quad (1 + q^2)r - 2pqs + (1 + p^2)t = 0.$$

Setting

$$W = \sqrt{1 + p^2 + q^2},$$

we note that

$$\begin{aligned} \frac{\partial}{\partial x} \left(\frac{1 + q^2}{W} \right) - \frac{\partial}{\partial y} \left(\frac{pq}{W} \right) &= -\frac{p}{W^3} [(1 + q^2)r - 2pqs + (1 + p^2)t] \\ &= 0 \quad \text{by (1),} \end{aligned}$$

and similarly

$$\frac{\partial}{\partial x} \left(\frac{pq}{W} \right) - \frac{\partial}{\partial y} \left(\frac{1 + p^2}{W} \right) = 0.$$

This means that we can locally find functions α and β with

$$(2) \quad \begin{array}{ll} \text{(a)} \quad \frac{\partial \alpha}{\partial x} = \frac{1 + p^2}{W} & \text{(c)} \quad \frac{\partial \beta}{\partial x} = \frac{pq}{W} \\ \text{(b)} \quad \frac{\partial \alpha}{\partial y} = \frac{pq}{W} & \text{(d)} \quad \frac{\partial \beta}{\partial y} = \frac{1 + q^2}{W}. \end{array}$$

Consider the *transformation of Lewy*:

$$T(x, y) = (x + \alpha(x, y), y + \beta(x, y)).$$

Its Jacobian is

$$J(T)(x, y) = \begin{pmatrix} 1 + \frac{1 + p^2}{W} & \frac{pq}{W} \\ \frac{pq}{W} & 1 + \frac{1 + q^2}{W} \end{pmatrix},$$

with determinant

$$2 + \frac{2 + p^2 + q^2}{W} \geq 2.$$

So T has an inverse locally, and

$$\begin{aligned} J(T^{-1})(T(x, y)) &= [J(T)(x, y)]^{-1} \\ &= \frac{1}{\det J(T)(x, y)} \begin{pmatrix} 1 + \frac{1 + q^2}{W} & -\frac{pq}{W} \\ -\frac{pq}{W} & 1 + \frac{1 + p^2}{W} \end{pmatrix} \\ &= C \begin{pmatrix} 1 + W + q^2 & -pq \\ -pq & 1 + W + p^2 \end{pmatrix} \quad \text{for some } C. \end{aligned}$$

So

$$\begin{aligned}
 J(f \circ T^{-1})(T(x, y)) &= J(f)(x, y) \cdot J(T^{-1})(T(x, y)) \\
 &= C \cdot \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ p & q \end{pmatrix} \begin{pmatrix} 1 + W + q^2 & -pq \\ -pq & 1 + W + p^2 \end{pmatrix} \\
 &= C \cdot \begin{pmatrix} 1 + W + q^2 & -pq \\ -pq & 1 + W + p^2 \\ p + pW & q + qW \end{pmatrix}.
 \end{aligned}$$

It is easy to check that the two column vectors in this matrix are orthogonal, and that they have the same squared length

$$(1 + p^2 + q^2)(2W + 2 + p^2 + q^2).$$

Thus $f \circ T^{-1}$ is conformal, and its inverse is the desired isothermal coordinate system. ♦

The reader has probably noticed the similarity between this proof and the proof of Jörgens' Theorem (7-45). As a matter of fact, that proof of Jörgens' Theorem was motivated by manipulations with the minimal surface equation, and the original application of Jörgens' Theorem itself had been to reprove a result about minimal surfaces:

4. THEOREM (BERNSTEIN). Planes are the only minimal surfaces in \mathbb{R}^3 which are the graph of a function $h: \mathbb{R}^2 \rightarrow \mathbb{R}$.

PROOF. Suppose we have a function $h: \mathbb{R}^2 \rightarrow \mathbb{R}$ satisfying equation (1) in the previous proof. Then the functions α and β of equation (2) are defined on all of \mathbb{R}^2 (since \mathbb{R}^2 is simply-connected). From (b) and (c) of equation (2) we see that there is a function $\phi: \mathbb{R}^2 \rightarrow \mathbb{R}$ with

$$\phi_x = \alpha \quad \text{and} \quad \phi_y = \beta.$$

Together with (a) and (d), we then have

$$\phi_{xx} = \frac{1 + p^2}{W}, \quad \phi_{xy} = \frac{pq}{W}, \quad \phi_{yy} = \frac{1 + q^2}{W},$$

which implies that

$$\phi_{xx}\phi_{yy} - (\phi_{xy})^2 = 1.$$

Jörgens' Theorem implies that

$$\frac{1+p^2}{W}, \quad \frac{pq}{W}, \quad \frac{1+q^2}{W}$$

are constants. A simple exercise then shows that p and q must be constants. ♦

The manipulations of the past few pages were undoubtedly unpleasant (not to say, slightly unmotivated), but they were really worth the trouble, because isothermal coordinates play such a vital role in the study of minimal surfaces.

5. PROPOSITION. If $f: M \rightarrow \mathbb{R}^3$ is a minimal immersion, and (u^1, u^2) is an isothermal coordinate system on M , then

$$\frac{\partial^2 f^i}{\partial u^1 \partial u^1} + \frac{\partial^2 f^i}{\partial u^2 \partial u^2} = 0 \quad i = 1, 2, 3.$$

Conversely, if this equation holds for a collection of isothermal coordinate systems covering M , then f is a minimal immersion.

PROOF. By equation (7) on page 136 we have

$$\Delta f = 2HN,$$

where N is the normal map, and Δ is the Laplacian. Therefore f is minimal if and only if $\Delta f^i = 0$ for $i = 1, 2, 3$. Since our coordinate system (u^1, u^2) is isothermal, Problem 7-23 shows that

$$\Delta f^i = \frac{1}{E} \left(\frac{\partial^2 f^i}{\partial u^1 \partial u^1} + \frac{\partial^2 f^i}{\partial u^2 \partial u^2} \right). \quad \diamond$$

Let us rephrase Proposition 5 just slightly. If $u = (u^1, u^2): U \rightarrow V \subset \mathbb{R}^2$ is an isothermal coordinate system on $U \subset M$, and $f: M \rightarrow \mathbb{R}^3$ is a minimal immersion, then each real-valued function $g^i = f^i \circ u^{-1}: V \rightarrow \mathbb{R}$ satisfies "Laplace's equation"

$$\frac{\partial^2 g^i}{\partial x^2} + \frac{\partial^2 g^i}{\partial y^2} = 0,$$

where $\partial/\partial x$ and $\partial/\partial y$ denote the ordinary partial derivatives in \mathbb{R}^2 . Now at this point complex analysis comes rushing in, waving its hands excitedly in its eagerness to enlighten us. It is a well-known result that locally any such function is the real part of a complex analytic function; we recall the argument briefly:

Suppose that g satisfies Laplace's equation

$$\frac{\partial^2 g}{\partial x^2} + \frac{\partial^2 g}{\partial y^2} = 0,$$

which we can also write as

$$\frac{\partial\left(\frac{\partial g}{\partial x}\right)}{\partial x} = \frac{\partial\left(-\frac{\partial g}{\partial y}\right)}{\partial y}.$$

According to Proposition I.6-0, there is locally a function h such that

$$\frac{\partial h}{\partial x} = -\frac{\partial g}{\partial y} \quad \frac{\partial h}{\partial y} = \frac{\partial g}{\partial x}.$$

But these are just the Cauchy-Riemann equations for $g + ih$, showing that this function is complex analytic, with real part $\operatorname{Re}(g + ih) = g$. The converse is even easier: If g is the real part of a complex analytic function $g + ih$, then the Cauchy-Riemann equations immediately lead to Laplace's equation for g .

A minimal surface M can thus be represented locally by

$$(x, y) \mapsto \Phi(x, y) = (\operatorname{Re} \phi_1(x + iy), \operatorname{Re} \phi_2(x + iy), \operatorname{Re} \phi_3(x + iy)) \in \mathbb{R}^3,$$

where the ϕ_i are complex analytic functions, and Φ itself is the inverse of an isothermal coordinate system. As one consequence of this representation, we see that every minimal surface in \mathbb{R}^3 is *automatically* real analytic (C^ω).

The fact that Φ^{-1} is an isothermal coordinate system can just as well be expressed by saying that Φ is conformal, and hence by the following two equations for the vectors $\partial\Phi/\partial x, \partial\Phi/\partial y \in \mathbb{R}^3$:

$$\left\langle \frac{\partial\Phi}{\partial x}, \frac{\partial\Phi}{\partial x} \right\rangle = \left\langle \frac{\partial\Phi}{\partial y}, \frac{\partial\Phi}{\partial y} \right\rangle \quad \left\langle \frac{\partial\Phi}{\partial x}, \frac{\partial\Phi}{\partial y} \right\rangle = 0.$$

Since the complex derivative ϕ_k' is given by

$$\begin{aligned} \phi_k'(x + iy) &= \frac{\partial \operatorname{Re} \phi_k}{\partial x} + i \frac{\partial \operatorname{Im} \phi_k}{\partial x} \\ &= \frac{\partial \operatorname{Re} \phi_k}{\partial x} - i \frac{\partial \operatorname{Re} \phi_k}{\partial y} \\ &= \frac{\partial \Phi^k}{\partial x} - i \frac{\partial \Phi^k}{\partial y}, \end{aligned}$$

our pair of equations for Φ is equivalent to the one complex equation $\sum_k (\phi_k')^2 = 0$; in terms of the functions $\psi_k = \phi_k'$ we can thus write our conditions as

$$\psi_1^2 + \psi_2^2 + \psi_3^2 = 0.$$

Now we can describe the solutions of this equation explicitly.

6. LEMMA. Let $V \subset \mathbb{C}$ be open, let g be meromorphic in V , and let f be analytic in V with a zero of order at least $2m$ at each point where g has a pole of order m . Then the functions

$$\psi_1 = \frac{1}{2}f(1 - g^2), \quad \psi_2 = \frac{i}{2}f(1 + g^2), \quad \psi_3 = fg$$

are analytic in V and satisfy $\psi_1^2 + \psi_2^2 + \psi_3^2 = 0$. Conversely, every triple ψ_1, ψ_2, ψ_3 of analytic functions satisfying $\psi_1^2 + \psi_2^2 + \psi_3^2 = 0$ on V can be represented this way.

PROOF. The first half of the Lemma is a direct calculation. Suppose, conversely, that we are given functions ψ_i satisfying the equation $\psi_1^2 + \psi_2^2 + \psi_3^2 = 0$, which we can also write in the form

$$(1) \quad (\psi_1 - i\psi_2)(\psi_1 + i\psi_2) = -\psi_3^2.$$

If ψ_3 is the 0 function, we choose $g = 0$ and $f = 2\psi_1$. If ψ_3 is not the 0 function, then $\psi_1 - i\psi_2$ is also not the 0 function, so we can define

$$(2) \quad f = \psi_1 - i\psi_2, \quad g = \frac{\psi_3}{\psi_1 - i\psi_2},$$

with f analytic and g meromorphic. Then equation (1) gives

$$(3) \quad \psi_1 + i\psi_2 = \frac{-\psi_3^2}{\psi_1 - i\psi_2} = -fg^2.$$

Equation (3) together with the definition of f in equation (2) shows that the ψ_i have the desired form. Equation (3) also shows that fg^2 is analytic, so f must have a zero of order at least $2m$ at each point where g has a pole of order m . ♦

It is now a simple matter to give a representation of minimal surfaces, due to Enneper and Weierstrass, which plays a major role in the theory.

7. THEOREM. Every point of a minimal surface $M \subset \mathbb{R}^3$ is in the image of some conformal map $\Phi: V \rightarrow M \subset \mathbb{R}^3$, where $V \subset \mathbb{C}$ is a simply-connected open set. Each such conformal map Φ is of the form $\Phi = \Phi_{(f,g)}$, where

$$\Phi_{(f,g)}^1(x, y) = \operatorname{Re} \int \frac{1}{2} f(w)(1 - g(w)^2) dw + c_1$$

$$\Phi_{(f,g)}^2(x, y) = \operatorname{Re} \int \frac{i}{2} f(w)(1 + g(w)^2) dw + c_2$$

$$\Phi_{(f,g)}^3(x, y) = \operatorname{Re} \int f(w)g(w) dw + c_3.$$

In these equations, the c_i are real numbers, g is meromorphic on V , and f is an analytic function on V vanishing precisely at the poles of g , the order of the zero being exactly twice the order of the pole; the integrals are taken along any path from a fixed point $x_0 + iy_0 \in V$ to the point $x + iy$.

Conversely, every such $\Phi_{(f,g)}$ is a conformal map into a minimal surface.

PROOF. We have already seen that there is a conformal map $\Phi: V \rightarrow M \subset \mathbb{R}^3$ given by

$$(1) \quad \Phi^k(x, y) = \operatorname{Re} \phi_k(x + iy),$$

for complex analytic functions ϕ_k satisfying

$$(2) \quad \sum_k (\phi_k')^2 = 0.$$

By Lemma 6 we have

$$(3) \quad \phi_1' = \frac{1}{2}f(1 - g^2), \quad \phi_2' = \frac{i}{2}f(1 + g^2), \quad \phi_3' = fg,$$

where f has a zero of order at least $2m$ at each point where g has a pole of order m . We just have to show that the order of f is exactly $2m$ at such a pole. Now if we had $\phi_1'(x + iy) = \phi_2'(x + iy) = 0$, then we would also have $\phi_3'(x + iy) = 0$ by (2). Since

$$(4) \quad \phi_k'(x + iy) = \frac{\partial \Phi^k}{\partial x} - i \frac{\partial \Phi^k}{\partial y},$$

this would mean that $\partial \Phi / \partial x = \partial \Phi / \partial y = 0$ at (x, y) , contradicting the fact that Φ is conformal (and hence an immersion). So $\phi_k'(x + iy) \neq 0$ for $k = 1$ or 2 (or both). Then equation (3) implies that the order of f is at most $2m$ at a pole of g of order m .

Conversely, consider $\Phi = \Phi_{(f,g)}$ where f and g have the stated properties. Then we have equation (1), where the ϕ_k are given by (3), and hence satisfy (2). It follows from (2) and (4) that

$$(5) \quad \left\langle \frac{\partial \Phi}{\partial x}, \frac{\partial \Phi}{\partial x} \right\rangle = \left\langle \frac{\partial \Phi}{\partial y}, \frac{\partial \Phi}{\partial y} \right\rangle, \quad \left\langle \frac{\partial \Phi}{\partial x}, \frac{\partial \Phi}{\partial y} \right\rangle = 0.$$

Now our hypotheses on f and g imply [by (3)] that ϕ_1' and ϕ_2' are nowhere zero, and thus that $\partial\Phi/\partial x$ and $\partial\Phi/\partial y$ are nowhere zero. Since they are also orthogonal, by (5), they are linearly independent, so the map Φ is an immersion, and thus a conformal immersion into its image. Since the Φ^k are the real parts of complex analytic functions, they satisfy Laplace's equation, so Φ is also a minimal immersion, by Proposition 5. ♦

In order to connect this with the differential geometric properties of minimal surfaces, we need the following additional information, which will also explain the significance of the poles of g .

8. PROPOSITION. For the immersion $\Phi = \Phi_{(f,g)}$ of Theorem 7, the metric $\Phi^*\langle \cdot, \cdot \rangle$ on V has components $g_{ij} = \mu\delta_{ij}$, where

$$\mu(z) = \left[\frac{|f(z)|(1 + |g(z)|^2)}{2} \right]^2$$

[this expression will approach some limit at z if z is a pole of g].

If N is the normal map of Φ , then

$$N(z) = \left(\frac{2 \operatorname{Re} g(z)}{|g(z)|^2 + 1}, \frac{2 \operatorname{Im} g(z)}{|g(z)|^2 + 1}, \frac{|g(z)|^2 - 1}{|g(z)|^2 + 1} \right) \in S^2$$

[$= (0, 0, 1) \in S^2$ if z is a pole of g].

PROOF. Since Φ is conformal, we have $g_{ij} = \mu\delta_{ij}$, where

$$\mu = \left\langle \frac{\partial\Phi}{\partial x}, \frac{\partial\Phi}{\partial x} \right\rangle = \left\langle \frac{\partial\Phi}{\partial y}, \frac{\partial\Phi}{\partial y} \right\rangle.$$

Using

$$\phi_k'(x + iy) = \frac{\partial\Phi^k}{\partial x} - i \frac{\partial\Phi^k}{\partial y}$$

and equation (3) of the previous proof, this gives

$$\mu(z) = \frac{1}{2} \sum_k |\phi_k'(z)|^2 = \left[\frac{|f(z)|(1 + |g(z)|^2)}{2} \right]^2.$$

We also see that at points where g does not have a pole, we have

$$\begin{aligned} \frac{\partial \Phi}{\partial x} \times \frac{\partial \Phi}{\partial y} &= (\operatorname{Re} \phi_1', \operatorname{Re} \phi_2', \operatorname{Re} \phi_3') \times -(\operatorname{Im} \phi_1', \operatorname{Im} \phi_2', \operatorname{Im} \phi_3') \\ &= (\operatorname{Re} \phi_3' \operatorname{Im} \phi_2' - \operatorname{Re} \phi_2' \operatorname{Im} \phi_3', \dots) \\ &= (\operatorname{Im} \phi_2 \bar{\phi}_3, \operatorname{Im} \phi_3 \bar{\phi}_1, \operatorname{Im} \phi_1 \bar{\phi}_2) \\ &= \frac{|f|^2(1 + |g|^2)}{4} (2 \operatorname{Re} g, 2 \operatorname{Im} g, |g|^2 - 1). \end{aligned}$$

From this we compute that

$$\left| \frac{\partial \Phi}{\partial x} \times \frac{\partial \Phi}{\partial y} \right| = \left[\frac{|f|(1 + |g|^2)}{2} \right]^2 = \mu,$$

which we should have known anyway, and finally get

$$\frac{\frac{\partial \Phi}{\partial x} \times \frac{\partial \Phi}{\partial y}}{\left| \frac{\partial \Phi}{\partial x} \times \frac{\partial \Phi}{\partial y} \right|} = \left(\frac{2 \operatorname{Re} g}{|g|^2 + 1}, \frac{2 \operatorname{Im} g}{|g|^2 + 1}, \frac{|g|^2 - 1}{|g|^2 + 1} \right).$$

As we approach a pole, this clearly approaches $(0, 0, 1)$, since $g \rightarrow \infty$. ♦

The representation in Theorem 7 is not unique, because there are many different conformal maps $\Phi: V \rightarrow M$. If $\Phi_i: V_i \rightarrow M$ are two conformal maps, then the map

$$\alpha = \Phi_2^{-1} \circ \Phi_1: U \rightarrow \mathbb{R}^2 \quad U = \Phi_1^{-1}(\Phi_2(V_2)),$$

from the open set $U \subset \mathbb{R}^2$ into \mathbb{R}^2 , is conformal with respect to the usual Riemannian metric on \mathbb{R}^2 . It is easy to see (Problem 4-9) that such conformal maps α are precisely the one-one complex analytic maps α and their conjugates. Conversely, if we are given $\Phi_{(f,g)}: V \rightarrow M$ in Theorem 7, and a one-one analytic or conjugate analytic map $\alpha: W \rightarrow V$, then $\Phi_{(f,g)} \circ \alpha: W \rightarrow M$ is another conformal map into the same minimal surface, and it must have the same form, with different f and g . One can obtain the new f and g by making the substitution $w = \alpha(u)$ in the integrals of Theorem 7.

The non-uniqueness in Theorem 7 is not really much of a problem, for we have already seen that there is practically a canonical way to select a conformal map $\Phi: V \rightarrow M$ which covers a given point p of an imbedded minimal surface $M \subset \mathbb{R}^3$. We only have to assume that p is not a flat point, and also that $v(p) \neq (0, 0, 1) \in S^2$. Then $v(U) \subset S^2 - \{(0, 0, 1)\}$ for some neighborhood U of p , and $\sigma \circ v: U \rightarrow V \subset \mathbb{C}$ is conformal, where $\sigma: S^2 - \{(0, 0, 1)\} \rightarrow \mathbb{C}$ is stereographic projection. Hence we can choose $v^{-1} \circ \sigma^{-1}: V \rightarrow \mathbb{R}^3$ as our conformal map, and Theorem 7 shows that there are f and g with

$$v^{-1} \circ \sigma^{-1} = \Phi_{(f,g)}, \quad \text{or} \quad N = v \circ \Phi_{(f,g)} = \sigma^{-1}.$$

But the formula in Proposition 8, together with the formula for σ^{-1} on page 265, shows that $N = \sigma^{-1}$ precisely when $g(z) = z$ for all z . We therefore have a representation of M in the following form (traditionally written with omission of the constants c_i):

$$\begin{aligned} \Phi^1 &= \operatorname{Re} \int \frac{1}{2} F(w)(1 - w^2) dw \\ (*) \quad \Phi^2 &= \operatorname{Re} \int \frac{i}{2} F(w)(1 + w^2) dw \quad (F \text{ nowhere } 0). \\ \Phi^3 &= \operatorname{Re} \int F(w)w dw \end{aligned}$$

We could also have obtained this representation in a different way, by beginning with the formulas for $\Phi_{(f,g)}$ in Theorem 7 and then making the substitution $w = g^{-1}(u)$; in other words, we could find the formulas for $\Phi_{(f,g)} \circ g^{-1}$. Notice that a local inverse g^{-1} exists around z precisely when z is not a pole of g and $g'(z) \neq 0$; the first condition is equivalent to $v(\Phi(z)) \neq (0, 0, 1)$, and it is easy to see that the second condition is equivalent to v_* being one-one at $\Phi(z)$.

The representation $(*)$ is especially nice to work with. Problem 1 gives the choices of F which lead to the helicoid, the catenoid, and Scherk's minimal surface; if we take the simplest case of all, $F(w) = 1$, we obtain Enneper's surface, which seemed so mysterious when it was first introduced in Chapter 3. Naturally, the geometric information given by Proposition 8 now simplifies considerably. If Φ_F is given by $(*)$, then

$$\begin{aligned} N &= v \circ \Phi_F = \sigma^{-1} \\ (**) \quad \Phi_F^* \langle \cdot, \cdot \rangle &= \mu(dx \otimes dx + dy \otimes dy), \\ \text{where } \mu(z) &= \frac{|F(z)|^2(1 + |z|^2)^2}{4}. \end{aligned}$$

Notice in particular, that for real θ , the minimal surfaces $\Phi = \Phi_{e^{-i\theta}F}$,

$$\Phi^1 = \operatorname{Re} e^{-i\theta} \int \frac{1}{2} F(w)(1 - w^2) dw$$

$$\Phi^2 = \operatorname{Re} e^{-i\theta} \int \frac{i}{2} F(w)(1 + w^2) dw$$

$$\Phi^3 = \operatorname{Re} e^{-i\theta} \int F(w)w dw,$$

are all locally *isometric*, the isometry being given by

$$\Phi_{e^{-i\theta}F}(z) \mapsto \Phi_{e^{-i\phi}F}(z).$$

In general, we call two connected minimal surfaces **associated** if they have this representation for the same F and real θ and ϕ . It suffices to have this for some small piece of each surface, since minimal surfaces are analytic. We also define two planes to be associated surfaces (these are the only minimal surfaces where the representation $(*)$ cannot be achieved [except at isolated points]). Associated minimal surfaces are not only locally isometric, but can also clearly be made part of a continuous family of isometric surfaces. With the proper choice of F we obtain (Problem 1) the continuous family of isometric surfaces between the catenoid and helicoid which is pictured on pg. III.171.

On first consideration, it seems to be a pure stroke of luck that the catenoid and helicoid are not only isometric, but also associated. However, there's definitely more to it than that:

9. THEOREM (H. SCHWARZ). If two minimal surfaces are isometric, then one of them is congruent to an associated surface of the other.

PROOF. If one of the surfaces is a plane, the other must be also; for $H = 0$ and $K = 0$ implies that both principal curvatures are 0. So we will assume neither is a plane. We can then represent them as

$$\begin{aligned} f &= \Phi_F: V \rightarrow \mathbb{R}^3 \\ g &= \Phi_G: W \rightarrow \mathbb{R}^3. \end{aligned}$$

By hypothesis, there is a map $\alpha: V \rightarrow W$ such that the correspondence $\Phi_F(z) \mapsto \Phi_G(\alpha(z))$ is an isometry. We want to show that after changing the second minimal surface by a congruence we will actually have $\alpha = \text{identity}$. Then relations $(**)$ will show that $|F(z)| = |G(z)|$, and the maximum modulus principle applied to G/F will imply that we have $G = e^{-i\theta} F$ for some real θ .

The third fundamental form will play a role. Since the surfaces f and $g \circ \alpha$ are minimal, Proposition 2-6 gives

$$\begin{aligned} \text{III}_f &= -(K \circ f)I_f \\ \text{III}_{g \circ \alpha} &= -(K \circ g \circ \alpha)I_{g \circ \alpha}. \end{aligned}$$

On the other hand, $I_f = I_{g \circ \alpha}$ by hypothesis, and therefore $K \circ f = K \circ g \circ \alpha$ by the Theorema Egregium. So

$$\text{III}_f = \text{III}_{g \circ \alpha}.$$

But by Proposition 2-7 we have

$$\begin{aligned} \text{III}_f &= I_{N_1} = -\text{II}_{N_1} & N_1 &= \text{normal map of } f \\ \text{III}_{g \circ \alpha} &= I_{N_2} = -\text{II}_{N_2} & N_2 &= \text{normal map of } g \circ \alpha. \end{aligned}$$

We thus find that

$$I_{N_1} = I_{N_2} \quad \text{and} \quad \text{II}_{N_1} = \text{II}_{N_2}.$$

The Fundamental Theorem of Surface Theory then implies that N_1 and N_2 are the same up to a congruence. So if we change our second surface by a congruence we can assume that $N_1 = N_2$. But then (**) gives

$$\sigma^{-1}(z) = \sigma^{-1}(\alpha(z)).$$

So we must have $\alpha(z) = z$. ♦

We conclude with one curious phenomenon concerning the representation (*). This representation was supposed to depend only on the imbedded minimal surface M , but this is not exactly the case, for it also depends on the choice of the normal map ν , or equivalently, on the choice of an orientation for M . So while ν gives rise to the map Φ_F with

$$(1) \quad \nu \circ \Phi_F = \sigma^{-1} \quad \text{defined on some } V \subset \mathbb{C},$$

the map $-\nu$ will give rise to a map $\Phi_{\tilde{F}}$ with

$$(2) \quad -\nu \circ \Phi_{\tilde{F}} = \sigma^{-1} \quad \text{defined on some } W \subset \mathbb{C}.$$

Since Φ_F and $\Phi_{\tilde{F}}$ are conformal maps into M , inducing opposite orientations, there must be a conjugate analytic map $\alpha: W \rightarrow V$ such that

$$(3) \quad \Phi_F(z) = \Phi_{\tilde{F}}(\alpha(z)) \quad z \in W.$$

This means that for all $z \in W$ we have

$$\begin{aligned}\sigma^{-1}(\alpha(z)) &= -v(\Phi_{\tilde{F}}(\alpha(z))) && \text{by (2)} \\ &= -v(\phi_F(z)) && \text{by (3)} \\ &= -\sigma^{-1}(z) && \text{by (1).}\end{aligned}$$

Thus we must have

$$\begin{aligned}\alpha(z) &= \sigma(-\sigma^{-1}(z)) \\ &= -\frac{1}{\bar{z}}.\end{aligned}$$

Writing equation (3) in terms of (*), we thus obtain

$$\begin{aligned}\operatorname{Re} \int^z F(w)(1-w^2) dw (+ \text{constant}) &= \operatorname{Re} \int^{-1/\bar{z}} \tilde{F}(w)(1-w^2) dw \\ &= \operatorname{Re} \left(\overline{\int^{-1/\bar{z}} \tilde{F}(w)(1-w^2) dw} \right) \\ &= \operatorname{Re} \int^{-1/z} \overline{\tilde{F}(\bar{w})(1-\bar{w}^2)} dw \\ &= \operatorname{Re} \int^{-1/z} \overline{\tilde{F}(\bar{w})} (1-w^2) dw,\end{aligned}$$

which, using substitution, yields

$$\operatorname{Re} \int^z F(w)(1-w^2) dw (+ \text{constant}) = \operatorname{Re} \int^z \overline{\tilde{F}\left(-\frac{1}{\bar{w}}\right)} \left(1 - \frac{1}{w^2} \frac{1}{\bar{w}^2}\right) dw.$$

We obtain two other equations in a similar way, but, as one would certainly hope, these equations all lead to the same relation:

$$\tilde{F}(z) = -\frac{1}{z^4} \overline{F\left(-\frac{1}{\bar{z}}\right)}.$$

This \tilde{F} gives the exact same surface as F , but it induces the opposite orientation on M .

Now the interesting thing is, that there are functions F which equal \tilde{F} , the simplest example being

$$F(z) = 1 - \frac{1}{z^4} = \frac{z^4 - 1}{z^4}.$$

This choice of F leads to **Henneberg's minimal surface**

$$\Phi^1 = \operatorname{Re} \int \frac{1}{2} \frac{w^4 - 1}{w^4} (1 - w^2) dw$$

$$\Phi^2 = \operatorname{Re} \int \frac{i}{2} \frac{w^4 - 1}{w^4} (1 + w^2) dw$$

$$\Phi^3 = \operatorname{Re} \int \frac{w^4 - 1}{w^3} dw.$$

The map Φ can be defined on all of $\mathbb{C} - \{0\}$ (we don't even have to restrict ourselves to a simply-connected domain, since all integrands have residue 0 at 0, so the integrals are independent of the path); however, Φ is not an immersion at $\pm 1, \pm i$, the points where F is zero. Using stereographic projection, we can identify $\mathbb{C} - \{0, \pm 1, \pm i\}$ with S^2 minus three pairs of antipodal points, the points $\pm 1, \pm i$ occurring on the equator of S^2 . Since

$$\Phi_F(z) = \Phi_{\tilde{F}}(\alpha(z)) = \Phi_{\tilde{F}}(\sigma(-\sigma^{-1}(z))) = \Phi_F(\sigma(-\sigma^{-1}(z))),$$

the map $\Phi_F \circ \sigma^{-1}: S^2 \rightarrow \mathbb{R}^3$ is invariant under the antipodal map, so our surface is the image of the projective plane punctured at three points. The figure below shows the image of a symmetric strip around the equator of S^2 .

The equator maps onto the vertical segment AB , with the pair of points corresponding to $\pm i$ mapping onto the upper endpoint, and the pair ± 1 onto the lower. The boundary circles of the strip each map into the closed curve which

intersects itself at points P_1, \dots, P_4 . The points of the segment AB are all double points of the immersion, but the surface crosses itself in a funny way along this line—it contains two congruent helicoid-like surfaces, with AB common to both.

The final figure below shows an imbedded Möbius strip lying inside the immersed surface.

Physicists, by the way, would not be surprised to learn that there are minimal surfaces in the shape of a Möbius strip. If one dips an appropriately bent piece

of wire into a soap solution, then a soap film will be formed in the shape of this surface (actually, one always obtains the sort of film pictured on the left; after the middle sheet is pierced, the soap film snaps back into the Möbius strip). If

one neglects the slight effect of gravity, then any soap film ought to be a minimal surface, since the surface tension makes the film contract as much as possible.

Considerations of this sort were first introduced by the blind experimental physicist Plateau, who gave a much more elaborate discussion of the problem, taking into account the thickness of the films. His writings gave rise to the **Plateau problem**, to prove that every imbedded circle in \mathbb{R}^3 is the boundary of an immersed disc which has minimum area among all such immersed discs; this very difficult problem was first solved by Jesse Douglas and Tibor Rado. Douglas' methods work just as well for higher dimensions, and his work won him the Field's medal in 1936. We will not even enter into a discussion of this work, which is almost purely analytic in nature, but descriptions of the methods used may be found in several references in the bibliography. There are many questions related to Plateau's problem, some of which have led to the invention of powerful new techniques. Notice, for example, that Plateau's problem is in some ways not even the natural question to ask, since it is concerned only with surfaces homeomorphic to a disc. Thus the solution of the Plateau problem for the curve pictured above will not be the Möbius strip, but a surface like the one shown below. Probably the simplest way to picture this surface is to make a piece

of wire in the right shape and dip it into a bubble solution (the two loops should be rather further apart than in the previous picture). It is fairly easy to find a shape that gives both a Möbius strip and a disc, depending on how it is dipped in. Since the two different soap films have unequal areas, this shows us that we should slightly revise our criterion for the shape of a soap film spanned by a given wire loop. The film need not have a minimum area—a local minimum should suffice. A surface which is a critical value, but not a local minimum, would presumably correspond to a position of unstable equilibrium—the slightest disturbance would cause the soap film to change shape; presumably such films could never occur in practice (in addition, of course, all sorts of physical considerations might rule out other surfaces on practical grounds).

If the wire loop is equipped with a pair of handles, then by gently pulling the two parts of the loop apart one can see the film jump from a Möbius strip to a disc, presumably at the point where the Möbius strip is no longer in stable equilibrium. Even for those who are willing to get involved in all the analysis necessary for the Plateau problem, experiments like this can be as instructive as they are fascinating, and provide convincing evidence for assertions that are still not mathematically provable; the interested reader should consult Courant [1]. And even if you are not eager to get your hands all soaped up, there is one description of simple experiments that you simply cannot afford to miss. This is a series of lectures by Boys [1] which treats soap films and soap bubbles, the mathematical correlates of which we will study a little later on. They were given to an audience of children in the good old Victorian days, and are among the best science writing ever produced. I seriously suggest that you put down the silly stuff you are presently reading, rush right out to purchase Boys' little gem of a book, and get high on physics for a while.

* * *

Returning to purely mathematical questions, we now seek a formula for the variation of area when we are dealing with an arbitrary variation of an immersed surface $f: M \rightarrow N$, in a general Riemannian manifold $(N, \langle \cdot, \cdot \rangle)$. We would even like to find the variation of n -dimensional volume for an immersion $f: M^n \rightarrow N^m$ (but at least we will not worry about maps and variations which are only piecewise C^∞). As a start in this direction, we consider a simple general problem from the classical calculus of variations in several variables. Suppose we are given a (suitably differentiable) function

$$F: \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^n \rightarrow \mathbb{R}$$

and a compact n -dimensional manifold-with-boundary $D \subset \mathbb{R}^n$. We seek, among all functions $g: D \rightarrow \mathbb{R}$ with prescribed values on ∂D , one which will

maximize (or minimize) the quantity

$$\begin{aligned}
 J(g) &= \int_D F(t_1, \dots, t_n, g(t_1, \dots, t_n), D_1 g(t_1, \dots, t_n), \dots, D_n g(t_1, \dots, t_n)) dt_1 \dots dt_n \\
 &= \int_D F(t, g(t), Dg(t)) dt_1 \dots dt_n, \quad \text{in abbreviated form.}
 \end{aligned}$$

This is a direct generalization of the problem considered on pg. I.316. For any variation $\alpha: (-\varepsilon, \varepsilon) \times D \rightarrow \mathbb{R}$ of g , we compute the variation of J as follows. It will be convenient to denote a typical point in the domain of F by

$$(t_1, \dots, t_n, x, y_1, \dots, y_n) \quad \text{or, even more briefly, by} \quad (t, x, y).$$

Then

$$\begin{aligned}
 \left. \frac{dJ(\bar{\alpha}(u))}{du} \right|_{u=0} &= \left. \frac{d}{du} \right|_{u=0} \int_D F \left(t, \alpha(u, t), \frac{\partial \alpha}{\partial t}(u, t) \right) dt_1 \dots dt_n \\
 &\quad \left(\frac{\partial \alpha}{\partial t} \text{ stands for } \frac{\partial \alpha}{\partial t_1}, \dots, \frac{\partial \alpha}{\partial t_n} \right) \\
 &= \int_D \left[\left. \frac{d}{du} \right|_{u=0} F(t, \alpha(u, t), \frac{\partial \alpha}{\partial t}(u, t)) \right] dt_1 \dots dt_n \\
 &= \int_D \left[\frac{\partial \alpha}{\partial u}(0, t) \cdot \frac{\partial F}{\partial x}(\bullet) + \sum_{i=1}^n \frac{\partial^2 \alpha}{\partial u \partial t_i}(0, t) \cdot \frac{\partial F}{\partial y_i}(\bullet) \right] dt_1 \dots dt_n,
 \end{aligned}$$

where

$$(1) \quad \bullet = \left(t_1, \dots, t_n, g(t_1, \dots, t_n), \frac{\partial g}{\partial t_1}(t_1, \dots, t_n), \dots, \frac{\partial g}{\partial t_n}(t_1, \dots, t_n) \right).$$

Introducing the abbreviations

$$\begin{aligned}
 (2) \quad w(t) &= \frac{\partial \alpha}{\partial u}(0, t) \\
 A(t) &= \frac{\partial F}{\partial x}(\bullet) \quad (\text{all of these are functions on } D) \\
 B_i(t) &= \frac{\partial F}{\partial y_i}(\bullet).
 \end{aligned}$$

we can write

$$\left. \frac{dJ(\bar{\alpha}(u))}{du} \right|_{u=0} = \int_D \left[w \cdot A + \sum_{i=1}^n \frac{\partial w}{\partial t_i} \cdot B_i \right] dt_1 \wedge \dots \wedge dt_n.$$

We now have to pull an integration-by-parts-type trick on the second term in the integrand. We do this by considering the $(n-1)$ -form ϖ defined by

$$(3) \quad \varpi = \sum_{i=1}^n (-1)^{i+1} (w \cdot B_i) dt_1 \wedge \cdots \wedge \widehat{dt_i} \wedge \cdots \wedge dt_n.$$

Since

$$d\varpi = \left[w \cdot \sum_{i=1}^n \frac{\partial B_i}{\partial t_i} \right] dt_1 \wedge \cdots \wedge dt_n + \left[\sum_{i=1}^n \frac{\partial w}{\partial t_i} B_i \right] dt_1 \wedge \cdots \wedge dt_n,$$

we have

$$\begin{aligned} \frac{dJ(\bar{\alpha}(u))}{du} \Big|_{u=0} &= \int_D \left[w \cdot \left(A - \sum_{i=1}^n \frac{\partial B_i}{\partial t_i} \right) \right] dt_1 \wedge \cdots \wedge dt_n + \int_D d\varpi \\ &= \int_D \left[w \cdot \left(A - \sum_{i=1}^n \frac{\partial B_i}{\partial t_i} \right) \right] dt_1 \wedge \cdots \wedge dt_n + \int_{\partial D} \varpi. \end{aligned}$$

From the definition of ϖ , we see that $\varpi = 0$ on ∂D if α is a variation keeping the boundary fixed. So g is a critical point for J if and only if

$$0 = \frac{dJ(\bar{\alpha}(u))}{du} \Big|_{u=0} = \int_D \left[\frac{\partial \alpha}{\partial u}(0, t) \cdot \left(A - \sum_{i=1}^n \frac{\partial B_i}{\partial t_i} \right) \right] dt_1 \wedge \cdots \wedge dt_n$$

for all variations α keeping the boundary fixed. From this we easily see that g must satisfy the equation

$$A - \sum_{i=1}^n \frac{\partial B_i}{\partial t_i} = 0,$$

that is,

$$(*) \quad \frac{\partial F}{\partial x}(\bullet) - \sum_{i=1}^n \frac{\partial^2 F}{\partial t_i \partial y_i}(\bullet) = 0, \quad \text{where } \bullet \text{ is given by (1).}$$

This is the classical analogue of Euler's equation (Theorem I.9-8).

As a particular example, we take $n = 2$, and let

$$(4) \quad F(t_1, t_2, x, y_1, y_2) = \sqrt{1 + y_1^2 + y_2^2}.$$

so that

$$\begin{aligned} J(g) &= \int_D \sqrt{1 + g_1^2 + g_2^2} \, dt_1 \, dt_2 \quad \left(g_i = \frac{\partial g}{\partial t_i} \right) \\ &= \int_D \sqrt{EG - F^2} \, dt_1 \, dt_2 \quad \text{by formulas (A') on pg. III.137.} \end{aligned}$$

Thus $J(g)$ is the area of the imbedded surface

$$f(t_1, t_2) = (t_1, t_2, g(t_1, t_2)).$$

A variation $\alpha: (-\varepsilon, \varepsilon) \times D \rightarrow \mathbb{R}$ of g gives rise to a variation $\beta: (-\varepsilon, \varepsilon) \times D \rightarrow \mathbb{R}^3$ of the imbedding f , defined by

$$\beta(u, t_1, t_2) = (t_1, t_2, \alpha(u, t_1, t_2)).$$

This variation β is perpendicular to the (t_1, t_2) -plane, instead of being perpendicular to the surface $M = f(D)$; it has variation vector

$$W(t_1, t_2) = (0, 0, w(t_1, t_2))_{f(t_1, t_2)}.$$

This is the one other kind of variation sometimes encountered in differential geometry books, and the kind which is always used in books on the calculus of variations. Indeed, this particular example was chosen by Lagrange to illustrate the general methods which he had developed (1760) for the calculus of variations in several variables. In this case, equation (4) gives

$$\frac{\partial F}{\partial x} = 0, \quad \frac{\partial F}{\partial y_i} = \frac{y_i}{\sqrt{1 + y_1^2 + y_2^2}}.$$

so equation (*) becomes

$$\frac{\partial}{\partial t_1} \left(\frac{g_1}{R} \right) + \frac{\partial}{\partial t_2} \left(\frac{g_2}{R} \right) = 0, \quad R = \sqrt{1 + g_1^2 + g_2^2},$$

which boils down to exactly the equation

$$(1 + g_1^2)g_{11} - 2g_1g_2g_{12} + (1 + g_2^2)g_{22} = 0$$

which we found in the proof of Proposition 3; it was only in 1776 that Meusnier interpreted this equation in terms of the mean curvature of f .

We will also be interested in the 1-form ϖ which we obtain in this case; from (2) and (3) we see that

$$\varpi = \frac{w \cdot g_1}{R} dt_2 - \frac{w \cdot g_2}{R} dt_1.$$

We will express ϖ in terms of the form ω on $M = f(D)$ with $\varpi = f^*\omega$. We have

$$\begin{aligned} \omega((1, 0, g_1)) &= \varpi \left(f_* \left(\frac{\partial}{\partial t_1} \right) \right) = \left\langle (1, 0, g_1), \left(-\frac{w \cdot g_2}{R}, -\frac{w \cdot g_1}{R}, 0 \right) \right\rangle \\ \omega((0, 1, g_2)) &= \varpi \left(f_* \left(\frac{\partial}{\partial t_2} \right) \right) = \left\langle (0, 1, g_2), \left(-\frac{w \cdot g_2}{R}, -\frac{w \cdot g_1}{R}, 0 \right) \right\rangle. \end{aligned}$$

But

$$\begin{aligned} \left(-\frac{w \cdot g_2}{R}, -\frac{w \cdot g_1}{R}, 0 \right) &= \left(-\frac{g_1}{R}, -\frac{g_2}{R}, \frac{1}{R} \right) \times (0, 0, w) \\ &= v \times W, \end{aligned}$$

where v is the normal vector. So for all $X \in M_p$ we have

$$\begin{aligned} \omega(p)(X) &= \langle v(p) \times W(p), X \rangle \\ &= \langle W(p) \times X, v(p) \rangle \\ &= \langle \mathbb{T}W(p) \times X, v(p) \rangle, \quad \mathbb{T}W(p) = \text{tangential component of } W(p). \end{aligned}$$

If dA is the 2-dimensional volume form on M , then we have

$$\omega(X) = dA(\mathbb{T}W, X).$$

Using the notation introduced on pg. I.227, we can thus write

$$\omega = \mathbb{T}W \lrcorner dA.$$

Without going through the calculations, we merely state that if we take an arbitrary n and let

$$F(t_1, \dots, t_n, x, y_1, \dots, y_n) = \sqrt{1 + \sum_i y_i^2},$$

so that $J(g)$ represents the n -dimensional volume of the imbedded n -manifold $\{f(t_1, \dots, t_n, g(t_1, \dots, t_n))\}$, then the $(n-1)$ -form ϖ is $f^*\omega$, where the $(n-1)$ -form ω on M is defined by

$$\omega = \mathbb{T}W \lrcorner dV \quad dV = \text{volume element on } M.$$

This $(n-1)$ -form ω will be very important when we look for an invariant description of the variation of n -dimensional volume for an immersion $f: M^n \rightarrow N$. We have always expressed length or area as an integral involving a coordinate system, and calculated the derivative with respect to the variation parameter u by using “Leibniz’ Rule” to bring the derivative inside the integral sign. Before we go any further, we will need an invariant description of this procedure.

Suppose we have a C^∞ 1-parameter family of k -forms on an n -manifold (-with-boundary) M ; thus, for each $u \in (-\varepsilon, \varepsilon)$, we have a k -form $\Gamma(u)$ on M . For each $p \in M$, the map $u \mapsto \Gamma(u)(p) \in \Omega^k(M_p)$ into the vector space $\Omega^k(M_p)$ then has a derivative, which at each u is again an element $\dot{\Gamma}(u)(p) \in \Omega^k(M_p)$. Thus a C^∞ 1-parameter family of k -forms $u \mapsto \Gamma(u)$ on M gives rise to a new C^∞ 1-parameter family of k -forms $u \mapsto \dot{\Gamma}(u)$ on M .

10. PROPOSITION (LEIBNIZ’ RULE). Let M be a compact oriented n -dimensional manifold-with-boundary and $u \mapsto \Gamma(u)$ a C^∞ 1-parameter family of n -forms on M . Then

$$\left. \frac{d}{du} \right|_{u=u_0} \int_M \Gamma(u) = \int_M \dot{\Gamma}(u_0).$$

PROOF. Let \mathcal{O} be a finite cover of M by open sets V each contained in $c([0, 1]^n)$ for some orientation preserving singular n -cube $c: [0, 1]^n \rightarrow M$. Let $\Phi = \{\phi_V\}$ be a partition of unity subordinate to this cover. Then

$$\int_M \phi_V \cdot \Gamma(u) = \int_{[0, 1]^n} (\phi_V \circ c) \cdot c^* \Gamma(u).$$

It is easy to see that the ordinary Leibniz' Rule implies that

$$\left. \frac{d}{du} \right|_{u=u_0} \int_M \phi_V \cdot \Gamma(u) = \int_{[0,1]^n} (\phi_V \circ c) \cdot c^* \dot{\Gamma}(u_0) = \int_M \phi_V \dot{\Gamma}(u_0).$$

Since

$$\int_M \Gamma(u) = \sum_{\{\phi_V\}} \int_M \phi_V \cdot \Gamma(u),$$

and similarly for $\int_M \dot{\Gamma}(u_0)$, the result follows. \blacklozenge

Now consider a compact oriented n -dimensional manifold-with-boundary M , and a C^∞ map $\alpha: (-\varepsilon, \varepsilon) \times M \rightarrow N$, where $(N, \langle \cdot, \cdot \rangle)$ is a Riemannian manifold. We will assume that each $\bar{\alpha}(u): M \rightarrow N$ is an immersion. Then the metric $\bar{\alpha}(u)^* \langle \cdot, \cdot \rangle$ on M determines a volume element $\Gamma(u)$ on M ; using the given orientation of M , we can consider this to be an n -form on M , which we call the **volume form**. What we want to determine is

$$\left. \frac{d}{du} \right|_{u=0} \int_M \Gamma(u).$$

According to Proposition 10, it suffices to determine $\dot{\Gamma}(0)$. For this we do not even need M to be compact.

11. THEOREM (VARIATION OF VOLUME FORMULA). Let $f: M \rightarrow N$ be an immersion of an oriented n -dimensional manifold (-with-boundary) M into a Riemannian manifold $(N^m, \langle \cdot, \cdot \rangle)$ and let $\alpha: (-\varepsilon, \varepsilon) \times M \rightarrow N$ be a variation of f through immersions, with variation vector field W . If $\Gamma(u)$ is the volume form of M determined by the metric $\bar{\alpha}(u)^* \langle \cdot, \cdot \rangle$ and the given orientation of M , then

$$\dot{\Gamma}(0) = -\langle W, n \cdot \eta \rangle \cdot \Gamma(0) + d(\top W \lrcorner \Gamma(0))$$

where η is the mean curvature normal of the immersion f . [Notice that there is a slight abuse of notation here; at each $p \in M$, the vector $\top W$ really denotes the unique vector $X \in M_p$ with $f_*(X) = \top W$ at $f(p)$.]

PROOF. The theorem involves two n -forms on M which we have to prove are equal at all points of M . Let us first consider a point $p_0 \in M$ where $W(p_0)$ is not tangent to $f(M)$. By choosing a sufficiently small neighborhood V of p_0 ,

and decreasing ε if necessary, we can then assume that $\alpha: (-\varepsilon, \varepsilon) \times V \rightarrow N$ is an imbedding.

It will be convenient to identify V with $f(V)$, so that $f = \bar{\alpha}(0)$ is just the inclusion map $i: V \rightarrow N$. On some open set containing image α , we can choose an orthonormal moving frame $X_1, \dots, X_n, X_{n+1}, \dots, X_m$ such that

- (1) $X_j(\alpha(u, p))$ is tangent to the submanifold $\bar{\alpha}(u)(V)$ $1 \leq j \leq n$
- (2) $X_r(\alpha(u, p))$ is normal to the submanifold $\bar{\alpha}(u)(V)$ $n+1 \leq r \leq m$.

If $\phi^1, \dots, \phi^n, \phi^{n+1}, \dots, \phi^m$ are the dual 1-forms, then clearly

- (1') $\bar{\alpha}(u)^*(\phi^1 \wedge \dots \wedge \phi^n) = \Gamma(u)$
- (2') $\bar{\alpha}(u)^*(\phi^r) = 0 \quad n+1 \leq r \leq m$.

Now the variation vector field W , defined along V , is the restriction of the vector field $\tilde{W} = \partial\alpha/\partial u$ defined along all of image α . We can further extend \tilde{W} to a vector field defined on some open set containing image α ; we will use the same symbol \tilde{W} for this extension. Associated to this vector field \tilde{W} is a certain local 1-parameter group of local diffeomorphisms $\{\rho_u\}$; recall (Chapter I.5) that $\rho_u(q)$ is the result of following for time u the integral curve of \tilde{W} that starts at q . Clearly the integral curve of \tilde{W} that starts at a point $p \in V$ is just $u \mapsto \alpha(u, p)$. So

$$\rho_u(p) = \alpha(u, p) = \bar{\alpha}(u)(p), \quad p \in V.$$

It is therefore clear that if Y is a tangent vector of V , then

$$(3) \quad \rho_{u*}(i_*Y) = \bar{\alpha}(u)_*(Y).$$

Now let us recall the Lie derivative (pp. I.150, 174, 234): if ω is a k -form on N , then $L_{\tilde{W}}\omega$ is another k -form defined by

$$L_{\tilde{W}}\omega(Z_1, \dots, Z_k) = \lim_{h \rightarrow 0} \frac{1}{h} [\omega(\rho_{h*}Z_1, \dots, \rho_{h*}Z_k) - \omega(Z_1, \dots, Z_k)].$$

We claim that

$$(4) \quad \dot{\Gamma}(0) = i^*\{L_{\tilde{W}}(\phi^1 \wedge \dots \wedge \phi^n)\}.$$

The proof of this will be quite straightforward. We adopt the abbreviation $\Phi = \phi^1 \wedge \dots \wedge \phi^n$. If Y_1, \dots, Y_n are tangent vectors of V , then we have

$$\begin{aligned} \dot{\Gamma}(0)(Y_1, \dots, Y_n) &= \lim_{h \rightarrow 0} \frac{1}{h} [\Gamma(h)(Y_1, \dots, Y_n) - \Gamma(0)(Y_1, \dots, Y_n)] \\ &= \lim_{h \rightarrow 0} \frac{1}{h} [\bar{\alpha}(h)^*\Phi(Y_1, \dots, Y_n) - i^*\Phi(Y_1, \dots, Y_n)] \quad \text{by (1')} \\ &= \lim_{h \rightarrow 0} \frac{1}{h} [\Phi(\bar{\alpha}(h)_*Y_1, \dots, \bar{\alpha}(h)_*Y_n) - \Phi(i_*Y_1, \dots, i_*Y_n)] \\ &= \lim_{h \rightarrow 0} \frac{1}{h} [\Phi(\rho_{h*}i_*Y_1, \dots, \rho_{h*}i_*Y_n) - \Phi(i_*Y_1, \dots, i_*Y_n)] \quad \text{by (3)} \\ &= L_{\tilde{W}}\Phi(i_*Y_1, \dots, i_*Y_n), \end{aligned}$$

which proves (4).

The reason for bringing in the Lie derivative is that we have some useful formulas for it. In particular (pg. I.235), we have

$$L_{\tilde{W}}\omega = \tilde{W} \lrcorner d\omega + d(\tilde{W} \lrcorner \omega).$$

Substituting this into (4) we obtain

$$(5) \quad \dot{\Gamma}(0) = i^*\{\tilde{W} \lrcorner d\Phi\} + d(i^*\{\tilde{W} \lrcorner \Phi\}).$$

We will show that the two terms on the right are precisely the terms appearing in the statement of the theorem.

We first compute $d\Phi = d(\phi^1 \wedge \dots \wedge \phi^n)$ by using the first structural equation for N , which will bring in the connection forms ψ_β^α ($1 \leq \alpha, \beta \leq m$) for N associated to ϕ^1, \dots, ϕ^m :

$$\begin{aligned} (6) \quad d\Phi &= d(\phi^1 \wedge \dots \wedge \phi^n) = \sum_{j=1}^n (-1)^{j+1} \phi^1 \wedge \dots \wedge d\phi^j \wedge \dots \wedge \phi^n \\ &= \sum_{j=1}^n (-1)^{j+1} \phi^1 \wedge \dots \wedge \left(- \sum_{\alpha=1}^m \psi_\alpha^j \wedge \phi^\alpha \right) \wedge \dots \wedge \phi^n \\ &= \sum_{j=1}^n \sum_{r=n+1}^m \phi^r \wedge \phi^1 \wedge \dots \wedge \psi_r^j \wedge \dots \wedge \phi^n. \end{aligned}$$

So if Y_1, \dots, Y_n are the tangent vectors of V with $i_* Y_j = X_j$ along V , then

$$\begin{aligned}
 (7) \quad i^*\{\tilde{W} \lrcorner d\Phi\}(Y_1, \dots, Y_n) &= d\Phi(W, X_1, \dots, X_n) \\
 &= \sum_{j=1}^n \sum_{r=n+1}^m (\phi^r \wedge \phi^1 \wedge \dots \wedge \psi_r^j \wedge \dots \wedge \phi^n)(W, X_1, \dots, X_n) \\
 &= \sum_{j=1}^n \sum_{r=n+1}^m \phi^r(W) \psi_r^j(X_j),
 \end{aligned}$$

since (2') says that $\phi^r(X_j) = 0$ for $i \leq n < r$. On the other hand, we have

$$\nabla'_{X_j} X_j = \sum_{\alpha=1}^m \psi_j^\alpha(X_j) \cdot X_\alpha = - \sum_{\alpha=1}^m \psi_\alpha^j(X_j) \cdot X_\alpha,$$

so

$$n \cdot \eta = \perp \left(\sum_{j=1}^n \nabla'_{X_j} X_j \right) = \sum_{j=1}^n \left(- \sum_{r=n+1}^m \psi_r^j(X_j) X_r \right),$$

and hence

$$(8) \quad -\langle W, n \cdot \eta \rangle = \sum_{j=1}^n \sum_{r=n+1}^m \phi^r(W) \psi_r^j(X_j).$$

Equations (7) and (8) thus give

$$(9) \quad i^*\{\tilde{W} \lrcorner d\Phi\} = -\langle W, n \cdot \eta \rangle \cdot \Gamma(0).$$

As for the other term in (5), if Y_1, \dots, Y_{n-1} are tangent vectors of V , then we have

$$\begin{aligned}
 i^*\{\tilde{W} \lrcorner \Phi\}(Y_1, \dots, Y_{n-1}) &= \Phi(W, i_* Y_1, \dots, i_* Y_{n-1}) \\
 &= (\phi^1 \wedge \dots \wedge \phi^n)(W, i_* Y_1, \dots, i_* Y_{n-1}) \\
 &= (\phi^1 \wedge \dots \wedge \phi^n)(\mathbb{T}W, i_* Y_1, \dots, i_* Y_{n-1}) \\
 &\quad \text{since each } \phi^j(\perp W) = 0 \\
 &= [\mathbb{T}W \lrcorner i^*(\phi^1 \wedge \dots \wedge \phi^n)](Y_1, \dots, Y_{n-1}).
 \end{aligned}$$

Thus

$$(10) \quad i^*\{\tilde{W} \lrcorner \Phi\} = \mathbb{T}W \lrcorner \Gamma(0).$$

This completes the proof of the theorem at any point p_0 where $W(p_0)$ is not tangent to $f(M)$.

The general case can be disposed of by a technical trick. Let $\mathbf{N} = N \times \mathbb{R}$, with the product Riemannian metric, which we also denote by $\langle \cdot, \cdot \rangle$, and define $\alpha: (-\varepsilon, \varepsilon) \times M \rightarrow \mathbf{N}$ by

$$\alpha(u, p) = (\alpha(u, p), u).$$

The new variation vector field \mathbf{W} is

$$\mathbf{W}(p) = (W(p), 1),$$

where 1 denotes the unit vector field on \mathbb{R} . Clearly \mathbf{W} is not tangent to $\bar{\alpha}(0)(M) \subset N \times \{0\}$, so the theorem holds for α . On the other hand, it is easy to see that the new mean curvature normal η is just

$$\eta(p) = (\eta, 0),$$

so that $\langle \mathbf{W}, \eta \rangle = \langle W, \eta \rangle$; thus the result for α implies the result for α . ♦

12. COROLLARY. Let $\alpha: (-\varepsilon, \varepsilon) \times M \rightarrow N$ be a variation of an immersion $f: M \rightarrow N$ of a compact oriented n -dimensional manifold-with-boundary M into a Riemannian manifold $(N, \langle \cdot, \cdot \rangle)$. If $V(\bar{\alpha}(u))$ is the n -dimensional volume of M determined by the metric $\bar{\alpha}(u)^*\langle \cdot, \cdot \rangle$ and the given orientation of M , then

$$\left. \frac{dV(\bar{\alpha}(u))}{du} \right|_{u=0} = - \int_M \langle W, n \cdot \eta \rangle dV + \int_{\partial M} \omega,$$

where dV is the volume element determined by $f^*\langle \cdot, \cdot \rangle$ and $\omega = W \lrcorner dV$. In particular, if α is a variation keeping ∂M fixed, then

$$\left. \frac{dV(\bar{\alpha}(u))}{du} \right|_{u=0} = - \int_M \langle W, n \cdot \eta \rangle dV.$$

The immersion f is a critical point for V , among all immersions $g: M \rightarrow N$ with $g = f$ on ∂M , if and only if $\eta = 0$ everywhere.

PROOF. The first statement follows from Theorem 11, Leibniz' Rule, and Stokes' Theorem. If α keeps ∂M fixed, then $W = 0$ on ∂M , so also $\omega = 0$ on ∂M ; this proves the second statement. To prove the third, we can choose $W = \phi \cdot \eta$, where ϕ is a C^∞ function on M which is 0 on ∂M and positive on $M - \partial M$. ♦

Notice that in the expression

$$- \int_M \langle W, n \cdot \eta \rangle dV + \int_{\partial M} \omega,$$

the first term depends only on the normal component $\mathbf{L}W$ of W ; for we have $\langle W, n \cdot \eta \rangle = \langle \mathbf{L}W, n \cdot \eta \rangle$, since η is perpendicular to $f(M)$. This partially confirms our suspicion that we need work only with normal variations. On the other hand, in the term $\int_{\partial M} \omega$, only the tangential component $\mathbf{T}W$ enters; roughly speaking, the integral measures how much the volume of M is changing because of the way that the variation is expanding its boundary. In particular, we see that $\int_{\partial M} \omega$ is 0 not only when the variation keeps the boundary fixed, but also when W is normal to M along the boundary. Consequently, if $\eta = 0$ on M , then $dV(\bar{\alpha}(u))/du|_{u=0}$ will be 0 for every variation which is perpendicular on the boundary of M , not merely for those variations which keep ∂M fixed. Back in our original equation (*) on page 262 we didn't have any term involving an integral over ∂D precisely because we were dealing only with normal variations. This leads to an interesting phenomenon in the case of minimal surfaces $M \subset \mathbb{R}^3$. If v is the unit normal vector on M , then we can define a variation α of the inclusion $i: M \rightarrow \mathbb{R}^3$ by

$$\alpha(u, p) = p + u \cdot v(p).$$

The various surfaces $\{\alpha(u, p) : p \in M\}$ are called the **parallel surfaces** of M .

Since this variation α has $W = v$, which is everywhere normal to M , we must have

$$\left. \frac{dA(\bar{\alpha}(u))}{du} \right|_{u=0} = 0.$$

But this equality does not necessarily mean that $A(\bar{\alpha}(0))$ is a minimum. Indeed, as Problem 3-12 shows, each parallel surface has *smaller* area than M , so actually $A(\bar{\alpha}(0))$ is a maximum! Something quite similar happens in the case of geodesics on a surface of positive curvature. For example, on S^2 , a portion

of a great circle is *longer* than a “parallel” curve. The phenomenon for minimum surfaces is analyzed in greater detail in Addendum 4, which considers the second variation of volume.

Although we have derived the fundamental formula for the variation of volume in all dimensions, we will not proceed to discuss the analogues of minimal surfaces in higher dimensions, except to say that this topic has generated much interest in recent years. We should also mention that the study of minimal hypersurfaces in spheres has also attracted much attention, and differs greatly from the theory for Euclidean spaces. For example (Lawson [I]), every compact orientable surface can be imbedded as a minimal surface in S^3 .

For the remainder of this chapter, we will discuss a few other topics involving the variation of volume. We will often digress quite a bit from purely differential-geometric matters, and unfortunately our remarks will not form a coherent subject like the study of minimal surfaces.

Two special cases of Corollary 12 will form the starting point of our considerations. Suppose first that M is simply a compact manifold with no boundary. Then we have

$$(I) \quad \left. \frac{dV(\bar{\alpha}(u))}{du} \right|_{u=0} = - \int_M \langle W, n \cdot \eta \rangle dV.$$

We can also apply Corollary 12 when M and N have the same dimension n , so that $M \subset N$ is a compact n -dimensional manifold-with-boundary in the n -dimensional manifold N . In this case, $M_p = N_p$ for all $p \in M$, so $\mathbf{T}: N_p \rightarrow M_p$ is the identity, while $\mathbf{\perp}: N_p \rightarrow N_p$ is the 0 map. Consequently, η is automatically 0, and we have only the boundary term left,

$$\left. \frac{dV(\bar{\alpha}(u))}{du} \right|_{u=0} = \int_{\partial M} \omega.$$

It is easily checked that this can be written

$$(II) \quad \left. \frac{dV(\bar{\alpha}(u))}{du} \right|_{u=0} = \int_{\partial M} \langle W, \nu \rangle dV_{n-1},$$

where ν is the outward pointing normal on ∂M and dV_{n-1} is the $(n-1)$ -dimensional volume element on ∂M . This formula is certainly reasonable, for when we move each point p on ∂M a distance $\phi(p)$ along $\nu(p)$, we add on a narrow band whose volume is approximately $\int_{\partial M} \phi dV_{n-1}$.

Both formulas (I) and (II) are important for a discussion of the **isoperimetric problem**. The classical isoperimetric problem was to find the curve of fixed length L which encloses the largest area; one naturally expects the answer to be a circle. One can also seek the curve of smallest length which encloses a fixed area; presumably the answer to this “dual” problem is also a circle. We should also mention the **problem of Dido**, to find the curve of fixed length between two points P and Q which, together with the straight line between P and Q , encloses the largest area; the expected answer is an arc of a circle. These classical problems have given rise to a whole class of problems in the calculus of variations, known generically as “isoperimetric problems”. To illustrate this sort of problem we will, for simplicity, stay in dimension 1. Consider two functions

$$F: \mathbb{R} \times \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R} \quad \text{and} \quad G: \mathbb{R} \times \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R}.$$

For a function $f: [a, b] \rightarrow \mathbb{R}$ we define

$$J(f) = \int_a^b F(t, f(t), f'(t)) dt$$

$$K(f) = \int_a^b G(t, f(t), f'(t)) dt.$$

Among all functions $f: [a, b] \rightarrow \mathbb{R}$ with fixed values at a and b , and a fixed value $J(f) = C$, we seek the one which maximizes or minimizes $K(f)$. The “dual” problem is to find that f with fixed values at a and b , and fixed $K(f) = C'$, which minimizes or maximizes $J(f)$. This problem is approached by generalizing the methods which work for the corresponding problem in ordinary calculus, a review of which is now in order.

Suppose we are given two differentiable functions $j, k: \mathbb{R}^n \rightarrow \mathbb{R}$, and we seek the maximum or minimum of j on the set $k^{-1}(C)$. The method of “Lagrangian

multipliers" states that if j attains its maximum or minimum on $k^{-1}(C)$ at the point p , and p is not a critical point of k , then there is a number λ such that

$$(1) \quad \frac{\partial j}{\partial x_i}(p) = \lambda \frac{\partial k}{\partial x_i}(p) \quad i = 1, \dots, n.$$

The proof of this assertion has already been outlined in Problem 3-3, but it is so crucial to the present discussion that it will be repeated here. We note that the hypotheses on k imply that in a neighborhood of p , the set $k^{-1}(C) \subset \mathbb{R}^n$ is a hypersurface M , and that $k_*(X_p) = 0$ for $X_p \in \mathbb{R}^n_p$ precisely when $X_p \in M_p$. Every such X_p is $c'(0)$ for some curve c in M . It follows that $j(c(t))$ has a

maximum or minimum at $t = 0$, which means that $j_*(X_p) = 0$. Thus the two linear functions $j_*, k_*: \mathbb{R}^n_p \rightarrow \mathbb{R}$ have the property that $\ker k_* \subset \ker j_*$. This implies that $j_* = \lambda k_*$ for some λ , which is equivalent to equation (1).

Notice that if k attains its maximum or minimum on $g^{-1}(C')$ at q , and q is not a critical point of j , then there is a number μ such that

$$(2) \quad \frac{\partial k}{\partial x_i}(q) = \mu \frac{\partial j}{\partial x_i}(q).$$

Equations (1) and (2) are equivalent, since $\lambda, \mu \neq 0$ (as p and q are not critical points). Thus, if p is a maximum point of g on $k^{-1}(C)$ and we set $C' = j(p)$, then p is at least one of the candidates for the minimum point of k on $j^{-1}(C')$. If we simply look for critical points for j on $k^{-1}(C)$ and for k on $j^{-1}(C')$, then these two "dual" problems are completely equivalent.

Let us apply these ideas to our two functions J and K . Suppose that the maximum or minimum of J on $K^{-1}(C)$ occurs at a C^2 function f which is not a critical point of K . Consider any variation $\alpha: (-\varepsilon, \varepsilon) \times [a, b] \rightarrow \mathbb{R}$ of f which keeps endpoints fixed. We know from formula (**) on pg. I.319 that $dJ(\bar{\alpha}(u))/du|_{u=0}$ depends only on the function $\partial\alpha/\partial u(0, t)$ on $[a, b]$. For any C^2 function W on $[a, b]$ with $W(a) = W(b) = 0$, we define

$$J_{f*}(W) = \frac{dJ(\bar{\alpha}(u))}{du} \Big|_{u=0} \quad \begin{array}{l} \text{for any variation } \alpha \text{ of } f \\ \text{with } \partial\alpha/\partial u(0, t) = W(t). \end{array}$$

Notice that there always is a variation α with this property, for example,

$$\alpha(u, t) = f(t) + uW(t).$$

The same W can be used to give a variation of any function f , so the “ f ” in the symbol $J_{f*}(W)$ is important. Nevertheless, since we will be considering only one f , we will usually write simply $J_*(W)$ for convenience. We define $K_*(W)$ in precisely the same way. We thus have functions $J_*, K_*: \mathcal{V} \rightarrow \mathbb{R}$, where \mathcal{V} is the vector space of all C^2 functions W on $[a, b]$ with $W(a) = W(b) = 0$. We claim that J_* (and likewise K_*) is linear. To see this we choose two variations α_1 and α_2 with

$$\frac{\partial \alpha_i}{\partial u}(0, t) = W_i(t),$$

and define the variation α by

$$\alpha(u, t) = \alpha_1(u, t) + \alpha_2(u, t).$$

Then

$$\frac{\partial \alpha}{\partial u}(0, t) = W_1(t) + W_2(t),$$

so

$$\begin{aligned} J_*(W_1 + W_2) &= \left. \frac{dJ(\bar{\alpha}(u))}{du} \right|_{u=0} \\ &= \left. \frac{dJ(\bar{\alpha}_1(u))}{du} \right|_{u=0} + \left. \frac{dJ(\bar{\alpha}_2(u))}{du} \right|_{u=0}, \\ &\quad \text{as one sees by inspecting formula (**) on pg. I.319,} \\ &= J_*(W_1) + J_*(W_2). \end{aligned}$$

Homogeneity is proved similarly.

We now make the following

CLAIM. If $K_*(W) = 0$, then $W = \partial \alpha / \partial u(0, t)$ for some variation α with the property that each $\bar{\alpha}(u)$ is in $K^{-1}(C)$.

Remember that, by hypothesis, f is *not* a critical point of K . From a modern point of view, our claim seems especially reasonable, for the set of all C^2 functions $\phi: [a, b] \rightarrow \mathbb{R}$, with given values at a and b , forms an infinite dimensional manifold, and in a neighborhood of f the set $K^{-1}(C)$ should be a submanifold of codimension 1; each “tangent vector” W at f with $K_*(W) = 0$ is a tangent vector to the submanifold $K^{-1}(C)$ and should therefore come from a “curve” α in $K^{-1}(C)$. The classical argument runs as follows.

13. LEMMA. If $K(f) = C$, where the C^2 function f is not a critical point of K , and $K_*(W) = K_{f*}(W) = 0$, then $W = \partial\alpha/\partial u(0, t)$ for some variation α with the property that each $\bar{\alpha}(u)$ is in $K^{-1}(C)$.

PROOF. Since f is not a critical point, there is W_1 with $K_*(W_1) \neq 0$. Let $L: \mathbb{R}^2 \rightarrow \mathbb{R}$ be

$$L(r, s) = K(f + rW + sW_1).$$

If we define

$$\beta(u, t) = f(t) + uW_1(t),$$

then β is a variation of f with $\partial\beta/\partial u(0, t) = W_1(t)$ and $\bar{\beta}(u) = f + uW_1$. So

$$K_*(W_1) = \lim_{u \rightarrow 0} \frac{K(f + uW_1) - K(f)}{u} = \frac{\partial L}{\partial s}(0, 0).$$

Similarly,

$$K_*(W) = \frac{\partial L}{\partial r}(0, 0).$$

Since

$$\begin{cases} L(0, 0) = K(f) = C \\ \frac{\partial L}{\partial s}(0, 0) = K_*(W_1) \neq 0, \end{cases}$$

the implicit function theorem shows that there is a C^2 function $r \mapsto s(r)$, from a neighborhood of 0 in \mathbb{R} to a neighborhood of 0 in \mathbb{R} , such that

$$(1) \quad C = L(r, s(r)) = K(f + rW + s(r)W_1) \quad \text{for small } r.$$

Notice that the first part of the equation gives, upon differentiating with respect to r ,

$$0 = \frac{\partial L}{\partial r}(0, 0) + \frac{\partial L}{\partial s}(0, 0)s'(0) = K_*(W) + K_*(W_1)s'(0) = K_*(W_1)s'(0),$$

and hence

$$s'(0) = 0.$$

Thus, if we define the variation α by

$$\alpha(u, t) = f(t) + uW(t) + s(u)W_1(t),$$

then each $\bar{\alpha}(u) = f + uW + s(u)W_1$ is in $K^{-1}(C)$ by (1), and also

$$\frac{\partial \alpha}{\partial u}(0, t) = W(t) + s'(0)W_1(t) = W(t). \quad \spadesuit$$

14. **THEOREM (EULER'S RULE).** If the maximum or minimum of J on $K^{-1}(C)$ occurs at a C^2 function f which is not a critical point of K , then there is a number λ such that f is a critical point of $J - \lambda K$ (and consequently the Euler equations for $J - \lambda K$ hold for f).

PROOF. Consider the two linear functions $J_*, K_*: \mathcal{V} \rightarrow \mathbb{R}$. If $K_*(W) = 0$, let α be the variation given by Proposition 13, with all $\bar{\alpha}(u)$ in $K^{-1}(C)$. Since the maximum or minimum of J on $K^{-1}(C)$ occurs at f , the function $u \mapsto J(\bar{\alpha}(u))$ has a maximum or minimum at 0, and consequently

$$J_*(W) = \left. \frac{dJ(\bar{\alpha}(u))}{du} \right|_{u=0} = 0.$$

Thus $\ker K_* \subset \ker J_*$. The vector space \mathcal{V} is infinite dimensional, but it still follows (Problem 3-2) that there is a number λ with $J_* = \lambda K_*$, which is equivalent to the assertion that f is a critical point of $J - \lambda K$. ♦

In Problem I.9-19, we showed that the Euler equations actually make sense and hold for a critical function of J which is only known to be C^1 . A similar result holds for Euler's Rule; because this strengthened form of the rule will be so important for us, the details of the proof will be given here.

Let f be a C^1 function on $[a, b]$, and let W be a C^1 function with $W(a) = W(b) = 0$. Since we no longer have equation (**) on pg. I.319, we can no longer define $J_{f*}(W)$ quite as before. Instead we define

$$J_*(W) = J_{f*}(W) = \left. \frac{dJ(\bar{\alpha}(u))}{du} \right|_{u=0},$$

where α is the particular variation

$$\alpha(u, t) = f(t) + uW(t).$$

The formula in Problem I.9-19 shows that

$$J_*(W) = \int_a^b W'(t) \left[\frac{\partial F}{\partial y'}(t, f(t), f'(t)) - \int_a^t \frac{\partial F}{\partial x}(t, f(t), f'(t)) dt \right] dt.$$

We define $K_*(W)$ similarly. It is clear that J_* and K_* are linear. Notice that if f is a critical point of K , in the sense that $dK(\bar{\alpha}(u))/du|_{u=0} = 0$ for all variations α keeping endpoints fixed, then surely $K_*(W) = 0$ for all W . Conversely, suppose that $K_*(W) = 0$ for all W . Then Du Bois Reymond's Lemma (see Problem I.9-19) shows that

$$\frac{\partial G}{\partial y'}(t, f(t), f'(t)) - \int_a^t \frac{\partial G}{\partial x}(t, f(t), f'(t)) dt = c,$$

for some constant c . So for any variation α keeping endpoints fixed we have (pg. I.355)

$$\begin{aligned} \left. \frac{dK(\bar{\alpha}(u))}{du} \right|_{u=0} &= c \int_a^b \frac{\partial^2 \alpha}{\partial u \partial t}(0, t) dt = c \left[\frac{\partial \alpha}{\partial u}(0, b) - \frac{\partial \alpha}{\partial u}(0, a) \right] \\ &= 0 - 0. \end{aligned}$$

Thus f is a critical point for K if and only if $K_{f*}(W) = 0$ for all W .

13'. LEMMA. If $K(f) = C$, where the C^1 function f is not a critical point of K , and $K_*(W) = 0$, then $W = \partial \alpha / \partial u(0, t)$ for some variation α [not of the special sort considered above] with the property that each $\bar{\alpha}(u)$ is in $K^{-1}(C)$.

PROOF. The proof of Proposition 13 goes through unchanged; all variations constructed in the proof are of the special sort considered above, except for the final variation α . ♦

14'. THEOREM (EULER'S RULE FOR C^1 FUNCTIONS). If the maximum or minimum of J on $K^{-1}(C)$ occurs at a C^1 function f which is not a critical point of K , then there is a number λ such that f is a critical point of $J - \lambda K$ (and consequently the Euler equations for $J - \lambda K$ make sense and hold for f , by Problem I.9-19).

PROOF. Let \mathcal{W} be the vector space of all C^1 functions W on $[a, b]$ with $W(a) = W(b) = 0$, and consider the two linear functions $J_*, K_*: \mathcal{W} \rightarrow \mathbb{R}$. If $K_*(W) = 0$, let α be the variation given by Proposition 13'. Then the function $u \mapsto J(\bar{\alpha}(u))$ has a maximum or minimum at 0, and consequently

$$\begin{aligned} 0 &= \left. \frac{dJ(\bar{\alpha}(u))}{du} \right|_{u=0} \\ &= \int_a^b W'(t) \left[\frac{\partial F}{\partial y}(t, f(t), f'(t)) - \int_a^t \frac{\partial F}{\partial x}(t, f(t), f'(t)) dt \right] dt \\ &\quad \text{by Problem I.9-19} \\ &= J_*(W). \end{aligned}$$

Thus $\ker K_* \subset \ker J_*$. So there is a number λ with $J_* = \lambda K_*$ on \mathcal{W} . This means that

$$\begin{aligned} &\int_a^b W'(t) \left[\frac{\partial F}{\partial y}(t, f(t), f'(t)) - \int_a^t \frac{\partial F}{\partial x}(t, f(t), f'(t)) dt \right] dt \\ &= \int_a^b W'(t) \lambda \left[\frac{\partial G}{\partial y}(t, f(t), f'(t)) - \int_a^t \frac{\partial G}{\partial x}(t, f(t), f'(t)) dt \right] dt, \end{aligned}$$

for all $W \in \mathcal{W}$. Du Bois Reymond's Lemma then implies, as in the argument preceding Lemma 13', that f is a critical point of $J - \lambda K$. ♦

Notice that, as in the simpler case of functions on \mathbb{R}^n , the dual problem has exactly the same critical points as the original.

Given a certain amount of trust, that similar results hold for functions $f: [a, b] \rightarrow \mathbb{R}^m$, we can finally tackle the classical isoperimetric problem. Consider an imbedding $f: S^1 \rightarrow \mathbb{R}^2$, and let $\alpha: (-\varepsilon, \varepsilon) \times S^1 \rightarrow \mathbb{R}^2$ be a variation of f through imbeddings. For the length $L(\bar{\alpha}(u))$ of $\bar{\alpha}(u)(S^1)$ we have, by formula (I) on page 293,

$$\begin{aligned} \left. \frac{dL(\bar{\alpha}(u))}{du} \right|_{u=0} &= - \int_{S^1} \langle W, \eta \rangle ds \\ &= - \int_{S^1} \langle W, \mathbf{n} \rangle \cdot \kappa ds, \end{aligned}$$

where \mathbf{n} is the principal normal of f and κ is the curvature of f . For the area $A(\bar{\alpha}(u))$ bounded by $\bar{\alpha}(u)(S^1)$ we easily derive, from formula (II) on page 293,

$$\left. \frac{dA(\bar{\alpha}(u))}{du} \right|_{u=0} = \int_{S^1} \langle W, \mathbf{n} \rangle ds.$$

We want to find the imbedding $f: S^1 \rightarrow \mathbb{R}^2$ which maximizes A for fixed L . Since $f(S^1)$ cannot lie on a straight line, f is not a critical point for L . Therefore Euler's Rule shows that there is some λ with

$$\begin{aligned} 0 &= \int_{S^1} \langle W, \mathbf{n} \rangle ds + \lambda \int_{S^1} \langle W, \mathbf{n} \rangle \cdot \kappa ds \\ &= \int_{S^1} \langle W, \mathbf{n} \rangle [1 + \lambda \kappa] ds, \end{aligned}$$

for all variations W . It clearly follows that we must have $1 + \lambda \kappa = 0$, so κ must be a constant, $-1/\lambda$, and f must be an imbedding as a circle.

[It is perhaps worth pointing out that for this problem one can give an elementary proof that if $L_*(W) = 0$ for some W , then there is a variation $\alpha: (-\varepsilon, \varepsilon) \times S^1 \rightarrow \mathbb{R}^2$ of f with $\partial\alpha/\partial u(0, t) = W$, for which each $\bar{\alpha}(u)(S^1)$ has length $L(0)$. In fact, if β is any variation with $\partial\beta/\partial u(0, t) = W(t)$, then we can set

$$\alpha(u, t) = \frac{L(0)}{L(u)} \cdot \beta(u, t) \in \mathbb{R}^2. \quad L(u) = \text{length of } \bar{\beta}(u)(S^1).$$

We have

$$\begin{aligned}\frac{\partial \alpha}{\partial u}(0, t) &= 1 \cdot \frac{\partial \beta}{\partial u}(0, t) - \frac{L'(0)}{L(0)^2} \cdot \beta(0, t) \\ &= \frac{\partial \beta}{\partial u}(0, t), \quad \text{since } L'(0) = L_*(W) = 0;\end{aligned}$$

and

$$\begin{aligned}\text{length of } \bar{\alpha}(u)(S^1) &= \frac{L(0)}{L(u)} \cdot \text{length of } \bar{\beta}(u)(S^1) \\ &= \frac{L(0)}{L(u)} \cdot L(u) = L(0),\end{aligned}$$

as desired.]

We can also apply Euler's Rule to the dual problem of finding the imbedding $f: S^1 \rightarrow \mathbb{R}^2$ which minimizes L for fixed A . Since no f can be a critical point for A , we find once again that $f(S^1)$ must be a circle. Finally, consider the problem of Dido, to join two fixed points P and Q by a curve c of fixed length $L > d(P, Q)$ so that the area enclosed by c and the line segment \overline{PQ} is a maximum. We consider an imbedding $f: [a, b] \rightarrow \mathbb{R}^2$ with $f(a) = P$ and $f(b) = Q$, and let $\alpha: (-\varepsilon, \varepsilon) \times [a, b] \rightarrow \mathbb{R}^2$ be a variation of f through imbeddings. For the length $L(\bar{\alpha}(u))$ of $\bar{\alpha}(u)([a, b])$ we have, by formula (I) on page 293,

$$\left. \frac{dL(\bar{\alpha}(u))}{du} \right|_{u=0} = - \int_a^b \langle W, \mathbf{n} \rangle \cdot \kappa \, ds,$$

while for the area $A(\bar{\alpha}(u))$ bounded by $\bar{\alpha}(u)([a, b])$ and \overline{PQ} , formula (II) on page 293 reduces to

$$\left. \frac{dA(\bar{\alpha}(u))}{du} \right|_{u=0} = \int_a^b \langle W, \mathbf{n} \rangle \, ds.$$

Euler's Rule shows, once again, that f must have constant curvature, so that $f([a, b])$ must be an arc of a circle. We find the same result for the dual problem.

There are, unfortunately, two difficulties with our solution of the isoperimetric problem. We have been working with C^1 curves, and we could have obtained similar results for piecewise C^1 curves with a little more effort. But the obvious class of curves to consider for the isoperimetric problem is the class of rectifiable curves, the curves with finite length (defined as the least upper bound of the lengths of inscribed polygonal curves). Moreover, we have merely found that the circle is the solution of the isoperimetric problem *if a solution exists*; we have not proved that the circle actually is a solution.

Although this will lead us astray from the righteous path of differential geometry, at this point I cannot resist the impulse to mention one of the extremely clever solutions of the isoperimetric problem, involving no assumptions about differentiability, which was given by the great geometer Steiner. Note first that we might as well restrict our attention to convex curves, because the convex hull C^* of a nonconvex curve C has smaller length and encloses a larger area—a suitable region C^{**} similar to C^* will then have the same length as C , and yet still larger area.

Let us therefore consider a convex curve C which is not a circle. We will show that it cannot be a solution to the isoperimetric problem. Choose two points A and B on C which divide C into two curves C_1 and C_2 of equal length, and let R_i be the region bounded by C_i and the line segment AB . We can assume that $\text{area } R_1 \geq \text{area } R_2$; we claim that we actually have $\text{area } R_1 = \text{area } R_2$. To prove

this, we reflect region R_1 in the line AB , obtaining a region R_1' on the opposite side. Then $R_1 \cup R_1'$ has area \geq the area of $R_1 \cup R_2$, while its circumference is the same. If C is a solution to the isoperimetric problem, then we must actually have $\text{area } R_1 \cup R_1' = \text{area } R_1 \cup R_2$, so we have $\text{area } R_1 = \text{area } R_1' = \text{area } R_2$.

Now since C is not a circle, we can choose A and B so that neither C_1 nor C_2 is a semi-circle. Since $\text{area } R_1 = \text{area } R_2$, the region $R_1 \cup R_1'$ with boundary $C_1 \cup C_1'$ will be another solution to the isoperimetric problem, and it will also not be a circle. In other words, we can assume that C is symmetric with respect to AB .

Now there is a point P on C_1 such that $\angle APB$ is *not* a right angle; let Q be the symmetric point on C_2 . The region inside C is made up of the quadrilateral $APBQ$ together with 4 regions T_1, \dots, T_4 as shown in the left half of the figure on the top of the next page. In the right half of this figure we have drawn

a quadrilateral $\bar{A}\bar{P}\bar{B}\bar{Q}$ with $AP = AQ = \bar{A}\bar{P} = \bar{A}\bar{Q}$ and $BP = BQ = \bar{B}\bar{P} = \bar{B}\bar{Q}$, but with $\angle\bar{A}\bar{P}\bar{B}$ and $\angle\bar{A}\bar{Q}\bar{B}$ both right angles. Then on $\bar{A}\bar{P}$ we have drawn a region \bar{T}_1 congruent to the region T_1 in part (a), and regions $\bar{T}_2, \dots, \bar{T}_4$ have been drawn similarly. The new figure clearly has the same circumference as the original curve C . On the other hand, it has *larger* area, since the quadrilateral $\bar{A}\bar{P}\bar{B}\bar{Q}$ clearly has larger area than $APBQ$. Thus C could not be a solution to the isoperimetric problem. This completes the proof that a circle is the only curve which can be a solution to the isoperimetric problem.

This ingenious proof, although it assumes absolutely nothing about the differentiability of C , still has a defect, which, to be sure, Steiner would never have worried about. This proof, like our previous one, shows only that the circle is the solution of the isoperimetric problem, *if a solution exists*. In Blaschke {1}, {2}, one can find many rigorous solutions of the isoperimetric problem which avoid this pitfall by showing that for a closed curve of length L , enclosing a region of area A , we always have $L^2 - 4\pi A \geq 0$, with equality only when the curve is a circle. These proofs exhibit various degrees of ingenuity and elegance, but there is also a straightforward, if somewhat lengthy, direct proof of existence, which will be useful for us to examine.

Let (X, d) be a bounded metric space, and let $\mathcal{C}(X)$ be the set of all non-empty closed subsets of X . The distance $d(x, C)$ from a point $x \in X$ to a closed set $C \in \mathcal{C}(X)$ is defined as

$$d(x, C) = \min_{y \in C} d(x, y),$$

and we define the ε -neighborhood $V_\varepsilon(C)$ of C as

$$V_\varepsilon(C) = \{x : d(x, C) < \varepsilon\}.$$

Given $C_1, C_2 \in \mathcal{C}(X)$, we then define

$$\rho(C_1, C_2) = \inf \{\varepsilon > 0 : C_1 \subset V_\varepsilon(C_2) \text{ and } C_2 \subset V_\varepsilon(C_1)\}.$$

It is easy to check that ρ is a metric, the **Hausdorff metric**, on $\mathcal{C}(X)$. When X is compact, the corresponding topology on $\mathcal{C}(X)$ depends only on the topology of X , not on the given metric d , since any neighborhood of $C \in \mathcal{C}(X)$ contains an ε -neighborhood.

15. PROPOSITION. If (X, d) is compact, then so is $(\mathcal{C}(X), \rho)$.

PROOF. Given $\varepsilon > 0$, choose a finite number of sets A_1, \dots, A_n of diameter $< \varepsilon$ which cover X . For each finite set $F \subset \{1, \dots, n\}$ let

$$\mathcal{A}_F = \{C \in \mathcal{C}(X) : C \cap A_j \neq \emptyset \iff j \in F\}.$$

Then the sets \mathcal{A}_F cover $\mathcal{C}(X)$ and have diameter $\leq 2\varepsilon$. This shows that $(\mathcal{C}(X), \rho)$ is totally bounded.

Now let C_1, C_2, \dots be a Cauchy sequence in $(\mathcal{C}(X), \rho)$. Let C be the set of all $x \in X$ such that every neighborhood of x contains points from infinitely many C_n . The set C is non-empty, for if $x_n \in C_n$ and x is an accumulation point of the sequence $\{x_n\}$, then $x \in C$. It is also clear that C is closed. We claim that $C = \lim C_n$. Given $\varepsilon > 0$, we first show that the C_n are eventually in the open ε -neighborhood $V_\varepsilon(C)$ of C . For suppose that an infinite sequence C_{i_1}, C_{i_2}, \dots intersected the compact set $X - V_\varepsilon(C)$. Then we could choose $x_{i_n} \in C_{i_n} \cap [X - V_\varepsilon(C)]$; some point $x \in X - V_\varepsilon(C)$ would be an accumulation point of the sequence $\{x_{i_n}\}$, hence $x \in C$, a contradiction. We also claim that C is in $V_\varepsilon(C_n)$ for sufficiently large n . In fact, since C_n is a Cauchy sequence, there is some N such that $C_m \subset V_{\varepsilon/2}(C_n)$ for all $m, n > N$; this implies that $V_{\varepsilon/2}(C_m) \subset V_\varepsilon(C_n)$ for all $m, n > N$. So if $n > N$ and C is not contained in $V_\varepsilon(C_n)$, then also C contains a point which is not in $V_{\varepsilon/2}(C_m)$ for all $m > N$, which is clearly impossible. ♦

We will apply this result to the case where X is a closed disc in \mathbb{R}^2 . The set $\text{Con}(X) \subset \mathcal{C}(X)$ consisting of all non-empty closed *convex* subsets of X is easily seen to be a closed, and hence compact, subset of $\mathcal{C}(X)$. If $A: \mathcal{C}(X) \rightarrow \mathbb{R}$ is the function $A(C) = \text{area of } C$ ($=$ Lebesgue measure of A , say), then A is clearly continuous. Define $L: \text{Con}(X) \rightarrow \mathbb{R}$ by $L(C) = \text{length of boundary } C$.

16. PROPOSITION. The function $L: \text{Con}(X) \rightarrow \mathbb{R}$ is continuous.

PROOF. If $\rho(C_1, C_2) < \varepsilon$, then $C_1 \subset (1 + \varepsilon) \cdot C_2$ and $C_2 \subset (1 + \varepsilon) \cdot C_1$, so the result follows from

17. LEMMA. If γ_1 and γ_2 are convex curves with γ_1 contained inside γ_2 , then $\text{length } \gamma_1 \leq \text{length } \gamma_2$.

PROOF. The following picture shows that if P is a polygonal arc inscribed

in γ_1 , then P is shorter than some polygonal arc P' inscribed in γ_2 . ♦

It is now an easy matter to prove the existence of a (convex) curve, with fixed length L_0 , of maximum area: We can clearly restrict our attention to convex sets contained within a closed disc X of radius L_0 ; then the set $L^{-1}(L_0) \subset \text{Con}(X)$ is a closed subset of the compact space $\text{Con}(X)$, so the continuous function A takes on its maximum somewhere on the set. This proof of existence, together with Steiner's argument, rigorously solves the isoperimetric problem. The dual problem can be handled similarly. Its solution is also contained in our solution of the original problem, for we now know that the relation $L^2 - 4\pi A \geq 0$ always holds, with equality only for circles, and this proves that the circle is also the solution of the dual problem. It is also easy to derive this fact from the solution of the original problem by using the similarities of the plane. Finally we mention that the problem of Dido can be settled by similar methods; for instance, we can consider the space of all closed convex sets which have a given line segment PQ as part of their boundary:

I would now like to discuss briefly a line of argument which could be used if Steiner's argument were not available, and we had to rely solely on Euler's Rule. Clearly the only problem is to show that the solution of the isoperimetric problem (whose existence we can prove) must be a C^1 curve. The first step would be to show that the solution curve has a tangent line everywhere. Now it is well-known (Problem 2) that a convex function always has left- and right-hand

derivatives, so we just have to show that our convex curve has no corners. If our curve actually contained two straight line segments AB and AC meeting at an angle at A , then it would be easy to show that it is not a solution to the

isoperimetric problem. For the two segments could be replaced by an arc of a circle with equal length, but enclosing larger area, since such an arc is a solution to the problem of Dido. One doesn't really need the whole solution to the problem of Dido to reach this conclusion, however, for a simple calculation will show that the appropriate arc together with line BC encloses more area than triangle ABC . (If we had worked out the calculus of variations argument for piecewise C^1 curves we would have another way of seeing that the two segments can be replaced by some nearby curve of the same length, but enclosing larger area.) In the general case, the same idea can be made to work by an approximation argument.

Now it is also easy to see (Problem 2) that if a convex function is everywhere differentiable, then its derivative is *automatically* continuous. This shows that the solution to the isoperimetric problem must be a C^1 curve; Euler's Rule then leads to the conclusion that it must be a circle.

As differential geometers, we naturally think of generalizing the isoperimetric problem to an arbitrary surface M . Given a variation $\alpha: (-\varepsilon, \varepsilon) \times S^1 \rightarrow M$ of a map $f: S^1 \rightarrow M$ we now have

$$\begin{aligned} \left. \frac{dA(\bar{\alpha}(u))}{du} \right|_{u=0} &= \int_{S^1} \langle W, \mathbf{u} \rangle ds, \\ \left. \frac{dL(\bar{\alpha}(u))}{du} \right|_{u=0} &= - \int_{S^1} \langle W, \eta \rangle ds \\ &= - \int_{S^1} \langle W, \mathbf{u} \rangle \kappa_g ds, \end{aligned}$$

where \mathbf{u} is the second member of the Darboux frame for f , and κ_g is the geodesic curvature of f . These formulas, together with a few ruthlessly suppressed details which are necessary to transfer Euler's Rule from \mathbb{R}^m to manifolds, show that if f maximizes A for fixed L , then there is a constant λ such that

$$\begin{aligned} 0 &= \int_{S^1} \langle W, \mathbf{u} \rangle ds + \lambda \int_{S^1} \langle W, \mathbf{u} \rangle \kappa_g ds \\ &= \int_{S^1} \langle W, \mathbf{u} \rangle [1 + \lambda \kappa_g] ds \end{aligned}$$

for all variations W . This implies that f has *constant geodesic curvature*. The geodesic curvature was first invented by Minding, in 1830, when he obtained this solution (for the problem of Dido, rather than the isoperimetric problem). Minding dealt with surfaces in \mathbb{R}^3 , and defined κ_g extrinsically, but he then showed that it was a bending invariant; its present name was given it by Bonnet, in 1848.

A rigorous discussion of the isoperimetric problem on an arbitrary surface M is considerably more complicated than for the plane, if for no other reason than because the problem itself is more involved. First of all, Euler's Rule is not always applicable, because there might be closed curves which are geodesics, and consequently critical points for L . For example, on the surface M shown below, the equator C of the smaller spherical part is *not* a critical point for

area among all curves with length equal to $L(C)$. We can obtain a variation α of C by moving C up distance u along geodesics perpendicular to C , and then adding on a bulge to bring the length up to $L(C)$. Then $A(u) - A(0)$ is greater than the area of M enclosed between two parallel planes at distance $\sin u$ (see the third picture above), so

$$A(u) - A(0) > \sin u$$

and consequently $A'(0) \neq 0$.

The figure below shows a curve C' on M , with $L(C') = L(C)$, which is a critical point for A among curves with this length. If we accept the fact that

a circle is a solution to the isoperimetric problem on the sphere, then C' must be a solution to the isoperimetric problem on M . Of course, we really have to decide which of the two regions of M bounded by C' should be maximized; if we take the top region, then C' actually minimizes. The necessity of making this decision correctly is further illustrated by the fact that there is another curve C'' higher up with length L that is also a critical point for A among curves of this length. In fact, if we make the wrong decision we might be led to say that there are curves of length L bounding regions with area arbitrarily close to that of M . This becomes quite critical if there is a closed curve of length L which

divides M into two pieces with the same area, as may happen for example on a sphere.

I also suspect that in some cases the solution of the isoperimetric problem will have to be a curve which intersects itself, as in the following picture; notice that

we want the curve to go around as much as possible of the part of the surface with large curvature.

Finally, we point out that on most surfaces there will be just a few solutions of the isoperimetric problem, and that they may be completely different curves. In this respect the problem of Dido is more natural on a general surface; given a geodesic segment γ from P to Q , we would expect that among all curves c from P to Q with given length $L > d(P, Q)$ there is just one on each side of γ which maximizes the area enclosed by γ and c .

I think that a reasonable approach to the isoperimetric problem on a compact surface M is to consider only lengths L so small that a closed curve of length L must be contained in a geodesically convex set. It is then clear that our solution must be the boundary of a geodesically convex set, and there is no problem deciding which region it bounds. All our previous considerations can be suitably modified to show that a solution of the isoperimetric problem exists and is C^1 , so that it must have constant geodesic curvature. This proves, in particular, that there are *closed* curves of constant geodesic curvature; proving this result directly seems almost hopeless. By the way, it is a classical theorem that if *every* curve of constant geodesic curvature is closed, then M must have constant curvature (Blaschke {1}).

In this connection, an interesting experiment can be performed with a soap film on a wire loop. If a small loop of thread held between two thin sticks is dipped into the soap solution, it can then be thrust into the soap film without breaking it. If the part of the soap film inside the thread is then broken, and

the sticks are removed, the thread should take a form which is a solution to the isoperimetric problem on the soap film. When one tries this experiment it turns out that, unless the wire loop is very flat, the string always rushes off toward the wire loop, no matter where it is placed. I take this to mean that there are no curves of constant geodesic curvature on a non-flat minimal surface,

but I haven't the slightest idea how one would prove it. [Actually, as Osserman pointed out to me, the experiment involves a rather more complicated problem, since the shape of the surface *changes* as the thread moves.]

For our next application of Euler's Rule we will work only in \mathbb{R}^3 , and consider the 3-dimensional isoperimetric problem, to find the surface of fixed area A which encloses the greatest volume. Consider an imbedding $f: S^2 \rightarrow \mathbb{R}^3$, and let $\alpha: (-\varepsilon, \varepsilon) \times S^2 \rightarrow \mathbb{R}^3$ be a variation of f through imbeddings. For the area $A(\bar{\alpha}(u))$ of $\bar{\alpha}(u)(S^2)$ we have, by formula (I) on page 294,

$$\begin{aligned} \left. \frac{dA(\bar{\alpha}(u))}{du} \right|_{u=0} &= - \int_{S^2} \langle W, \eta \rangle dA \\ &= - \int_{S^2} 2H \langle W, \nu \rangle dA, \end{aligned}$$

where ν is the normal of $f(S^2)$ and H is the mean curvature. For the volume $V(\bar{\alpha}(u))$ enclosed by $\bar{\alpha}(u)(S^2)$ we have, by formula (II) on page 294,

$$\left. \frac{dV(\bar{\alpha}(u))}{du} \right|_{u=0} = \int_{S^2} \langle W, \nu \rangle dA.$$

We want to find the imbedding $f: S^2 \rightarrow \mathbb{R}^3$ which maximizes V for fixed A . Since the compact surface $f(S^2)$ cannot have $H = 0$ everywhere (Corollary 7-31), f is not a critical point for A . Therefore Euler's Rule shows that there is some λ with

$$0 = \int_{S^2} \langle W, \nu \rangle dA + \lambda \int_{S^2} 2H \langle W, \nu \rangle dA = \int_{S^2} \langle W, \nu \rangle [1 + 2\lambda H] dA$$

for all variations W . It clearly follows that $f(S^2)$ must have *constant mean curvature*.

At this point we encounter new difficulties, for we first have to find all the surfaces of constant mean curvature. This particular problem is interesting of itself, quite apart from any connection with the isoperimetric problem. For one thing, such surfaces are the possible shape for soap bubbles—the increased air pressure within the bubble naturally makes it take a form which maximizes the enclosed volume. We already know (Theorem 5-3) that a *convex* surface with constant mean curvature must be a standard sphere. H. Hopf [1] proved that an immersed surface homeomorphic to S^2 with constant mean curvature must be a standard sphere. The proof of this is deferred to Addendum 2, since it uses the existence of isothermal parameters, which is proved in Addendum 1. Alexandrov [1] proved that any *imbedded* compact hypersurface of \mathbb{R}^{n+1} with

constant mean curvature must be a standard sphere; this proof is presented in Addendum 3. Alexandrov's theorem holds just as well for hypersurfaces in the hyperbolic space H^{n+1} or in an open hemisphere of S^{n+1} . It definitely fails even for surfaces with $H = 0$ in the sphere S^3 , as we mentioned on page 294.

It was long unknown (Hopf's Problem) whether every *immersed* compact hypersurface with constant mean curvature is a standard sphere, and although this was widely suspected to be the case, the previous edition of this volume mischievously suggested that "some one may some day blow a soap bubble in the shape of an immersed torus". As far as I know, no one has yet done that, but in 1986 Wente [1] proved that there are indeed immersed tori with constant mean curvature. His detailed proof combined methods from complex analysis and recent results on partial differential equations. Noting symmetries in computer-generated pictures of such immersed tori, Abresch [1] searched for examples with one family of planar curvature lines, and was able to reduce the problem to an ODE that can be solved explicitly in terms of elliptic functions. Finally, Kapouleas [1], [2] proved that other surfaces could also be immersed with constant mean curvature.

At first sight the isoperimetric problem seems easier, since it seems that a solution ought to be convex. Proving this directly seems almost hopeless, however, for the boundary of the convex hull C^* of a set C in \mathbb{R}^3 may well have *larger* surface area than the boundary of C . Of course, the volume of C^* is also

larger than that of C —the big question is whether it is larger by enough. In Blaschke {2} there is a proof that the sphere is the solution to the isoperimetric problem provided that we restrict our attention to convex sets. In the general case there is such an overwhelming multitude of problems, not least of which is the difficulty of *defining* surface area, that we will say no more about the problem, merely referring the interested reader to the bibliography.

To conclude this rather disconnected series of remarks, we shall very briefly discuss a problem which requires for its solution even more elaborate machinery than any yet mentioned, but which is of much greater interest to differential

geometry. In his investigations of the “three body problem”, Poincaré was led to consider simple closed geodesics on a compact convex surface $M \subset \mathbb{R}^3$. Poincaré gave a rather long proof that at least one simple closed geodesic exists on M , and then outlined a much more direct argument for the same conclusion. Although many (probably hopelessly difficult) subsidiary results would be required to make this argument into a complete proof, it is nevertheless an interesting application of Euler’s rule for isoperimetric problems. We notice first that if c is a simple closed geodesic on M , then Theorem 6-5 implies that $v \circ c$ divides S^2 into two regions each of area 2π . To establish the existence of such a geodesic, we will consider the set of all simple closed curves γ on M such that $v \circ \gamma$ divides S^2 into two regions of equal area, and then among these choose one, $c: S^1 \rightarrow M$, of shortest length. We claim that c must be a geodesic. To prove this we consider a variation $\alpha: (-\varepsilon, \varepsilon) \times S^1 \rightarrow M$ of c . For the length $L(\bar{\alpha}(u))$ of $\bar{\alpha}(u)(S^1)$ we have, by the formula on page 307,

$$(1) \quad \left. \frac{dL(\bar{\alpha}(u))}{du} \right|_{u=0} = - \int_{S^1} \langle W, \mathbf{u} \rangle \cdot \kappa_g ds.$$

Now extend f to a map $f: D \rightarrow M$, of the unit disc into M , so that $f(D)$ is one of the regions bounded by $f(S^1)$; extend α to a map $\alpha: (-\varepsilon, \varepsilon) \times D \rightarrow M$ similarly. Let $A(\bar{\alpha}(u))$ be the area of the image $v(\bar{\alpha}(u)(D)) \subset S^2$. Then

$$A(\bar{\alpha}(u)) = \int_{\bar{\alpha}(u)(D)} K dA,$$

where dA is the volume element of M and K is the Gaussian curvature of M . It certainly seems reasonable that we should have

$$(2) \quad \left. \frac{dA(\bar{\alpha}(u))}{du} \right|_{u=0} = \int_{S^1} (K \circ f) \langle W, \mathbf{u} \rangle ds,$$

for $A(\bar{\alpha}(h)) - A(\bar{\alpha}(0))$ is the integral of $K dA$ over a small band around $f(S^1)$ whose width is given approximately by the function $\langle W, \mathbf{u} \rangle$. To prove this rigorously, we write $A(\bar{\alpha}(u))$ as

$$A(\bar{\alpha}(u)) = \int_D [K \circ \bar{\alpha}(u)] \cdot \Gamma(u), \quad \Gamma(u) = \bar{\alpha}(u)^* dA.$$

Then

$$\left. \frac{dA(\bar{\alpha}(u))}{du} \right|_{u=0} = \left. \frac{d}{du} \right|_{u=0} \int_D [K \circ \bar{\alpha}(u)] \cdot \Gamma(u)$$

$$\begin{aligned}
 &= \int_D \left[\frac{d}{du} \Big|_{u=0} K \circ \bar{\alpha}(u) \right] \cdot \Gamma(0) + \int_D (K \circ f) \cdot \dot{\Gamma}(0) \\
 &\quad \text{by Leibnitz's Rule} \\
 &= \int_D \left[\frac{d}{du} \Big|_{u=0} K \circ \bar{\alpha}(u) \right] \cdot \Gamma(0) - \int_D (K \circ f) \langle W, \mathbf{u} \rangle \Gamma(0) \\
 &\quad + \int_{S^1} (K \circ f) (W \lrcorner \Gamma(0)) \quad \text{by Theorem 11} \\
 &= \int_{S^1} (K \circ f) \cdot (W \lrcorner \Gamma(0)) \\
 &= \int_{S^1} (K \circ f) \cdot \langle W, \mathbf{u} \rangle ds.
 \end{aligned}$$

Now if our curve c is a solution to the isoperimetric problem of minimizing L for fixed $A = 2\pi$, then Euler's rule says that there is a constant λ such that

$$0 = \int_{S^1} \langle W, \mathbf{u} \rangle [\lambda(K \circ f) - \kappa_g] ds$$

for all variations W . This implies that $\kappa_g = \lambda(K \circ f)$. On the other hand, applying Theorem 6-5 to $f(D) \subset M$, we obtain

$$- \int_{S^1} \kappa_g ds + 2\pi = \int_{f(D)} K dA = 2\pi,$$

and thus

$$0 = \int_{S^1} \kappa_g ds = \lambda \int_{S^1} (K \circ f) ds.$$

So if M has $K > 0$ everywhere, then we must have $\lambda = 0$, and thus $\kappa_g = 0$; consequently, c is a geodesic.

In Blaschke {1; pp. 211–212} there is a further argument, due to Herglotz, to show that M actually contains at least 3 closed geodesics. Nowadays, all such results are proved by quite different, rigorous methods, of far greater generality—see Klingenberg {1}.

ADDENDUM 1

ISOTHERMAL COORDINATES

As we mentioned in Volume II, the existence of isothermal coordinates on any surface was first proved by Gauss, who resorted to a trick that works only in the analytic case. Although we will treat the more general case also, Gauss' proof will be given first, as it is interesting in its own right. First we need to review some facts about differential equations. The equation

$$y'(x) = f(x, y(x))$$

is written classically as

$$\frac{dy}{dx} = f(x, y),$$

or even as

$$dy - f(x, y) dx = 0.$$

Most elementary differential equations courses indicate that one method of solving this equation is to find an “integrating factor” for it, that is, a nowhere zero function λ such that $\lambda(dy - f dx)$ is exact, say

$$\lambda(dy - f dx) = dg.$$

Then the solutions of the original equation are the same as the solutions of $dg = 0$, i.e., the curves $g = \text{constant}$. For example, to solve the equation

$$\begin{aligned} 0 &= (x^2 y + x) dy + (x y^2 - y) dx \\ &= x dy - y dx + xy(x dy + y dx), \end{aligned}$$

we multiply by $1/xy$, to obtain

$$0 = \frac{dy}{y} - \frac{dx}{x} + d(xy),$$

with the solution

$$\log y(x) - \log x + x \cdot y(x) = \text{constant}.$$

As a more interesting example, we consider the general first order linear equation

$$\frac{dy}{dx} + \phi(x)y = \psi(x),$$

which we write as

$$[\phi(x)y - \psi(x)] dx + dy = 0.$$

In order for

$$[\lambda(x)\phi(x)y - \lambda(x)\psi(x)] dx + \lambda(x) dy$$

to be exact, we need

$$\frac{\partial}{\partial y} [\lambda(x)\phi(x)y - \lambda(x)\psi(x)] = \frac{d\lambda}{dx}$$

or

$$\begin{aligned} \lambda(x)\phi(x) &= \frac{d\lambda}{dx} \implies \frac{d\lambda}{\lambda} = \phi(x) dx \\ &\implies \log \lambda = \int \phi \\ &\implies \lambda = e^{\int \phi}. \end{aligned}$$

So we write our original equation as

$$e^{\int \phi} \frac{dy}{dx} + e^{\int \phi} \phi(x)y = \psi(x)e^{\int \phi},$$

which gives

$$\begin{aligned} \frac{d}{dx} (e^{\int \phi} y) &= \psi(x)e^{\int \phi}, \\ e^{\int \phi} y &= \int e^{\int \phi} \psi + C, \\ y &= e^{-\int \phi} \left(\int e^{\int \phi} \psi + C \right). \end{aligned}$$

Of course, only in the most fortuitous cases can one find an integrating factor by inspection. What is theoretically more interesting is the observation that for any 1-form

$$(*) \quad \omega = \alpha dx + \beta dy$$

on \mathbb{R}^2 with $\alpha(p_0), \beta(p_0) \neq 0$, an integrating factor exists in a neighborhood of p_0 . To prove this, we consider the differential equation

$$(**) \quad y'(x) = -\frac{\beta}{\alpha}(x, y(x)).$$

Since $-(\beta/\alpha)(p_0) \neq 0$, the integral curves of this differential equation form a foliation in a neighborhood of p_0 and there is a diffeomorphism h from a

neighborhood of p_0 to \mathbb{R}^2 such that the integral curves go into the sets with 2nd coordinate constant. Let

$$g(p) = 2^{\text{nd}} \text{ coordinate of } h(p).$$

Then

$$\begin{aligned} \ker dg(p) &= \text{tangent space at } p \text{ of the solution curve} \\ &\quad \text{of } (**) \text{ going through } p \\ &= \ker \omega(p). \end{aligned}$$

This proves that

$$dg(p) = \lambda(p) \cdot \omega(p)$$

for some $\lambda(p) \neq 0$.

In Problem I.6-9 we showed that the differential equation

$$y'(z) = f(z, y(z)) \quad (' = \text{complex derivative})$$

can always be solved if $f: \mathbb{C} \times \mathbb{C} \rightarrow \mathbb{C}$ is complex analytic. From this we easily conclude, by modifying the preceding argument, that if α and β are complex-valued functions on \mathbb{R}^2 which are the restrictions of complex analytic functions on \mathbb{C}^2 , and $\alpha(p_0), \beta(p_0) \neq 0$, then there is a complex-valued function λ in a neighborhood of p_0 such that

$$\lambda(\alpha dx + \beta dy) = dg$$

for some complex-valued function g ; both λ and g are the restrictions of complex analytic functions on \mathbb{C}^2 . Now we can prove

18. **THEOREM.** Let $\langle \cdot, \cdot \rangle$ be a Riemannian metric on a neighborhood V of $0 \in \mathbb{R}^2$ whose components g_{ij} with respect to the standard coordinate system on \mathbb{R}^2 are C^ω (= real analytic). Then there exists a C^ω isothermal coordinate system for $\langle \cdot, \cdot \rangle$ in a neighborhood of 0 .

PROOF. Let X_1, X_2 be a C^ω orthonormal moving frame in a neighborhood of 0 , with dual 1-forms θ^1, θ^2 . Then

$$\langle \cdot, \cdot \rangle = \theta^1 \otimes \theta^1 + \theta^2 \otimes \theta^2,$$

and consequently the corresponding quadratic function $\| \cdot \|^2$ can be written as

$$\| \cdot \|^2 = \theta^1 \cdot \theta^1 + \theta^2 \cdot \theta^2.$$

Let ϕ be the complex-valued differential form

$$\phi = \theta^1 + i\theta^2, \quad \text{with} \quad \bar{\phi} = \theta^1 - i\theta^2.$$

Then

$$\| \cdot \|^2 = \phi \cdot \bar{\phi}.$$

If we construct X_1, X_2 explicitly by applying the Gram-Schmidt orthonormalization process to $\partial/\partial x^1, \partial/\partial x^2$, then the coefficients of X_1, X_2 will appear as algebraic combinations of the g_{ij} . The same is thus true of θ^1, θ^2 . Since the g_{ij} are C^ω , and hence the restrictions of complex analytic functions on \mathbb{C}^2 , the same is true for θ^1, θ^2 . So by the remark preceding the theorem, there is a complex-valued function λ such that

$$\lambda \phi = dg \implies \bar{\lambda} \bar{\phi} = d\bar{g}$$

for some complex-valued function g . This implies that

$$\lambda \bar{\lambda} \| \cdot \|^2 = \lambda \bar{\lambda} \phi \cdot \bar{\phi} = dg \cdot d\bar{g},$$

so that

$$\| \cdot \|^2 = \frac{1}{\lambda \bar{\lambda}} dg \cdot d\bar{g}.$$

If we write $g = u + iv$ for real-valued u and v , then the Jacobian of $(u, v): \mathbb{R}^2 \rightarrow \mathbb{R}^2$ is not zero, for if it were, then dg would be zero, and hence $\| \cdot \|^2$ would be zero. Now

$$dg \cdot d\bar{g} = du \cdot du + dv \cdot dv,$$

so

$$\| \cdot \|^2 = \frac{1}{\lambda \bar{\lambda}} (du \cdot du + dv \cdot dv).$$

By polarization,

$$\langle \cdot, \cdot \rangle = \frac{1}{\lambda \bar{\lambda}} (du \otimes du + dv \otimes dv).$$

The functions u and v are C^ω since g is the restriction of a complex analytic function on \mathbb{C}^2 . Thus (u, v) is the required C^ω isothermal coordinate system. ♦

The proof of Theorem 18 when the g_{ij} are not C^ω will be **much** more involved. First we introduce some new classes of functions. A function $f: \mathbb{R}^n \rightarrow \mathbb{R}^m$ is said to satisfy a **Hölder condition of order α** ($0 < \alpha < 1$) on $U \subset \mathbb{R}^n$ if there is a constant K such that

$$|f(p) - f(q)| \leq K \cdot |p - q|^\alpha \quad \text{for all } p, q \in U.$$

Such functions are called C^α functions, and a function f is $C^{n+\alpha}$ if all mixed n^{th} order derivatives of f exist and are C^α . We will eventually show that if the g_{ij} in Theorem 18 are C^α , then there is a $C^{1+\alpha}$ isothermal coordinate system in a neighborhood of 0. We will also show that if the g_{ij} are $C^{n+\alpha}$, then this same coordinate system is $C^{n+1+\alpha}$; in particular, if the g_{ij} are C^∞ , so is the coordinate system. There need not be a C^1 isothermal coordinate system when the g_{ij} are merely C^0 (= continuous).

The condition that (u, v) be isothermal is

$$\sum_{i,j} g_{ij} dx^i \otimes dx^j = \langle \ , \ \rangle = \lambda(du \otimes du + dv \otimes dv), \quad \text{some } \lambda > 0.$$

To derive explicit equations for u and v , it is easiest to consider the dual metric $\langle \ , \ \rangle^*$ on $T^*\mathbb{R}^2$, which must satisfy

$$\begin{aligned} \sum_{i,j} g^{ij} \left(\frac{\partial}{\partial x^i} \right)^{**} \otimes \left(\frac{\partial}{\partial x^j} \right)^{**} &= \langle \ , \ \rangle^* \\ &= \frac{1}{\lambda} \left[\left(\frac{\partial}{\partial u} \right)^{**} \otimes \left(\frac{\partial}{\partial u} \right)^{**} + \left(\frac{\partial}{\partial v} \right)^{**} \otimes \left(\frac{\partial}{\partial v} \right)^{**} \right]. \end{aligned}$$

Denoting (x^1, x^2) by (x, y) , setting

$$(g^{ij}) = \begin{pmatrix} a & b \\ b & c \end{pmatrix},$$

and applying our equation to the pairs (du, du) , (dv, dv) , and (du, dv) , we obtain

$$(1) \quad au_x^2 + 2bu_xu_y + cu_y^2 = \frac{1}{\lambda} = av_x^2 + 2bv_xv_y + cv_y^2$$

$$(2) \quad au_xv_x + b(u_xv_y + u_yv_x) + cu_yv_y = 0.$$

Equation (2) can be written

$$u_x(av_x + bv_y) + u_y(bv_x + cv_y) = 0,$$

which implies that there is a function ρ with

$$\begin{aligned} u_x &= \rho(bv_x + cv_y) \\ u_y &= -\rho(av_x + bv_y). \end{aligned}$$

Substituting into (1) we find that

$$\rho^2(ac - b^2) = 1.$$

We thus have the

Beltrami equations:

$$u_x = \frac{bv_x + cv_y}{\sqrt{ac - b^2}}, \quad u_y = -\frac{av_x + bv_y}{\sqrt{ac - b^2}}, \quad \begin{pmatrix} a & b \\ b & c \end{pmatrix} = (g^{ij})$$

as necessary and sufficient conditions that (u, v) be isothermal coordinates for the metric $\langle \cdot, \cdot \rangle = \sum_{i,j=1}^n g_{ij} dx^i \otimes dx^j$.

At this point it becomes extremely convenient to introduce the notation of formal complex derivatives. We will often denote a typical point of $\mathbb{C} = \mathbb{R}^2$ by z , and z will also be used to denote the identity map $z: \mathbb{C} \rightarrow \mathbb{C}$. We have already used $x, y: \mathbb{R}^2 \rightarrow \mathbb{R}$ for the coordinate functions on \mathbb{R}^2 , so the equation $z = x + iy$ is a (true) equation concerning the three complex-valued functions x, y, z on \mathbb{R}^2 . Because of this equation we have

$$dz = dx + i dy, \quad d\bar{z} = dx - i dy.$$

Since any complex-valued differential on \mathbb{R}^2 can be written in terms of dx and dy , it can also be written in terms of dz and $d\bar{z}$. So for any complex-valued function w on \mathbb{R}^2 , there are unique functions $w_z = \partial w / \partial z$ and $w_{\bar{z}} = \partial w / \partial \bar{z}$ with

$$dw = w_z dz + w_{\bar{z}} d\bar{z}.$$

Substituting from the above equations, we have

$$dw = (w_z + w_{\bar{z}}) dx + i(w_z - w_{\bar{z}}) dy,$$

so that

$$\begin{aligned} w_z + w_{\bar{z}} &= \frac{\partial w}{\partial x} = w_x \\ i(w_z - w_{\bar{z}}) &= \frac{\partial w}{\partial y} = w_y, \end{aligned}$$

which gives

$$\boxed{\begin{aligned} w_z &= \frac{1}{2}(w_x - iw_y) \\ w_{\bar{z}} &= \frac{1}{2}(w_x + iw_y) \end{aligned}} \quad \text{or} \quad \boxed{\begin{aligned} w_x &= w_z + w_{\bar{z}} \\ w_y &= \frac{w_{\bar{z}} - w_z}{i}. \end{aligned}}$$

The usual differentiation rules apply to the operators $\partial/\partial z$ and $\partial/\partial \bar{z}$, and we have

$$\begin{aligned} \frac{\partial}{\partial z}(z) &= 1, & \frac{\partial}{\partial \bar{z}}(z) &= 0 \\ \frac{\partial}{\partial \bar{z}}(\bar{z}) &= 1, & \frac{\partial}{\partial z}(\bar{z}) &= 0. \end{aligned}$$

It is also easy to check that we always have

$$w_{z\bar{z}} = w_{\bar{z}z}.$$

Another easily checked result is

$$\bar{w}_{\bar{z}} = \overline{(w_z)}.$$

The chain rule becomes

$$\begin{aligned} (w \circ \zeta)_z &= (w_z \circ \zeta) \cdot \zeta_z + (w_{\bar{z}} \circ \zeta) \cdot \bar{\zeta}_z \\ (w \circ \zeta)_{\bar{z}} &= (w_z \circ \zeta) \cdot \zeta_{\bar{z}} + (w_{\bar{z}} \circ \zeta) \cdot \bar{\zeta}_{\bar{z}}. \end{aligned}$$

[If we agree to write $w_z \circ \zeta = w_\zeta$ and $w_{\bar{z}} \circ \zeta = w_{\bar{\zeta}}$, then we have

$$\begin{aligned} (w \circ \zeta)_z &= w_\zeta \cdot \zeta_z + w_{\bar{\zeta}} \cdot \bar{\zeta}_z \\ (w \circ \zeta)_{\bar{z}} &= w_\zeta \cdot \zeta_{\bar{z}} + w_{\bar{\zeta}} \cdot \bar{\zeta}_{\bar{z}}, \end{aligned}$$

which looks a little nicer.]

Finally, we note that if $w = u + iv$ for real-valued u and v , then the condition

$$0 = w_{\bar{z}} = \frac{1}{2}(u_x + iv_x + i[u_y + iv_y])$$

is equivalent to the Cauchy-Riemann equations

$$u_x = v_y, \quad u_y = -v_x.$$

So $w_{\bar{z}} = 0$ if and only if w is complex analytic on U ; in this case it is also easy to see that

$$w_z = w', \quad \text{the complex derivative.}$$

Now suppose that u, v satisfy the Beltrami equations. If we set

$$w = u + iv,$$

we find that

$$\begin{aligned} 2w_{\bar{z}}\sqrt{ac - b^2} &= (b - ia + i\sqrt{ac - b^2})v_x + (c - ib - \sqrt{ac - b^2})v_y, \\ 2w_z\sqrt{ac - b^2} &= (b + ia + i\sqrt{ac - b^2})v_x + (c + ib + \sqrt{ac - b^2})v_y. \end{aligned}$$

A short calculation shows that the coefficients of v_x and v_y on the right hand sides of these two equations are proportional, and we have

$$\frac{w_{\bar{z}}}{w_z} = \frac{c - a - 2ib}{c + a + 2\sqrt{ac - b^2}}$$

or

$$(*) \quad w_{\bar{z}} = \mu w_z, \quad \mu = \frac{c - a - 2ib}{c + a + 2\sqrt{ac - b^2}}.$$

Conversely, it is easy to see that the Beltrami equations follow from (*). Notice that if the g_{ij} are $C^{n+\alpha}$, then so are a, b, c and hence μ . Moreover, $|\mu| < 1$. Notice also that we always have

$$u_x v_y - u_y v_x = |w_z|^2 - |w_{\bar{z}}|^2.$$

So if w satisfies (*), then

$$u_x v_y - u_y v_x = |w_z|^2(1 - |\mu|^2).$$

Since $|\mu| < 1$, it follows that (u, v) has non-zero Jacobian at any point where $w_z \neq 0$.

The first major step on the road to our final result will be to prove that if μ is C^α and $|\mu(0)| < 1$, then equation (*) has a $C^{1+\alpha}$ solution w in a neighborhood of 0, with $w_z(0) \neq 0$. In outline our proof will go as follows. We will let $D(R)$

denote the open disc of radius $R > 0$. Suppose that f is C^α in $D(R)$. For all $z_0 \in D(R)$, define

$$F(z_0) = -\frac{1}{\pi} \iint_{D(R)} \frac{f(z)}{z - z_0} dx dy \quad (z = x + iy).$$

We will show that

$$(A) \quad F_{\bar{z}}(z_0) = f(z_0).$$

We thus have a way of producing a function F with $F_{\bar{z}} = f$.

Now suppose for the moment that we have a function w satisfying (*). If we define

$$F(z_0) = -\frac{1}{\pi} \iint_{D(R)} \frac{\mu(z)w_z(z)}{z - z_0} dx dy \quad z_0 \in D(R),$$

then (A) gives

$$F_{\bar{z}}(z_0) = \mu(z_0)w_z(z_0) = w_{\bar{z}}(z_0).$$

But this means that $(w - F)_{\bar{z}} = 0$, so $w - F$ is complex analytic. Thus we have

$$w(z_0) = -\frac{1}{\pi} \iint_{D(R)} \frac{\mu(z)w_z(z)}{z - z_0} dx dy + g(z_0),$$

for some complex analytic function g . Conversely, if w satisfies this integral equation for some complex analytic function g , then (A) shows that w satisfies (*), since $g_{\bar{z}} = 0$. We will solve (*) by showing that the equivalent integral equation always has a solution.

In order to get to the proof of (A), we need a succession of simple lemmas.

19. LEMMA (GENERALIZED CAUCHY INTEGRAL THEOREM). Let $D \subset \mathbb{R}^2$ be a compact 2-dimensional manifold-with-boundary, and let $f: D \rightarrow \mathbb{C}$ be C^1 . Then

$$\int_{\partial D} f dz = 2i \iint_D f_{\bar{z}} dx dy.$$

PROOF. If $f = u + iv$ for C^1 functions $u, v: D \rightarrow \mathbb{R}$, then

$$\int_{\partial D} f dz = \int_{\partial D} (u + iv)(dx + i dy) = \int_{\partial D} u dx - v dy + i \int_{\partial D} v dx + u dy,$$

while

$$\begin{aligned} 2i \iint_D f_{\bar{z}} dx dy &= 2i \iint_D \frac{1}{2}(f_x + i f_y) dx dy = \iint_D (-f_y + i f_x) dx dy \\ &= \iint_D (-u_y - v_x) dx dy + i \iint_D (u_x - v_y) dx dy. \end{aligned}$$

The real and imaginary parts of these two expressions are equal by Stokes' Theorem. ♦

Remark: We define the line integral $\int_c f d\bar{z}$ as

$$\int_c f d\bar{z} = \int_c f \cdot (dx - i dy).$$

It is easy to check that this definition is equivalent to the one usually adopted in complex analysis books,

$$\int_c f d\bar{z} = \overline{\left(\int_c \bar{f} dz \right)}.$$

Since

$$\bar{f}_{\bar{z}} = \overline{(f_z)},$$

Lemma 19 gives

$$\begin{aligned} \int_{\partial D} f d\bar{z} &= \overline{\left(\int_{\partial D} \bar{f} dz \right)} = -2i \overline{\left(\iint_D \bar{f}_{\bar{z}} dx dy \right)} \\ &= -2i \iint_D f_z dx dy. \end{aligned}$$

20. LEMMA (GENERALIZED CAUCHY INTEGRAL FORMULA). For f and D as in Lemma 19, and $z_0 \in \text{interior } D$, we have

$$f(z_0) = \frac{1}{2\pi i} \int_{\partial D} \frac{f(z)}{z - z_0} dz - \frac{1}{\pi} \iint_D \frac{f_{\bar{z}}(z)}{z - z_0} dx dy.$$

PROOF. Let $B(\varepsilon) \subset D$ be a disc of radius ε around z_0 . Applying Lemma 19 to the function

$$z \mapsto \frac{f(z)}{z - z_0} \quad \text{on} \quad D - \text{interior } B(\varepsilon),$$

we have

$$2i \iint_{D - \text{int } B(\varepsilon)} \frac{f_{\bar{z}}(z)}{z - z_0} dx dy = \int_{\partial D} \frac{f(z)}{z - z_0} dz + \int_{\partial B(\varepsilon)} \frac{f(z)}{z - z_0} dz.$$

Taking the limit as $\varepsilon \rightarrow 0$, we find that

$$2i \iint_D \frac{f_{\bar{z}}(z)}{z - z_0} dx dy = \int_{\partial D} \frac{f(z)}{z - z_0} dz + 2\pi i f(z_0). \quad \spadesuit$$

21. LEMMA. If $z_0 \in D(R)$, then

$$\bar{z}_0 = -\frac{1}{\pi} \iint_{D(R)} \frac{1}{z - z_0} dx dy.$$

PROOF. Let $\overline{D(R)}$ be the closure of $D(R) \subset \mathbb{C}$. Applying Lemma 20 to $\bar{z}: \overline{D(R)} \rightarrow \mathbb{C}$ we have

$$\bar{z}_0 = \frac{1}{2\pi i} \int_{\partial \overline{D(R)}} \frac{\bar{z}}{z - z_0} dz - \frac{1}{\pi} \iint_{D(R)} \frac{1}{z - z_0} dx dy,$$

and

$$\int_{\partial \overline{D(R)}} \frac{\bar{z}}{z - z_0} dz = \int_{\partial \overline{D(R)}} \frac{R^2}{z(z - z_0)} dz = 0,$$

since the sum of the residues of $R^2/z(z - z_0)$ inside $\partial \overline{D(R)}$ is 0. \spadesuit

22. LEMMA. If $z_0 \in D(R)$, then

$$|z_0|^2 = -\frac{1}{\pi} \iint_{D(R)} \frac{z}{z - z_0} dx dy + R^2.$$

PROOF. Since $|z|^2 = z\bar{z}$, so that

$$\frac{\partial |z|^2}{\partial \bar{z}} = z,$$

Lemma 20 now gives

$$|z_0|^2 = \frac{R^2}{2\pi i} \int_{\partial D(R)} \frac{1}{z - z_0} dz - \frac{1}{\pi} \int_{D(R)} \frac{z}{z - z_0} dx dy,$$

and

$$\frac{R^2}{2\pi i} \int_{\partial D(R)} \frac{1}{z - z_0} dz = R^2. \diamond$$

And now one somewhat more technical lemma.

23. LEMMA. Let $0 < \varepsilon_1, \varepsilon_2 \leq 1$, with $\varepsilon_1 + \varepsilon_2 \neq 2$. Then there is a constant $c(\varepsilon_1, \varepsilon_2)$, not depending on R , such that

$$\iint_{D(R)} \frac{dx dy}{|z - z_1|^{2-\varepsilon_1} \cdot |z - z_2|^{2-\varepsilon_2}} \leq c(\varepsilon_1, \varepsilon_2) \cdot \frac{1}{|z_1 - z_2|^{2-\varepsilon_1-\varepsilon_2}}$$

for all $z_1, z_2 \in D(R)$ with $z_1 \neq z_2$.

PROOF. Let $|z_1 - z_2| = 2\delta$ and define

D_1 = disc of radius δ around z_1

D_2 = disc of radius δ around z_2

$D_3 = D(R) - (D_1 \cup D_2)$.

Clearly

$$\begin{aligned} \iint_{D_1} \frac{dx dy}{|z - z_1|^{2-\varepsilon_1} \cdot |z - z_2|^{2-\varepsilon_2}} &\leq \frac{1}{\delta^{2-\varepsilon_2}} \iint_{D_1} \frac{dx dy}{|z - z_1|^{2-\varepsilon_1}} \\ &= \frac{1}{\delta^{2-\varepsilon_2}} \int_0^{2\pi} \int_0^\delta \frac{1}{r^{2-\varepsilon_1}} \cdot r dr d\theta && \text{using polar} \\ &= \frac{1}{\delta^{2-\varepsilon_2}} \cdot 2\pi \cdot \int_0^\delta r^{\varepsilon_1-1} dr && \text{coordinates} \\ &= \frac{1}{\delta^{2-\varepsilon_2}} \cdot 2\pi \cdot \frac{\delta^{\varepsilon_1}}{\varepsilon_1} = \frac{2\pi}{\varepsilon_1} \cdot \frac{1}{\delta^{2-\varepsilon_1-\varepsilon_2}}. \end{aligned}$$

Similarly, the integral over D_2 is

$$\leq \frac{2\pi}{\varepsilon_2} \cdot \frac{1}{\delta^{2-\varepsilon_1-\varepsilon_2}}.$$

These bounds both have the desired form

$$c(\varepsilon_1, \varepsilon_2) \cdot \frac{1}{|z_1 - z_2|^{2-\varepsilon_1-\varepsilon_2}}.$$

Now we always have

$$|z - z_1| \leq |z - z_2| + |z_1 - z_2| = |z - z_2| + 2\delta,$$

and consequently

$$\frac{|z - z_1|}{|z - z_2|} \leq 1 + \frac{2\delta}{|z - z_2|} \quad z \neq z_2.$$

So on D_3 (in fact on $\mathbb{R}^2 - D_2$) we have

$$\frac{|z - z_1|}{|z - z_2|} \leq 1 + \frac{2\delta}{\delta} = 3.$$

So

$$\begin{aligned} \iint_{D_3} \frac{dx \, dy}{|z - z_1|^{2-\varepsilon_1} \cdot |z - z_2|^{2-\varepsilon_2}} &= \iint_{D_3} \left| \frac{z - z_1}{z - z_2} \right|^{2-\varepsilon_2} \cdot \frac{dx \, dy}{|z - z_1|^{4-\varepsilon_1-\varepsilon_2}} \\ &\leq 3^{2-\varepsilon_2} \iint_{D_3} \frac{dx \, dy}{|z - z_1|^{4-\varepsilon_1-\varepsilon_2}} \\ &\leq 3^{2-\varepsilon_2} \iint_{\mathbb{R}^2 - D_1} \frac{dx \, dy}{|z - z_1|^{4-\varepsilon_1-\varepsilon_2}} \\ &\leq 3^{2-\varepsilon_2} \int_0^{2\pi} \int_\delta^\infty r^{\varepsilon_1+\varepsilon_2-3} \, dr \quad \text{using polar} \\ &\quad \text{coordinates} \\ &\quad \text{around } z_1 \\ &= 3^{2-\varepsilon_2} \cdot 2\pi \cdot \frac{1}{2-\varepsilon_1-\varepsilon_2} \cdot \delta^{\varepsilon_1+\varepsilon_2-2}, \end{aligned}$$

which is again of the desired form. ♦

We are now ready to give the precise formulation of (A), which includes three inequalities that are essential for proving that the equivalent integral equation can be solved.

24. PROPOSITION. Let $f: D(R) \rightarrow \mathbb{C}$ satisfy

$$\begin{aligned} |f(z)| &\leq M & z \in D(R) \\ |f(z_1) - f(z_2)| &\leq K|z_1 - z_2|^\alpha & z_1, z_2 \in D(R). \end{aligned}$$

Define

$$F(z_0) = -\frac{1}{\pi} \iint_{D(R)} \frac{f(z)}{z - z_0} dx dy, \quad z_0 \in D(R).$$

Then

$$\begin{aligned} \text{(a)} \quad & F_{\bar{z}}(z_0) = f(z_0) \\ \text{(b)} \quad & F_z(z_0) = -\frac{1}{\pi} \iint_{D(R)} \frac{f(z) - f(z_0)}{(z - z_0)^2} dx dy. \end{aligned}$$

Moreover for all $z_0, z_1, z_2 \in D(R)$ we have

$$\begin{aligned} \text{(c)} \quad & |F(z_0)| \leq 4RM \\ \text{(d)} \quad & |F_z(z_0)| \leq \frac{2^{\alpha+1}}{\alpha} R^\alpha K \\ \text{(e)} \quad & |F_z(z_1) - F_z(z_2)| \leq CK|z_1 - z_2|^\alpha, \end{aligned}$$

where C is a constant that *does not depend on R , or on the function f .*

PROOF. For fixed z_0 , let

$$\tilde{F}(z) = F(z) - f(z_0)\bar{z},$$

so that by Lemma 21

$$\tilde{F}(z') = -\frac{1}{\pi} \iint_{D(R)} \frac{f(z) - f(z_0)}{z - z'} dx dy.$$

We claim that the complex derivative $\tilde{F}'(z_0)$ exists and that in fact

$$\tilde{F}'(z_0) = -\frac{1}{\pi} \iint_{D(R)} \frac{f(z) - f(z_0)}{(z - z_0)^2} dx dy.$$

To prove this we have to show that as $h \rightarrow 0$, the same is true of

$$\begin{aligned}
& \left| \frac{\tilde{F}(z_0 + h) - \tilde{F}(z_0)}{h} + \frac{1}{\pi} \iint_{D(R)} \frac{f(z) - f(z_0)}{(z - z_0)^2} dx dy \right| \\
&= \left| -\frac{1}{\pi h} \iint_{D(R)} [f(z) - f(z_0)] \cdot \left\{ \frac{1}{z - z_0 - h} - \frac{1}{z - z_0} \right\} dx dy \right. \\
&\quad \left. + \frac{1}{\pi} \iint_{D(R)} \frac{f(z) - f(z_0)}{(z - z_0)^2} dx dy \right| \\
&= \left| -\frac{1}{\pi} \iint_{D(R)} \frac{f(z) - f(z_0)}{(z - z_0 - h)(z - z_0)} + \frac{1}{\pi} \iint_{D(R)} \frac{f(z) - f(z_0)}{(z - z_0)^2} dx dy \right| \\
&= \frac{1}{\pi} \left| \iint_{D(R)} \frac{f(z) - f(z_0)}{z - z_0} \left\{ \frac{1}{z - z_0 - h} - \frac{1}{z - z_0} \right\} dx dy \right| \\
&= \frac{|h|}{\pi} \left| \iint_{D(R)} \frac{f(z) - f(z_0)}{(z - z_0)^2(z - z_0 - h)} dx dy \right| \\
&\leq \frac{|h|}{\pi} \iint_{D(R)} \frac{|f(z) - f(z_0)|}{|z - z_0|^2 |z - z_0 - h|} dx dy \\
&\leq \frac{K|h|}{\pi} \iint_{D(R)} \frac{|z - z_0|^\alpha}{|z - z_0|^2 |z - z_0 - h|} dx dy \\
&= \frac{K|h|}{\pi} \iint_{D(R)} \frac{dx dy}{|z - z_0|^{2-\alpha} |z - z_0 - h|} \\
&\leq \frac{K}{\pi} |h| \cdot c(\alpha, 1) \cdot |h|^{\alpha+1-2} \quad \text{by Lemma 23} \\
&= \frac{K}{\pi} c(\alpha, 1) \cdot |h|^\alpha.
\end{aligned}$$

This indeed approaches 0 as $h \rightarrow 0$.

Now since the complex derivative $\tilde{F}'(z_0)$ exists for all $z_0 \in D(R)$, the ordinary partials F_x, F_y exist, and hence \tilde{F}_z and $\tilde{F}_{\bar{z}}$ exist. Moreover, since \tilde{F} is complex analytic, from the definition of \tilde{F} we obtain

$$0 = \tilde{F}_{\bar{z}}(z_0) = F_{\bar{z}}(z_0) - f(z_0) \cdot 1,$$

which proves (a). Furthermore

$$\tilde{F}'(z_0) = \tilde{F}_z(z_0) = F_z(z_0) - 0,$$

which proves (b).

To prove (c), we note that

$$\begin{aligned} |F(z_0)| &\leq \frac{M}{\pi} \iint_{D(R)} \frac{1}{|z - z_0|} dx dy \\ &\leq \frac{M}{\pi} \iint_D \frac{1}{|z - z_0|} dx dy && \text{where } D \supset D(R) \text{ is the disc} \\ &= \frac{M}{\pi} \int_0^{2\pi} \int_0^{2R} \frac{1}{r} \cdot r dr d\theta && \text{using polar} \\ &= 4RM. && \text{coordinates} \\ & && \text{around } z_0 \end{aligned}$$

Similarly, for (d) we have

$$\begin{aligned} |F_z(z_0)| &= \left| \frac{1}{\pi} \iint_{D(R)} \frac{|f(z) - f(z_0)|}{|z - z_0|^2} dx dy \right| && \text{by (b)} \\ &\leq \frac{K}{\pi} \iint_{D(R)} \frac{1}{|z - z_0|^{2-\alpha}} dx dy \\ &\leq \frac{K}{\pi} \iint_D \frac{1}{|z - z_0|^{2-\alpha}} dx dy \\ &= \frac{K}{\pi} \int_0^{2\pi} \int_0^{2R} \frac{1}{r^{2-\alpha}} r dr d\theta \\ &= \frac{2K(2R)^\alpha}{\alpha}. \end{aligned}$$

To prove (e) let z_1, z_2 be fixed, and define

$$\begin{cases} B = \frac{f(z_1) - f(z_2)}{z_1 - z_2} \\ \tilde{F}(z) = F(z) - Bz\bar{z}. \end{cases}$$

If we set

$$\tilde{f}(z) = f(z) - Bz,$$

then by Lemma 22 we have

$$\tilde{F}(z_0) = -\frac{1}{\pi} \iint_{D(R)} \frac{\tilde{f}(z)}{z - z_0} dx dy - BR^2.$$

So by (b) we have

$$\tilde{F}_z(z_0) = -\frac{1}{\pi} \iint_{D(R)} \frac{\tilde{f}(z) - \tilde{f}(z_0)}{(z - z_0)^2} dx dy.$$

Thus

$$\tilde{F}_z(z_1) - \tilde{F}_z(z_2) = -\frac{1}{\pi} \iint_{D(R)} \left\{ \frac{\tilde{f}(z) - \tilde{f}(z_1)}{(z - z_1)^2} - \frac{\tilde{f}(z) - \tilde{f}(z_2)}{(z - z_2)^2} \right\} dx dy.$$

But we easily check that

$$\tilde{f}(z_1) = \tilde{f}(z_2).$$

Therefore

$$\begin{aligned} & \tilde{F}_z(z_1) - \tilde{F}_z(z_2) \\ &= -\frac{1}{\pi} \iint_{D(R)} [\tilde{f}(z) - \tilde{f}(z_1)] \cdot \left\{ \frac{1}{(z - z_1)^2} - \frac{1}{(z - z_2)^2} \right\} dx dy \\ &= -\frac{1}{\pi} \iint_{D(R)} \frac{[\tilde{f}(z) - \tilde{f}(z_1)] \cdot (z_1 - z_2)(2z - z_1 - z_2)}{(z - z_1)^2(z - z_2)^2} dx dy \\ &= -\frac{1}{\pi} \iint_{D(R)} \frac{[\tilde{f}(z) - \tilde{f}(z_1)] \cdot (z_1 - z_2)[(z - z_1) + (z - z_2)]}{(z - z_1)^2(z - z_2)^2} dx dy. \end{aligned}$$

Now since

$$\begin{aligned} \tilde{f}(z) - \tilde{f}(z_1) &= f(z) - f(z_1) - B(z - z_1) \\ &\parallel \\ \tilde{f}(z) - \tilde{f}(z_2) &= f(z) - f(z_2) - B(z - z_2), \end{aligned}$$

we have

$$\begin{aligned}
 & [\tilde{f}(z) - \tilde{f}(z_1)][(z - z_1) + (z - z_2)] \\
 &= [f(z) - f(z_1) - B(z - z_1)](z - z_2) \\
 &\quad + [f(z) - f(z_2) - B(z - z_2)](z - z_1) \\
 &= [f(z) - f(z_1)](z - z_2) + [f(z) - f(z_2)](z - z_1) \\
 &\quad - 2B(z - z_1)(z - z_2).
 \end{aligned}$$

So we get

$$\begin{aligned}
 \tilde{F}_z(z_1) - \tilde{F}_z(z_2) &= -\frac{(z_1 - z_2)}{\pi} \iint_{D(R)} \frac{f(z) - f(z_1)}{(z - z_1)^2(z - z_2)} dx dy \\
 &\quad - \frac{(z_1 - z_2)}{\pi} \iint_{D(R)} \frac{f(z) - f(z_2)}{(z - z_1)(z - z_2)^2} dx dy \\
 &\quad + \frac{2B}{\pi} \iint_{D(R)} \frac{(z_1 - z_2)}{(z - z_1)(z - z_2)} dx dy \\
 &= I_1 + I_2 + I_3, \quad \text{say.}
 \end{aligned}$$

Now

$$\begin{aligned}
 |I_1| &\leq \frac{|z_1 - z_2|}{\pi} \iint_{D(R)} \frac{K}{|z - z_1|^{2-\alpha} \cdot |z - z_2|} dx dy \\
 &\leq \frac{|z_1 - z_2|}{\pi} \frac{K \cdot c(\alpha, 1)}{|z_1 - z_2|^{1-\alpha}} \quad \text{by Lemma 23} \\
 &= \frac{K \cdot c(\alpha, 1)}{\pi} |z_1 - z_2|^\alpha.
 \end{aligned}$$

Similarly,

$$|I_2| \leq \frac{K \cdot c(\alpha, 1)}{\pi} |z_1 - z_2|^\alpha.$$

Finally,

$$\begin{aligned}
 I_3 &= \frac{2B}{\pi} \iint_{D(R)} \left(\frac{1}{z - z_1} - \frac{1}{z - z_2} \right) dx dy \\
 &= 2B(\bar{z}_1 - \bar{z}_2) \quad \text{by Lemma 21,}
 \end{aligned}$$

so

$$|I_3| \leq 2|B| \cdot |z_1 - z_2|.$$

We have

$$|B| = \frac{|f(z_1) - f(z_2)|}{|z_1 - z_2|} \leq K|z_1 - z_2|^{\alpha-1}.$$

Therefore

$$|I_3| \leq 2K|z_1 - z_2|^\alpha.$$

Thus

$$\begin{aligned} |\tilde{F}_z(z_1) - \tilde{F}_z(z_2)| &\leq |I_1| + |I_2| + |I_3| \\ &\leq (\text{constant}) \cdot K \cdot |z_1 - z_2|^\alpha. \end{aligned}$$

From the definition of \tilde{F} we have

$$\tilde{F}_z(z) = F_z(z) - B\bar{z},$$

so we have

$$\begin{aligned} |F_z(z_1) - F_z(z_2)| &\leq (\text{constant}) \cdot K \cdot |z_1 - z_2|^\alpha + |B| \cdot |\bar{z}_1 - \bar{z}_2| \\ &\leq (\text{constant}) \cdot K \cdot |z_1 - z_2|^\alpha + K|z_1 - z_2|^{\alpha-1} \cdot |z_1 - z_2|, \\ &\quad \text{by the estimate for } |B| \text{ above} \\ &\leq CK|z_1 - z_2|^\alpha. \quad \spadesuit \end{aligned}$$

Instead of solving the equation

$$(*) \quad w_{\bar{z}} = \mu w_z.$$

or the equivalent integral equation, for reasons that will appear later we will instead solve the more general equation

$$(**) \quad w_{\bar{z}} = \mu w_z + \gamma w + \delta.$$

where μ, γ, δ are C^α and $|\mu(0)| < 1$; moreover, we will show that solutions exist with any given values for $w(0)$ and $w_z(0)$. There is no loss of generality in assuming that $\mu(0) = 0$:

25. LEMMACHEN. If the equation

$$(**) \quad w_{\bar{z}} = \mu w_z + \gamma w + \delta$$

has a $C^{1+\alpha}$ solution in a neighborhood of 0, with arbitrary values for $w(0)$ and $w_z(0)$, for all C^α functions μ, γ, δ with $\mu(0) = 0$, then it also has such $C^{1+\alpha}$ solutions for all C^α functions μ, γ, δ with $|\mu(0)| < 1$.

PROOF. For any function w , define \tilde{w} by

$$\tilde{w}(z) = w(z - \mu(0)\bar{z}),$$

so that

$$w(z) = \tilde{w}(z + \mu(0)\bar{z}).$$

The chain rule on page 320 gives

$$(1) \quad \begin{aligned} w_z(z) &= \tilde{w}_z + \tilde{w}_{\bar{z}} \cdot \overline{\mu(0)}, \\ w_{\bar{z}}(z) &= \tilde{w}_z \cdot \mu(0) + \tilde{w}_{\bar{z}}, \end{aligned}$$

where $\tilde{w}_z, \tilde{w}_{\bar{z}}$ are to be evaluated at $z + \mu(0)\bar{z}$. Therefore

$$(**) \quad w_{\bar{z}} = \mu w_z + \gamma w + \delta$$

if and only if

$$\mu(0) \cdot \tilde{w}_z + \tilde{w}_{\bar{z}} = \mu(z)[\tilde{w}_z + \overline{\mu(0)}\tilde{w}_{\bar{z}}] + \gamma(z)w(z) + \delta(z),$$

or

$$\begin{aligned} \tilde{w}_{\bar{z}} &= \left(\frac{\mu(z) - \mu(0)}{1 - \overline{\mu(0)}\mu(z)} \right) \tilde{w}_z + \frac{\gamma(z)}{1 - \overline{\mu(0)}\mu(z)} w(z) + \frac{\delta(z)}{1 - \overline{\mu(0)}\mu(z)} \\ &= \rho(z)\tilde{w}_{\bar{z}} + \sigma(z)w(z) + \tau(z), \quad \text{say,} \end{aligned}$$

where $\rho(0) = 0$. In this equation $\tilde{w}_{\bar{z}}, \tilde{w}_z$ are evaluated at $z + \overline{\mu(0)}z$. Replacing z by $z - \overline{\mu(0)}z$, we get the equivalent equation

$$(\widetilde{**}) \quad \tilde{w}_{\bar{z}}(z) = \rho(z - \overline{\mu(0)}z)\tilde{w}_{\bar{z}}(z) + \sigma(z - \overline{\mu(0)}z)\tilde{w}(z) + \tau(z - \overline{\mu(0)}z),$$

which is of the same form as $(**)$, with the coefficient of $\tilde{w}_{\bar{z}}$ being 0 at 0. So by hypothesis we can solve for a $C^{1+\alpha}$ function \tilde{w} with any desired initial values

$$\tilde{w}(0) = \tilde{a}, \quad \tilde{w}_z(0) = \tilde{b}.$$

This gives

$$w(0) = \tilde{w}(0) = \tilde{a},$$

while by equation (1)

$$w_z(0) = \tilde{w}_z(0) + \overline{\mu(0)}\tilde{w}_{\bar{z}}(0).$$

Using equation (**), we have

$$\tilde{w}_{\bar{z}}(0) = \sigma(0)\tilde{w}(0) + \tau(0) = \sigma(0) \cdot \tilde{a} + \tau(0),$$

so

$$w_z(0) = \tilde{b} + \overline{\mu(0)}[\sigma(0) \cdot \tilde{a} + \tau(0)].$$

So to solve (**) for

$$w(0) = a, \quad w_z(0) = b,$$

we just solve (**) for

$$\begin{aligned} \tilde{w}(0) &= a \\ \tilde{w}_z(0) &= b - \overline{\mu(0)}[\sigma(0)\tilde{a} + \tau(0)]. \quad \spadesuit \end{aligned}$$

Since we will be solving the general equation

$$(**) \quad w_{\bar{z}} = \mu w_z + \gamma w + \delta, \quad \mu(0) = 0,$$

we first want to find an integral equation equivalent to it. To do this we form

$$F(z_0) = -\frac{1}{\pi} \iint_{D(R)} \frac{\mu(z)w_z(z) + \gamma(z)w(z) + \delta(z)}{z - z_0} dx dy.$$

Proposition 24 gives

$$F_{\bar{z}} = \mu w_z + \gamma w + \delta = w_{\bar{z}} \quad \text{if } w \text{ satisfies } (**),$$

and hence $(w - F)_{\bar{z}} = 0$, so that

$$\begin{aligned} w(z_0) &= -\frac{1}{\pi} \iint_{D(R)} \frac{\mu(z)w_z(z)}{z - z_0} dx dy - \frac{1}{\pi} \iint_{D(R)} \frac{\gamma(z)w(z)}{z - z_0} dx dy \\ &\quad - \frac{1}{\pi} \iint_{D(R)} \frac{\delta(z)}{z - z_0} dx dy + g(z_0) \end{aligned}$$

for some complex analytic function g . Conversely, of course, if w satisfies this equation for a complex analytic g , then it satisfies (**). By complicating our integral equation, we can arrange that $w(0) = g(0)$; clearly we just have to add

$$\frac{1}{\pi} \iint_{D(R)} \frac{\mu(z)w_z(z)}{z} dx dy + \cdots$$

to the right hand side. Similarly, if we add

$$z \cdot \left\{ \frac{1}{\pi} \iint_{D(R)} \frac{\mu(z)w_z(z)}{z^2} + \cdots \right\}$$

to the right hand side, we will have $w_z(0) = g'(0)$; this follows from Proposition 24 (and the fact that $\mu(0) = 0$). So we see that we can solve (**) for w with any given values of $w(0), w_z(0)$ provided that we can solve the following equation for w , where g is any complex analytic function (actually it would suffice to solve it for functions of the form $g(z) = \tilde{a}z + \tilde{b}$):

$$\begin{aligned} w(z_0) &= -\frac{1}{\pi} \iint_{D(R)} \frac{\mu(z)w_z(z)}{z - z_0} dx dy - \frac{1}{\pi} \iint_{D(R)} \frac{\gamma(z)w(z)}{z - z_0} dx dy - \frac{1}{\pi} \iint_{D(R)} \frac{\delta(z)}{z - z_0} dx dy \\ &+ \frac{1}{\pi} \iint_{D(R)} \frac{\mu(z)w_z(z)}{z} dx dy + \frac{1}{\pi} \iint_{D(R)} \frac{\gamma(z)w(z)}{z} dx dy + \frac{1}{\pi} \iint_{D(R)} \frac{\delta(z)}{z} dx dy \\ &+ z_0 \left\{ \frac{1}{\pi} \iint_{D(R)} \frac{\mu(z)w_z(z)}{z^2} dx dy + \frac{1}{\pi} \iint_{D(R)} \frac{\gamma(z)w(z)}{z^2} dx dy + \frac{1}{\pi} \iint_{D(R)} \frac{\delta(z)}{z^2} dx dy \right\} \\ &+ g(z_0). \end{aligned}$$

Now the first integral involving δ is a $C^{1+\alpha}$ function Δ , for Proposition 24 shows that

$$\begin{aligned} \Delta_{\bar{z}} &= \delta && \text{which is } C^\alpha \text{ by assumption,} \\ \Delta_z &\text{ is } C^\alpha && \text{by part (e) of Proposition 24.} \end{aligned}$$

The other two integrals involving δ are just constants. So it certainly suffices

to show that we can solve the following equation for C^α functions μ, γ with $\mu(0) = 0$ and any $C^{1+\alpha}$ function h :

$$(I) \quad \begin{aligned} w(z_0) = & -\frac{1}{\pi} \iint_{D(R)} \frac{\mu(z)w_z(z)}{z - z_0} dx dy - \frac{1}{\pi} \iint_{D(R)} \frac{\gamma(z)w(z)}{z - z_0} dx dy \\ & + \frac{1}{\pi} \iint_{D(R)} \frac{\mu(z)w_z(z)}{z} dx dy + \frac{1}{\pi} \iint_{D(R)} \frac{\gamma(z)w(z)}{z} dx dy \\ & + z_0 \left\{ \frac{1}{\pi} \iint_{D(R)} \frac{\mu(z)w_z(z)}{z^2} dx dy + \frac{1}{\pi} \iint_{D(R)} \frac{\gamma(z)w(z)}{z^2} dx dy \right\} \\ & + h(z_0). \end{aligned}$$

The integral equation (I) will be solved by the only method available to us, namely, the method of successive approximation, which we have always formulated in terms of the Contraction Lemma (I.5-1). First we need to concoct the right space of functions to work with. Consider first the set

$$H(R, \alpha) = \{C^\alpha \text{ functions } w: D(R) \rightarrow \mathbb{C}\}.$$

For $w \in H(R, \alpha)$ we define

$$\|w\|_R = \sup_{z \in D(R)} |w(z)| + R^\alpha \cdot \sup_{\substack{z_1, z_2 \in D(R) \\ z_1 \neq z_2}} \frac{|w(z_1) - w(z_2)|}{|z_1 - z_2|^\alpha}.$$

The first term $\sup |w(z)|$ insures that $w_n \rightarrow 0$ uniformly if $\|w_n\|_R \rightarrow 0$. The term $\sup |w(z_1) - w(z_2)|/|z_1 - z_2|^\alpha$ is simply the “best” constant K in the definition of w being C^α ; the fudge factor R^α is reasonable, for it insures that

$$\|w\|_R = \|\tilde{w}\|_1 \quad \text{where} \quad \tilde{w}(z) = w(Rz).$$

It is easy to check that

$$\begin{aligned} \|w\|_R &> 0 && \text{for } w \neq 0, \\ \|\lambda w\|_R &= |\lambda| \cdot \|w\|_R && \lambda \in \mathbb{R}, \\ \|w_1 + w_2\|_R &\leq \|w_1\|_R + \|w_2\|_R. \end{aligned}$$

So we obtain a metric on $H(R, \alpha)$ by defining

$$\text{distance from } w_1 \text{ to } w_2 = \|w_1 - w_2\|_R,$$

and it is easy to see that $H(R, \alpha)$ is complete in this metric. Finally, it is easily checked that if $w_1, w_2 \in H(R, \alpha)$, then

$$\|w_1 w_2\|_R \leq \|w_1\|_R \cdot \|w_2\|_R.$$

Next consider the set

$$H(R, \alpha + 1) = \{C^{\alpha+1} \text{ functions } w: D(R) \rightarrow \mathbb{C}\}.$$

For $w \in H(R, \alpha + 1)$ we define

$$\|w\|_R = \sup_{z \in D(R)} |w(z)| + R \cdot \|w_z\|_R + R \cdot \|w_{\bar{z}}\|_R.$$

It is once again easy to check that

$$\|w\|_R > 0 \quad \text{for } w \neq 0$$

$$\|\lambda w\|_R = |\lambda| \cdot \|w\|_R$$

$$\|w_1 + w_2\|_R \leq \|w_1\|_R + \|w_2\|_R,$$

and that $H(R, \alpha + 1)$ is a complete metric space with respect to the metric

$$\text{distance from } w_1 \text{ to } w_2 = \|w_1 - w_2\|_R.$$

Consider, for the moment, a function $f: (-R, R) \rightarrow \mathbb{R}$, and suppose that

$$R^{\alpha+1} \cdot \frac{|f'(x_1) - f'(x_2)|}{|x_1 - x_2|^\alpha} \leq K.$$

Defining

$$g(s) = f(x_1 + s(x_2 - x_1)) - f(x_2 + s(x_1 - x_2)),$$

we have

$$g(0) = f(x_1) - f(x_2), \quad g(1) = f(x_2) - f(x_1).$$

So the mean value theorem gives

$$\begin{aligned} 2[f(x_2) - f(x_1)] &= \frac{g(1) - g(0)}{1 - 0} = g'(\xi) & \xi \in (0, 1) \\ &= (x_2 - x_1) \cdot [f'(\eta_1) - f'(\eta_2)] & \eta_1, \eta_2 \in (x_1, x_2). \end{aligned}$$

Thus

$$\begin{aligned} R^\alpha |f(x_1) - f(x_2)| &\leq \frac{R^\alpha |x_1 - x_2|}{2} \cdot \frac{K |\eta_1 - \eta_2|^\alpha}{R^{\alpha+1}} \\ &= \frac{K}{2} \frac{|x_1 - x_2|}{R} \cdot |\eta_1 - \eta_2|^\alpha \\ &\leq K \cdot |x_1 - x_2|^\alpha, \end{aligned}$$

or finally

$$R^\alpha \frac{|f(x_1) - f(x_2)|}{|x_1 - x_2|^\alpha} \leq K.$$

For functions $w: D(R) \rightarrow \mathbb{C}$ there is a similar argument, using Taylor's formula to estimate $|g(1) - g(0)|$. The answer involves the derivative Dw , which can be expressed in terms of w_z and $w_{\bar{z}}$. From this argument we easily see that there is an inequality of the form

$$\|w\|_R \leq (\text{constant}) \cdot |||w|||_R.$$

26. PROPOSITION. Let μ, γ be C^α functions in a neighborhood of 0 with $\mu(0) = 0$, and let h be $C^{\alpha+1}$ in a neighborhood of 0. Then for sufficiently small $R > 0$ there is a $C^{\alpha+1}$ function $w: D(R) \rightarrow \mathbb{C}$ satisfying (I) for all $z_0 \in D(R)$.

PROOF. We suppose that μ, γ are C^α in $D(R_0)$ for some $R_0 \leq 1$, and we will henceforth consider only $R \leq R_0$. For $w \in H(R, \alpha + 1)$, define the function Sw on $D(R)$ by setting $(Sw)(z_0)$ equal to the right side of (I) without the $h(z_0)$: we will abbreviate this expression by

$$\begin{aligned} (Sw)(z_0) = & I_1(z_0) + I_2(z_0) \\ & + I_3(z_0) + I_4(z_0) \\ & + z_0\{I_5(z_0) + I_6(z_0)\}. \end{aligned}$$

We make the crucial

CLAIM. There is a constant C' , depending only on α , and not on R , such that

$$|||Sw|||_R \leq C' \cdot R^\alpha \cdot |||w|||_R$$

for all $w \in H(R, \alpha + 1)$.

Assuming this Claim for the moment, the remainder of the proof goes as follows. Since $R^\alpha \rightarrow 0$ as $R \rightarrow 0$, there is clearly some R_* such that for all $R \leq R_*$ we have

$$|||Sw|||_R \leq C'' \cdot |||w|||_R,$$

where C'' is a constant with

$$C'' < 1, \quad \frac{|||h|||_R}{3}.$$

Define $T : H(R, \alpha + 1) \rightarrow H(R, \alpha + 1)$ by

$$Tw = Sw + h.$$

If $R \leq R_*$, then for all w with

$$\|w\|_R \leq \frac{3}{2} \|h\|_R$$

we have

$$\begin{aligned} \|Tw\|_R &= \|Sw + h\|_R \leq \|Sw\|_R + \|h\|_R \\ &\leq \frac{\|h\|_R}{3} \cdot \|w\|_R + \|h\|_R \\ &\leq \frac{1}{2} \|h\|_R + \|h\|_R \\ &= \frac{3}{2} \|h\|_R. \end{aligned}$$

Thus, for $R \leq R_*$, the map T takes the complete metric space

$$M = \left\{ w \in H(R, \alpha + 1) : \|w\|_R \leq \frac{3}{2} \|h\|_R \right\}$$

into itself. Moreover, the map $T : M \rightarrow M$ is a contraction, for

$$\begin{aligned} \|Tw_1 - Tw_2\|_R &= \|Sw_1 - Sw_2\|_R \\ &= \|S(w_1 - w_2)\|_R \leq C'' \cdot \|w_1 - w_2\|_R. \end{aligned}$$

By the Contraction Lemma, there is some $w \in M$ with

$$w = Tw = Sw + h,$$

which is precisely the equation we want.

To prove the Claim we will use all the information in Lemma 24. First we want to show that

$$\|I_1\|_R \leq (\text{constant}) \cdot R^\alpha \cdot \|w\|_R,$$

where the constant is independent of R . It clearly suffices to prove the same inequality for each of

$$\sup |I_1(z)|, \quad R \cdot \|(I_1)_z\|_R, \quad R \cdot \|(I_1)_{\bar{z}}\|_R.$$

Let L be a number such that

$$|\mu(z_1) - \mu(z_2)| \leq L \cdot |z_1 - z_2|^\alpha, \quad z_1, z_2 \in D(R_0).$$

Since $\mu(0) = 0$, it follows that

$$|\mu(z)| \leq L R^\alpha, \quad z \in D(R), \quad R \leq R_0$$

and therefore that

$$\|\mu\|_R \leq 2L R^\alpha.$$

Thus for all $z, z_1, z_2 \in D(R)$ we have

$$\begin{aligned} (1) \quad |\mu(z)w_z(z)| &\leq \|\mu w_z\|_R \leq \|\mu\|_R \cdot \|w_z\|_R \\ &\leq 2L R^\alpha \cdot \frac{\|w\|_R}{R} \\ &= 2L R^{\alpha-1} \cdot \|w\|_R, \\ (2) \quad \frac{|\mu(z_1)w_z(z_1) - \mu(z_2)w_z(z_2)|}{|z_1 - z_2|^\alpha} &\leq \frac{\|\mu w_z\|_R}{R^\alpha} \leq \frac{\|\mu\|_R \cdot \|w_z\|_R}{R^\alpha} \\ &\leq \frac{2L R^\alpha \cdot \|w\|_R}{R^\alpha \cdot R} \\ &= \frac{2L}{R} \cdot \|w\|_R. \end{aligned}$$

We can now apply the inequalities of Proposition 24. Inequality (c) gives

$$\begin{aligned} (3) \quad |I_1(z)| &\leq 4R \cdot 2L R^{\alpha-1} \cdot \|w\|_R \\ &= 8L \cdot R^\alpha \cdot \|w\|_R, \end{aligned}$$

which is the desired inequality for $\sup |I_1(z)|$. Inequalities (d) and (e) give

$$\begin{aligned} (4) \quad R \cdot |(I_1)_z(z)| &\leq R \frac{2^{\alpha+1}}{\alpha} R^\alpha \cdot \frac{2L}{R} \|w\|_R \\ &= \frac{2^{\alpha+2}}{\alpha} L \cdot R^\alpha \cdot \|w\|_R \end{aligned}$$

$$\begin{aligned} (5) \quad R^{\alpha+1} \cdot \frac{|(I_1)_z(z_1) - (I_1)_z(z_2)|}{|z_1 - z_2|^\alpha} &\leq R^{\alpha+1} \cdot C \cdot \frac{2L}{R} \|w\|_R \\ &= 2CL \cdot R^\alpha \cdot \|w\|_R; \end{aligned}$$

these give the desired inequality for $R \cdot \|(I_1)_z\|_R$. Finally, since $(I_1)_{\bar{z}} = \mu z$, the necessary inequalities for $R \cdot \|(I_1)_{\bar{z}}\|_R$ follow immediately from (1), (2). We have

therefore shown that

$$\|I_1\|_R \leq (\text{constant}) \cdot R^\alpha \cdot \|w\|_R.$$

Now consider I_2 . We first note that for $z \in D(R)$ we have

$$\begin{aligned} |\gamma(z)w(z)| &\leq \|\gamma w\|_R \leq \|\gamma\|_R \cdot \|w\|_R \\ &\leq \|\gamma\|_{R_0} \cdot (\text{constant}) \cdot \|w\|_R \quad (\text{see page 338}). \end{aligned}$$

This is a *stronger* inequality than (1): since $0 < R \leq 1$ and $0 < \alpha < 1$ we have $1 \leq R^{\alpha-1}$, so we can write

$$(1') \quad |\gamma(z)w(z)| \leq (\text{constant}) \cdot R^{\alpha-1} \cdot \|w\|_R.$$

Similarly, if $z_1, z_2 \in D(R)$, then

$$\begin{aligned} (2') \quad \frac{|\gamma(z_1)w(z_1) - \gamma(z_2)w(z_2)|}{|z_1 - z_2|^\alpha} &\leq \frac{\|\gamma w\|_R}{R^\alpha} \leq \frac{\|\gamma\|_R \cdot \|w\|_R}{R^\alpha} \\ &\leq \frac{\|\gamma\|_{R_0}}{R^\alpha} \cdot (\text{constant}) \cdot \|w\|_R \\ &\leq \frac{\text{constant}}{R} \cdot \|w\|_R. \end{aligned}$$

Now (1'), (2') give the inequality

$$\|I_2\|_R \leq (\text{constant}) \cdot R^\alpha \cdot \|w\|_R$$

in the same way that (1), (2) gave the inequality for $\|I_1\|_R$.

Since I_3 is just a constant, $I_3(z) = I_1(0)$, we have

$$\begin{aligned} \|I_3\|_R &= \|I_1(0)\|_R = |I_1(0)| \leq \sup_{z \in D(R)} |I_1(z)| \\ &\leq \|I_1\|_R \leq (\text{constant}) \cdot R^\alpha \cdot \|w\|_R. \end{aligned}$$

Similarly for I_4 .

As for the term $zI_5(z) = z(I_1)_z(0)$, we have

$$\begin{aligned} |z(I_1)_z(0)| &\leq |z| \cdot |(I_1)_z(0)| \\ &\leq R \cdot \frac{\|I_1\|_R}{R} = \|I_1\|_R \\ &\leq (\text{constant}) \cdot R^\alpha \cdot \|w\|_R, \\ R \cdot \|\{z \cdot (I_1)_z(0)\}_z\|_R &= R \cdot \|(I_1)_z(0)\|_R \\ &= R \cdot |(I_1)_z(0)| \\ &\leq (\text{constant}) \cdot R^\alpha \cdot \|w\|_R. \quad \text{as above.} \end{aligned}$$

Thus $\|z(I_1)_z(0)\|_R \leq (\text{constant}) \cdot R^\alpha \cdot \|w\|_R$, and the term $zI_6(z)$ works exactly the same. ♦

27. COROLLARY. If μ, γ, δ are C^α functions in a neighborhood of 0, with $|\mu(0)| < 1$, and $a, b \in \mathbb{C}$ are any two complex numbers, then there is a $C^{\alpha+1}$ function w in a neighborhood of 0 such that

$$\begin{aligned} w_{\bar{z}} &= \mu w_z + \gamma w + \delta \\ (**) \quad w(0) &= a \\ w_z(0) &= b. \end{aligned}$$

In particular, there is a $C^{1+\alpha}$ isothermal coordinate system around any point of a surface with a C^α metric.

PROOF. Proposition 26 and Lemmacheen 25. ♦

Our next task is to show that if μ, γ, δ in Corollary 27 are $C^{n+\alpha}$, then there is a solution w of $(**)$ which is $C^{n+1+\alpha}$. First a technical lemma.

28. LEMMA. If f is $C^{n+\alpha}$ ($n \geq 1$) on $D(R)$ and we define

$$F(z_0) = -\frac{1}{\pi} \iint_{D(R)} \frac{f(z)}{z - z_0} dx dy, \quad z_0 \in D(R),$$

then F is $C^{n+1+\alpha}$.

PROOF. Induction on n . Consider first the case $n = 1$. By Proposition 24 we have $F_{\bar{z}} = f$, so $F_{\bar{z}}$ is $C^{1+\alpha}$. We just have to show that F_z is $C^{1+\alpha}$, since this then implies that F_x, F_y are $C^{1+\alpha}$, so that F is $C^{2+\alpha}$. Now we easily check that

$$\frac{\partial}{\partial z} \log |z - z_0|^2 = \frac{1}{z - z_0},$$

and therefore

$$F(z_0) = -\frac{1}{\pi} \iint_{D(R)} \frac{\partial}{\partial z} (f \log |z - z_0|^2) dx dy + \frac{1}{\pi} \iint_{D(R)} f_z \log |z - z_0|^2 dx dy.$$

Using the Remark after Lemma 19, we write this as

$$F(z_0) = \frac{1}{2\pi i} \int_{\partial \overline{D(R)}} f \log |z - z_0|^2 d\bar{z} + \frac{1}{\pi} \iint_{D(R)} f_z \log |z - z_0|^2 dx dy.$$

We can now differentiate under the integral signs to obtain

$$(1) \quad F_z(z_0) = \frac{1}{2\pi i} \int_{\partial D(R)} \frac{f(z)}{z - z_0} d\bar{z} + \frac{1}{\pi} \iint_{D(R)} \frac{f_z(z)}{z - z_0} dx dy.$$

The first integral is C^∞ (since we can keep differentiating under the integral sign); the second is $C^{1+\alpha}$ by Proposition 24.

Now suppose the result holds for $C^{n+\alpha}$ functions, and let f be $C^{n+1+\alpha}$. We still have $F_{\bar{z}} = f$, so that $F_{\bar{z}}$ is $C^{n+1+\alpha}$, and we also have equation (1), in which the first integral is C^∞ . Now f_z is $C^{n+\alpha}$, so by the induction assumption, the second integral is $C^{n+1+\alpha}$. Thus F_z is $C^{n+1+\alpha}$, so F is $C^{n+2+\alpha}$. ♦

29. PROPOSITION. If μ, γ, δ are $C^{n+\alpha}$ functions in a neighborhood of 0, with $|\mu(0)| < 1$, and $a, b \in \mathbb{C}$ are any two complex numbers, then there is a $C^{n+1+\alpha}$ function w in a neighborhood of 0 such that

$$\begin{aligned} w_{\bar{z}} &= \mu w_z + \gamma w + \delta \\ (**) \quad w(0) &= a \\ w_z(0) &= b. \end{aligned}$$

In particular, there is a $C^{n+1+\alpha}$ isothermal coordinate system around any point of a surface with a $C^{n+\alpha}$ metric.

PROOF. Induction on n . The case $n = 0$ is Corollary 26. Now suppose the result is true for n , and let μ, γ, δ be $C^{n+1+\alpha}$.

Case 1. $\gamma = 0$. The motivation for the proof is the following. If w satisfies

$$(1) \quad w_{\bar{z}} = \mu w_z + \delta,$$

then we should have

$$(w_z)_{\bar{z}} = w_{\bar{z}z} = \mu(w_z)_z + \mu_z w_z + \delta_z.$$

So we first solve this equation for w_z . To be precise, we note that μ, μ_z, δ_z are $C^{n+\alpha}$, so since the result is assumed true for n , there is a function f satisfying

$$(2) \quad f_{\bar{z}} = \mu f_z + \mu_z f + \delta_z$$

in some disc $D(R)$; moreover, we can obtain any desired values for $f(0)$ and $f_z(0)$. [Notice that equation (2) contains f explicitly even though equation (1) does not contain w explicitly.] Define W by

$$\bar{W}(z_0) = -\frac{1}{\pi} \iint_{D(R)} \frac{\bar{f}(z)}{z - z_0} dx dy.$$

Then W is $C^{n+2+\alpha}$ by Lemma 28, and by Proposition 24 we have

$$\bar{f}(z_0) = \bar{W}_{\bar{z}}(z_0) = \overline{W_z(z_0)} \implies f(z_0) = W_z(z_0).$$

So

$$\begin{aligned} (W_{\bar{z}})_z &= W_{z\bar{z}} = \bar{f}_z = \mu f_z + \mu_z f + \delta_z \quad \text{by (1)} \\ &= (\mu f)_z + \delta_z = (\mu W_z)_z + \delta_z. \end{aligned}$$

Hence $(W_{\bar{z}} - \mu W_z - \delta)_z = 0$. This means that we can write

$$(3) \quad W_{\bar{z}}(z) - \mu(z)W_z(z) - \delta(z) = g(\bar{z}),$$

where g is complex analytic. Let G be a complex analytic function with $G_{\bar{z}}(\bar{z}) = g(\bar{z})$, and let

$$w(z) = W(z) - G(\bar{z}).$$

Then

$$\begin{aligned} w_z &= W_z - 0 \\ w_{\bar{z}}(z) &= W_{\bar{z}}(z) - g(\bar{z}) = \mu(z)W_z(z) + \delta(z) \quad \text{by (3)} \\ &= \mu(z)w_z(z) + \delta(z). \end{aligned}$$

Thus w is a $C^{n+2+\alpha}$ solution of our equation. We also have

$$\begin{aligned} w(0) &= W(0) - G(0) \\ w_z(0) &= W_z(0) = f(0). \end{aligned}$$

So we obtain the condition $w_z(0) = b$ by choosing a solution f of (2) with $f(0) = b$. We can obtain $w(0) = a$ since G is only determined up to a constant.

Case 2. General case. We look for a solution of the form $w = e^\lambda \sigma$. We find that the equation

$$(4) \quad w_{\bar{z}} = \mu w_z + \gamma w + \delta$$

is equivalent to

$$\sigma_{\bar{z}} + \lambda_{\bar{z}}\sigma = \mu\sigma_z + \mu\lambda_z\sigma + \gamma\sigma + e^{-\lambda}\delta,$$

or

$$\sigma(\lambda_{\bar{z}} - \mu\lambda_z - \gamma) + \sigma_{\bar{z}} = \mu\sigma_z + e^{-\lambda}\delta.$$

By Case 1, there are $C^{n+2+\alpha}$ functions λ, σ satisfying

$$\begin{aligned} \lambda_{\bar{z}} &= \mu\lambda_z + \gamma; & \lambda(0) &= 0, & \lambda_z(0) &= 0 \\ \sigma_{\bar{z}} &= \mu\sigma_z + e^{-\lambda}\delta; & \sigma(0) &= a, & \sigma_z(0) &= b. \end{aligned}$$

Then $w = e^\lambda \sigma$ is $C^{n+2+\alpha}$ and satisfies (4), and $w(0) = a$, $w_z(0) = b$. ❖

Notice that Proposition 29 does not give a C^∞ isothermal coordinate system in the C^∞ case; for although the equation $w_{\bar{z}} = \mu w_z$ will have $C^{n+1+\alpha}$ solutions for all n , these solutions might be defined on smaller and smaller neighborhoods of 0. But this is now easy to take care of. First let us note that if (u, v) is an isothermal coordinate system, and $f: \mathbb{C} \rightarrow \mathbb{C}$ is complex analytic, with f' never 0, then $f \circ (u, v)$ is also an isothermal coordinate system, since f is angle preserving. We can also prove this from our equation $w_{\bar{z}} = \mu w_z$, for since $f_{\bar{z}} = 0$, the chain rule gives

$$\begin{aligned}(f \circ w)_z &= (f_z \circ w) \cdot w_z \\ (f \circ w)_{\bar{z}} &= (f_z \circ w) \cdot w_{\bar{z}},\end{aligned}$$

and hence we have $(f \circ w)_{\bar{z}} = \mu \cdot (f \circ w)_z$. This argument can also be reversed, allowing us to prove

30. PROPOSITION. If μ is a $C^{n+\alpha}$ function with $|\mu| < 1$, and w is any solution of

$$(*) \quad w_{\bar{z}} = \mu w_z,$$

then w is $C^{n+1+\alpha}$. So if μ is C^∞ , any solution w is also C^∞ .

In particular, there is a C^∞ isothermal coordinate system around any point of a surface with a C^∞ metric.

PROOF. We know that around any point there is *some* $C^{n+1+\alpha}$ solution σ of $(*)$ which has an inverse around that point. So we can write

$$(1) \quad w = f \circ \sigma$$

for some f . Then the chain rule gives

$$\begin{aligned}w_z &= (f_z \circ \sigma) \cdot \sigma_z + (f_{\bar{z}} \circ \sigma) \bar{\sigma}_z \\ w_{\bar{z}} &= (f_z \circ \sigma) \cdot \sigma_{\bar{z}} + (f_{\bar{z}} \circ \sigma) \bar{\sigma}_{\bar{z}}.\end{aligned}$$

Since w is a solution of $(*)$, we have

$$(f_z \circ \sigma) \sigma_{\bar{z}} + (f_{\bar{z}} \circ \sigma) \bar{\sigma}_{\bar{z}} = \mu [(f_z \circ \sigma) \sigma_z + (f_{\bar{z}} \circ \sigma) \bar{\sigma}_z].$$

Since σ is a solution, this leads to

$$(2) \quad (f_{\bar{z}} \circ \sigma) [\bar{\sigma}_{\bar{z}} - \mu \bar{\sigma}_z] = 0.$$

Since $\sigma_{\bar{z}} = \mu\sigma_z$ implies that

$$\bar{\sigma}_z = \overline{(\sigma_{\bar{z}})} = \bar{\mu}\overline{(\sigma_z)} = \bar{\mu}\bar{\sigma}_{\bar{z}},$$

we see that

$$\begin{aligned}\bar{\sigma}_{\bar{z}} - \mu\bar{\sigma}_z &= \bar{\sigma}_{\bar{z}} - \mu\bar{\mu}\bar{\sigma}_{\bar{z}} \\ &= \bar{\sigma}_{\bar{z}}(1 - |\mu|^2).\end{aligned}$$

This is non-zero, since $|\mu| < 1$, and σ has non-zero Jacobian at the point in question. It follows from (2) that $f_{\bar{z}} = 0$, i.e., f is analytic. Then (1) shows that w must be $C^{n+1+\alpha}$ too. ♦

ADDENDUM 2

IMMERSED SPHERES WITH
CONSTANT MEAN CURVATURE

Let $f: U \rightarrow M$ be an immersion (for $U \subset \mathbb{R}^2$ open) which is conformal, so that the components E, F, G of I_f satisfy

$$E = G, \quad F = 0;$$

such immersions always exist by the results* of Addendum 1. From equation (B) on pg. III.136 we have

$$(1) \quad K = k_1 k_2 = \frac{ln - m^2}{E^2}$$

$$(2) \quad H = \frac{1}{2}(k_1 + k_2) = \frac{l + n}{2E}.$$

A little calculation shows that the Codazzi-Mainardi equations (pg. III.56) become

$$\begin{aligned} l_y - m_x &= \frac{E_y}{2E}(l + n) = E_y H \\ m_y - n_x &= -\frac{E_x}{2E}(l + n) = -E_x H. \end{aligned}$$

But

$$EH = \frac{l + n}{2} \implies \begin{cases} E_y H = -E H_y + \frac{l_y}{2} + \frac{n_y}{2} \\ E_x H = -E H_x + \frac{l_x}{2} + \frac{n_x}{2}, \end{cases}$$

so the Codazzi-Mainardi equations can be written

$$(3) \quad \begin{aligned} \left(\frac{l - n}{2}\right)_x + m_y &= E H_x \\ \left(\frac{l - n}{2}\right)_y - m_x &= -E H_y. \end{aligned}$$

* At present we need Proposition 29 or 30, but we could make do with the much simpler Theorem 18, since it follows from (hard) theorems on partial differential equations that a surface of constant mean curvature must be analytic (see pg. V.147).

If we define the function $\Phi: U \rightarrow \mathbb{C}$ by

$$(4) \quad \Phi = \frac{l-n}{2} - i \cdot m,$$

then

$$\begin{aligned} |\Phi|^2 &= \frac{(l-n)^2}{4} + m^2 = \frac{(l+n)^2}{4} + m^2 - ln \\ &= E^2(H^2 - K) \quad \text{by (1) and (2)} \\ &= E^2(k_1 - k_2)^2/4. \end{aligned}$$

Thus the umbilics on $f(U)$ are the image of the zeros of Φ . Notice that if H is constant, so that $H_x = H_y = 0$, then equations (3) are precisely the Cauchy-Riemann equations for Φ ; thus Φ is complex analytic. So we immediately have

31. LEMMA. If M is a connected surface immersed in \mathbb{R}^3 with constant mean curvature, then either all points of M are umbilics, or else the umbilics are isolated.

PROOF. Since the analytic function Φ is identically zero if its zeros have an accumulation point, we see that for every $p \in M$ one of two possibilities must hold:

- (1) p has a neighborhood with no umbilics, except perhaps p ,
- (2) p has a neighborhood all of whose points are umbilics.

But the set of points p satisfying (1) is open, and so is the set of points p satisfying (2). Since M is connected, either (1) holds everywhere, or (2) holds everywhere. ♦

Now consider the lines of curvature on M , or rather their images in U under the map f^{-1} . Formula (D) on pg. III.136 says that a vector $\mathbf{v} = (a_1, a_2)$ is tangent to one of these curves if and only if

$$\begin{aligned} 0 &= \det \begin{pmatrix} a_2^2 & -a_1 a_2 & a_1^2 \\ E & 0 & E \\ l & m & n \end{pmatrix} \\ &= -E[-ma_1^2 + (l-n)a_1 a_2 + ma_2^2] \\ &\quad \{l, m, n \text{ evaluated at the point where } \mathbf{v} \\ &\quad \text{is considered to be a tangent vector}\}. \end{aligned}$$

Thus \mathbf{v} is tangent to $[f^{-1} \text{ of}]$ a line of curvature if and only if

$$-m\{dx(\mathbf{v})\}^2 + (l - n) dx(\mathbf{v}) dy(\mathbf{v}) + m\{dy(\mathbf{v})\}^2 = 0.$$

We can write the left side of this equation as the imaginary part of a complex number, namely

$$\begin{aligned} \operatorname{Im} \left[\frac{l - n}{2} - i \cdot m \right] \cdot [\{dx(\mathbf{v})\}^2 - \{dy(\mathbf{v})\}^2 + 2i dx(\mathbf{v}) dy(\mathbf{v})] \\ = \operatorname{Im} \Phi \cdot [\{dx(\mathbf{v})\}^2 - \{dy(\mathbf{v})\}^2 + 2i dx(\mathbf{v}) dy(\mathbf{v})]. \end{aligned}$$

Introducing the complex-valued 1-form dz , as on page 319, we can thus write our equation as

$$\operatorname{Im} \Phi \cdot \{dz(\mathbf{v})\}^2 = 0.$$

For any complex number $w \neq 0$, we let $\arg w$ be some angle between the x -axis and the ray from 0 through w , so that $w = |w|e^{i \arg w}$. Then the above equation holds if and only if there is an integer m with

$$\begin{aligned} m\pi &= \arg \Phi \cdot \{dz(\mathbf{v})\}^2 \\ &= \arg \Phi + 2 \arg dz(\mathbf{v}), \end{aligned}$$

or

$$(*) \quad \arg dz(\mathbf{v}) = -\frac{1}{2} \arg \Phi + \frac{m\pi}{2} \quad \text{for some integer } m.$$

In a neighborhood of an isolated umbilic of our surface M with constant H we consider the 1-dimensional distribution Δ formed by the multiples of the principle vectors with the larger principal curvature, say. The index of this distribution was defined in Addendum 2 to Chapter 4. We can now compute it in terms of Φ .

32. PROPOSITION. Let $f: U \rightarrow M$ be a conformal immersion into a surface M of constant mean curvature H , with corresponding analytic function Φ . Suppose that $p = f(0)$ is an isolated umbilic, so that $\Phi(0) = 0$, and consequently

$$\Phi(z) = a_n z^n + \cdots \quad a_n \neq 0, \quad n \geq 1.$$

Then the index of Δ at p is $-n/2$.

PROOF. We consider the distribution on U which is f^{-1} of Δ . Let $c: [0, 1] \rightarrow U$ be a small circle around 0. To compute the index of the distribution at 0, we must choose a continuous function $\theta: [0, 1] \rightarrow \mathbb{R}$ such that $\theta(t)$ is an angle between the x -axis and the direction of the distribution at $c(t)$; then the index is $[\theta(1) - \theta(0)]/2\pi$. First choose a continuous function $\phi: [0, 1] \rightarrow \mathbb{R}$ such that $\phi(t)$ is an argument for $\Phi(c(t))$. Then equation (*) shows that we must have

$$\theta(t) = -\frac{1}{2}\phi(t) + \frac{m\pi}{2},$$

where the integer m must be constant, by continuity. So the index in question is

$$\frac{1}{2\pi}[\pi(1) - \theta(0)] = -\frac{1}{2} \cdot \frac{1}{2\pi}[\phi(1) - \phi(0)].$$

But standard complex analysis results say that $\phi(1) - \phi(0) = 2\pi n$. [Here is a direct proof. Clearly $[\phi(1) - \phi(0)]/2\pi$ is just the degree of the map α from S^1 to $\mathbb{C} - \{0\}$ defined by

$$\begin{aligned} \alpha(t) &= \frac{1}{a_n} \Phi(c(t)) = c(t)^n [1 + \cdots] \\ &= c(t)^n [1 + d(t)], \end{aligned}$$

where we have

$$|d(t)| < 1 \quad \text{for a sufficiently small circle } c.$$

Now

$$|\alpha(t) - c(t)^n| = |c(t)^n d(t)| < |c(t)|^n.$$

So the line segment from $c(t)^n$ to $\alpha(t)$ does not contain 0. This means that α and $t \mapsto c(t)^n$ are homotopic as maps from S^1 to $\mathbb{C} - \{0\}$. So they have the same degree. But the degree of $t \mapsto c(t)^n$ is n .] ♦

All of this leads up to

33. THEOREM (H. HOPF). If M is an immersed sphere in \mathbb{R}^3 with constant mean curvature H , then M is a standard sphere.

PROOF. If all points of M were not umbilics, then by Lemma 31 there would be only finitely many umbilics. By Proposition 32, the index of Δ at each umbilic would be negative. This contradicts Theorem 4-20, since $\chi(M) = 2 > 0$. ♦

ADDENDUM 3

IMBEDDED SURFACES WITH
CONSTANT MEAN CURVATURE

In this Addendum we will prove that a compact *imbedded* surface $M \subset \mathbb{R}^3$ with constant mean curvature H_0 must be a standard sphere. Essentially the same proof works for imbedded hypersurfaces in \mathbb{R}^{n+1} , H^{n+1} , or an open hemisphere of S^{n+1} . The proof depends on a simple ingenious geometric construction, together with analytic results (Theorems 10-17 and 10-20) from Addendum 2 to Chapter 10; the proofs of these theorems can be read right now, for they do not depend on any material from Chapter 10 proper. These analytic results are applied to the present situation as follows.

Consider a surface given as the graph of a function $h: \mathbb{R}^2 \rightarrow \mathbb{R}$, and introduce the standard abbreviations

$$p = \frac{\partial h}{\partial x}, \quad q = \frac{\partial h}{\partial y}$$

$$r = \frac{\partial^2 h}{\partial x^2}, \quad s = \frac{\partial^2 h}{\partial x \partial y}, \quad t = \frac{\partial^2 h}{\partial y^2}.$$

For the condition that the surface has constant mean curvature H_0 we find, from (B') on pg. III.137, the equation

$$(*) \quad 0 = (1 + q^2)r - 2pq s + (1 + p^2)t - 2H_0(1 + p^2 + q^2)^{3/2}$$

$$= F(p, q, r, s, t).$$

Now let h_1 and h_2 be two solutions of (*), with corresponding partials p_1, \dots, t_1 and p_2, \dots, t_2 . If we denote the partial derivatives of F with respect to its 5 arguments as F_p, \dots, F_t , then at all points of \mathbb{R}^2 we have

$$0 = F(p_1, q_1, r_1, s_1, t_1) - F(p_2, q_2, r_2, s_2, t_2)$$

$$= \int_0^1 \frac{d}{d\tau} F(\tau p_1 + (1 - \tau)p_2, \dots, \tau t_1 + (1 - \tau)t_2) d\tau$$

$$= \int_0^1 (p_1 - p_2)F_p(\bullet) + \dots + (t_1 - t_2)F_t(\bullet) d\tau$$

where $\bullet = (\tau p_1 + (1 - \tau)p_2, \dots, \tau t_1 + (1 - \tau)t_2)$

$$= A \cdot (p_1 - p_2) + B \cdot (q_1 - q_2) + C \cdot (r_1 - r_2)$$

$$+ D \cdot (s_1 - s_2) + E \cdot (t_1 - t_2), \quad \text{say.}$$

Setting $u = h_1 - h_2$, and letting p, q, \dots, t now denote the partials of u , we see that u satisfies the equation

$$(**) \quad A \cdot p + B \cdot q + C \cdot r + D \cdot s + E \cdot t = 0.$$

34. LEMMA. Let h_1 and h_2 be two functions whose graphs are surfaces of the same constant mean curvature H_0 , both functions being defined either in a neighborhood of 0 in \mathbb{R}^2 , or in a neighborhood of 0 in the closed half-plane $\{(x, y) : y \geq 0\}$. Suppose that $h_1 \geq h_2$ in this domain, and that $h_1(0) = h_2(0)$. If h_1 and h_2 are defined only in the half-plane, assume also that $\partial h_1 / \partial x(0) = \partial h_2 / \partial x(0)$. Then $h_1 = h_2$ in a neighborhood of 0, or in a neighborhood of 0 in $\{(x, y) : y \geq 0\}$.

PROOF. Notice that for all $(\lambda, \mu) \neq (0, 0)$ we have

$$\begin{aligned} F_r \lambda^2 + F_s \lambda \mu + F_t \mu^2 &= (1 + q^2) \lambda^2 - 2pq \lambda \mu + (1 + p^2) \mu^2 \\ &= \lambda^2 + \mu^2 + (q\lambda - p\mu)^2 > 0, \end{aligned}$$

where F_r, F_s, F_t are evaluated at any point of \mathbb{R}^5 . So we also have

$$\begin{aligned} C \lambda^2 + D \lambda \mu + E \mu^2 &= \int_0^1 F_r(\bullet) \lambda^2 + F_s(\bullet) \lambda \mu + F_t(\bullet) \mu^2 d\tau \\ &> 0. \end{aligned}$$

Thus Theorems 10-17 and 10-20 apply to the solution $u = h_1 - h_2$ of equation (**). ♦

For the geometric part of the proof, we first note that the standard spheres are the only compact surfaces which have a plane of symmetry in every direction. In fact,

35. LEMMA. If $A \subset \mathbb{R}^3$ is bounded and has a plane of symmetry in every direction, then A is invariant under all rotations about some point $*$ (hence A is a union of concentric spheres around $*$).

PROOF. Choose 3 mutually orthogonal planes P_1, P_2, P_3 which are planes of symmetry for A , and let $*$ be the unique point in $P_1 \cap P_2 \cap P_3$. Let P be any other plane of symmetry. It is easy to see that if P does not go through $*$, then suitable compositions of the reflections through P_1, P_2, P_3 , and P will take any given point in A to points arbitrarily far from $*$. So if A is bounded, then we must have $*$ in P . Thus A is invariant under reflection through every plane through $*$. This implies that A is invariant under all rotations about $*$. ♦

It is this symmetry property of spheres which we will establish for any surface of constant mean curvature.

36. THEOREM (ALEXANDROV). Let M be a compact surface imbedded in \mathbb{R}^3 with constant mean curvature H_0 . Then M has a plane of symmetry in every direction, so M is a standard sphere.

PROOF. We know (Theorem I.11-14) that M is the boundary of some closed domain D . We can assume that our direction is the z -axis, and that M is placed so that it lies in the region where $z \geq 0$, and touches the plane $z = 0$. For each $a > 0$, let P_a be the plane $z = a$. The set of points of M which lie below P_a is a “hump” H_a . Let \tilde{H}_a be the reflection of H_a in P_a . For sufficiently small

$a > 0$, the set \tilde{H}_a will lie inside D . Consider the set of all $b > 0$ such that \tilde{H}_a lies in D for $0 \leq a \leq b$. This set clearly has a largest element c . There are then two possible cases, as illustrated below.

In the first case, there is a point $p \in \tilde{H}_c \cap M$ which is not on P_c . From the definition of c , it is easy to see that near p the surfaces M and \tilde{H}_c are the graphs of two functions h_1, h_2 with $h_1 \geq h_2$. Then Lemma 35 shows that M and \tilde{H}_c coincide in a neighborhood of p .

If there is no point $p \in \tilde{H}_c \cap M - P_c$, then we must have the situation shown in the second figure: for some point $p \in P_c$, the surface M has a vertical tangent plane at p . The part of M which lies above or on P_c is a surface-with-boundary, and near p it can be represented as a function h_1 on a closed

half-plane perpendicular to the (x, y) -plane. Similarly, \tilde{H}_c can be represented as a function h_2 on the same closed half-plane. This time we have $h_2 \geq h_1$. Lemma 35 shows that \tilde{H}_c coincides near p with the part of M which lies above or on P_c .

Now let \tilde{K} be the component of \tilde{H}_c which contains the point p (in either Case 1 or Case 2). This component \tilde{K} is the reflection in P_c of a component $K \subset H_c$. The argument of the above two paragraphs, together with a simple connectedness argument, shows that $\tilde{K} \subset M$. But $\tilde{K} \cup K \subset M$ is already a compact manifold. So we must have $\tilde{K} \cup K = M$. Thus M is symmetric with respect to the plane P_c . ♦

One of the most interesting aspects of this proof is the fact that constancy of the mean curvature was used in such a weak way. There are numerous other conditions which can be treated similarly; Alexandrov has a whole series of papers on this subject. A somewhat later paper by Alexandrov [2] generalizes Theorem 36 so as to allow many types of self-intersections of M . For example, if $M \subset \mathbb{R}^3$ is a compact surface, bounding a domain D , and $f: M \rightarrow \mathbb{R}^3$ is an immersion which can be extended to an immersion of D into \mathbb{R}^3 , then $f(M)$ does not have constant mean curvature unless it is a standard sphere. Naturally, the counterexamples of Wente, Abresch, and Kapouleas (page 311) cannot be of this sort.

ADDENDUM 4

THE SECOND VARIATION OF VOLUME

In this Addendum we will derive the formula for the second variation of volume, and give some applications. The calculation itself is a real bitch, and even the final formula is quite involved, so some preliminaries will be required.

1. For a submanifold $M \subset N$ and a vector $\xi \in M_p^\perp$ we have the map $A_\xi: M_p \rightarrow M_p$ with

$$\langle A_\xi(X), Y \rangle = \langle s(X, Y), \xi \rangle.$$

Since A_ξ is symmetric, it has n real eigenvalues $\lambda_1, \dots, \lambda_n$. We will let

$$\Sigma_2(\xi) = \sum_{i=1}^n \lambda_i^2 = \text{trace } A_\xi^2.$$

If ξ denotes, instead, a section of the normal bundle $\text{Nor } M$, then $\Sigma_2(\xi)$ is a function on M .

2. Given $\xi \in M_p^\perp$, we define the “partial Ricci tensor”

$$\text{Ric}_M(\xi) = - \sum_{i=1}^n \langle R'(\xi, X_i) X_i, \xi \rangle,$$

where X_1, \dots, X_n is an orthonormal basis of M_p ; it is easily seen that this does not depend on the choice of X_1, \dots, X_n . Naturally, $\text{Ric}_M(\xi)$ denotes a function on M if ξ denotes a section of the normal bundle $\text{Nor } M$.

3. Recall from Addendum 1 of Chapter 7 that if W is a vector field tangent along the manifold M , then $\text{div } W$ is the function on M defined by

$$(\text{div } W)(p) = \text{trace}(X_p \mapsto \nabla_{X_p} W) = \sum_{i=1}^n \langle \nabla_{X_i} W, X_i \rangle,$$

where X_1, \dots, X_n is any orthonormal basis of M_p .

4. We also recall from this same Addendum that we have defined the Laplacian $\Delta\psi$ for a section ψ of a vector bundle over a Riemannian manifold M ; to define this we needed a connection on the bundle. For a submanifold $M \subset N$ of a Riemannian manifold N , we have the induced metric on M , and a connection D on the normal bundle defined by

$$D_X \psi = \perp \nabla'_X \psi, \quad \nabla' = \text{the covariant derivative in } N.$$

Thus if ψ is a section of the normal bundle, we have

$$\Delta\psi(p) = \sum_{j=1}^n \perp \nabla'_{X_j(p)} (\perp \nabla'_{X_j} \psi),$$

where X_1, \dots, X_n is an orthonormal moving frame with

$$\nabla_{X_i} X_j(p) = 0, \quad \nabla = \text{covariant derivative in } M.$$

5. We will require the following properties of contractions $X \lrcorner \omega$ and Lie derivatives $L_Z \omega$:

- | | | |
|-----|---|--|
| (a) | $Z \lrcorner (\phi \wedge \eta) = (Z \lrcorner \phi) \wedge \eta + (-1)^k \phi \wedge (Z \lrcorner \eta)$ | for ϕ a k -form
[Problem I.7-4] |
| (b) | $L_Z(\phi \wedge \eta) = L_Z \phi \wedge \eta + \phi \wedge L_Z \eta$ | } [Problem I.7-18] |
| (c) | $L_Z \omega = Z \lrcorner d\omega + d(Z \lrcorner \omega)$ | |
| (d) | $L_Z d\omega = dL_Z \omega$ | |
| (e) | $L_{Y+Z} \omega = L_Y \omega + L_Z \omega$ | [Problem I.5-14] |
| (f) | $L_Z(Y \lrcorner \omega) = [Z, Y] \lrcorner \omega + Y \lrcorner L_Z \omega$ | [an exercise, using
Problem I.7-18(c)]. |

6. Finally, there is one important way that the second variation formula for volume will differ from the second variation formula for energy. If $\alpha: (-\varepsilon, \varepsilon) \times M \rightarrow N$ is a variation of $\bar{\alpha}(0) = f: M \rightarrow N$, and $W(p) = \partial\alpha/\partial u(0, p)$ is the variation vector field, then our formula will involve not merely W , but also $\tilde{W} = \partial\alpha/\partial u$. We will define vector fields $\mathsf{T}\tilde{W}$ and $\perp\tilde{W}$ along α by writing $\tilde{W}(u, p) = \mathsf{T}\tilde{W}(u, p) + \perp\tilde{W}(u, p)$, where $\mathsf{T}\tilde{W}(u, p)$ is tangent to $\bar{\alpha}(u)(M)$ at $u(p)$ and $\perp\tilde{W}(u, p)$ is orthogonal to $\bar{\alpha}(u)(M)$ at $u(p)$.

37. THEOREM. Let $f: M \rightarrow N$ be a minimal immersion of an oriented n -dimensional manifold (-with-boundary) M into a Riemannian manifold $(N^m, \langle \cdot, \cdot \rangle)$, and let $\alpha: (-\varepsilon, \varepsilon) \times M \rightarrow N$ be a variation of f through immersions. Let W be the variation vector field, and let $\tilde{W} = \partial\alpha/\partial u$. If $\Gamma(u)$ is the volume form on M determined by the metric $\bar{\alpha}(u)^*\langle \cdot, \cdot \rangle$ and the given orientation of M , then

$$\begin{aligned} \ddot{\Gamma}(0) = & [\text{Ric}_M(\perp W) - \Sigma_2(\perp W) - \langle \perp W, \Delta(\perp W) \rangle] \cdot \Gamma(0) \\ & + d(\text{div } \mathsf{T}W \cdot (\mathsf{T}W \lrcorner \Gamma(0)) + \mathsf{T}[\perp\tilde{W}, \mathsf{T}\tilde{W}] \lrcorner \Gamma(0)). \end{aligned}$$

PROOF. We will regard this proof as a continuation of the proof of Theorem 11; we will refer to equations (1)–(10) in that proof, and therefore commence our numbering of equations with (11). Once again we first consider a point $p_0 \in M$ where $W(p_0)$ is not tangent to $f(M)$. We choose V as before, and assume that f is just the inclusion $i: V \rightarrow N$. We will use all the notation introduced in the proof of Theorem 11, and we will also introduce the abbreviations

$$(11) \quad \theta^j = i^* \phi^j \quad 1 \leq j \leq n.$$

Since our immersion is minimal ($\eta = 0$), equation (9) shows that

$$(12) \quad i^*\{Z \lrcorner d\Phi\} = 0 \quad \text{for all vector fields } Z \text{ along } V.$$

Using (6), we can write $d\Phi$ as

$$(13) \quad d\Phi = \sum_{r=n+1}^m \phi^r \wedge \mu_r, \quad \text{for } \mu_r = \sum_{j=1}^n \phi^1 \wedge \cdots \wedge \psi_r^j \wedge \cdots \wedge \phi^n.$$

Then (12) becomes

$$\sum_{r=n+1}^m \theta^r(Z) i^* \mu_r = 0, \quad \text{using (a) on page 356 and } i^* \phi^r = 0.$$

Since this is true for arbitrary Z , we have

$$(14) \quad i^* \mu_r = 0, \quad \text{and hence} \quad \sum_{j=1}^n \psi_r^j(X_j) = 0 \quad \text{along } V.$$

Now let us apply equation (5) to all u , not just $u = 0$. We obtain

$$\dot{\Gamma}(u) = \bar{\alpha}(u)^*(\tilde{W} \lrcorner d\Phi) + \bar{\alpha}(u)^*d(\tilde{W} \lrcorner \Phi).$$

As before, this implies that

$$(15) \quad \begin{aligned} \ddot{\Gamma}(0) &= i^*\{L_{\tilde{W}}(\tilde{W} \lrcorner d\Phi)\} + i^*\{L_{\tilde{W}}d(\tilde{W} \lrcorner \Phi)\} \\ &= i^*\{L_{\tilde{W}}(\tilde{W} \lrcorner d\Phi)\} + d(i^*\{L_{\tilde{W}}(\tilde{W} \lrcorner \Phi)\}) \quad \text{by (d).} \end{aligned}$$

Once again we will show that the two terms on the right are precisely the terms appearing in the statement of the theorem.

The first term is the one that will give us all the difficulties, and we will use some preliminary tricks to make the calculations manageable. First of all, we

want to be more particular in our choice of the moving frame $X_1, \dots, X_n, X_{n+1}, \dots, X_m$. We will assume that $X_1(p_0), \dots, X_n(p_0)$ is a basis of eigenvectors for $A_{\perp W(p_0)}$, with corresponding eigenvalues $\lambda_1, \dots, \lambda_n$. This means that

$$\begin{aligned}
 \lambda_j \delta_{jk} &= \langle A_{\perp W(p_0)} X_j(p_0), X_k(p_0) \rangle \\
 &= \langle s(X_k(p_0), X_j(p_0)), \perp W(p_0) \rangle \\
 &= \langle \perp \nabla'_{X_k} X_j, \perp W \rangle && \text{at } p_0 \\
 &= \left\langle \sum_{r=n+1}^m \psi_j^r(X_k) X_r, \perp W \right\rangle && \text{at } p_0 \\
 &= - \sum_{r=n+1}^m \phi^r(W) \cdot \psi_r^j(X_k) && \text{at } p_0,
 \end{aligned}$$

and consequently,

$$(16) \quad \sum_{r=n+1}^m \phi^r(W) i^* \psi_r^j = -\lambda_j \theta^j \quad \text{at } p_0.$$

We still have considerable leeway in the choice of our moving frame X_1, \dots, X_m . We can replace it with a new moving frame $\bar{X}_1, \dots, \bar{X}_m$ defined by

$$\bar{X}_\alpha = \sum_{\beta=1}^m M_\alpha^\beta X_\beta,$$

where (M_α^β) is a matrix of functions such that

- (i) (M_α^β) is always orthogonal, $(M_\alpha^\beta)^{-1} = (M_\beta^\alpha)$,
- (ii) $M_r^j = M_j^r = 0 \quad 1 \leq j \leq n, \quad n+1 \leq r \leq m$,
- (iii) $(M_\alpha^\beta(p_0)) = I$.

Condition (i) means that the new moving frame is orthonormal, and condition (ii) implies that (1) and (2) still hold, so that the \bar{X}_j are tangent to the $\bar{\alpha}(u)(V)$, while the \bar{X}_r are orthogonal. Condition (iii) means that the frame is not changed at p_0 , so that equation (16) still holds. The dual 1-forms $\bar{\phi}^\alpha$ are related to the ϕ^β by

$$\bar{\phi}^\alpha = \sum_{\beta=1}^m M_\alpha^\beta \phi^\beta. \quad \bar{\phi}^\alpha(p_0) = \phi^\alpha(p_0).$$

so the corresponding connection forms $\bar{\psi}_\beta^\alpha$ satisfy

$$\begin{aligned}
 -\sum_{\beta=1}^m \bar{\psi}_\beta^\alpha \wedge \bar{\phi}^\beta &= d\bar{\phi}^\alpha = \sum_{\beta=1}^m dM_\alpha^\beta \wedge \phi^\beta + \sum_{\beta=1}^m M_\alpha^\beta \wedge d\phi^\beta \\
 &= \sum_{\beta=1}^m dM_\alpha^\beta \wedge \phi^\beta - \sum_{\beta,\gamma=1}^m M_\alpha^\beta \psi_\gamma^\beta \wedge \phi^\gamma \\
 &= \sum_{\beta=1}^m \sum_{\delta=1}^m M_\beta^\delta dM_\alpha^\beta \wedge \bar{\phi}^\delta - \sum_{\beta,\gamma,\delta=1}^m M_\alpha^\beta M_\delta^\gamma \psi_\gamma^\beta \wedge \bar{\phi}^\delta \\
 &= -\sum_{\beta=1}^m \left[\sum_{\gamma,\delta=1}^m M_\alpha^\delta M_\beta^\gamma \psi_\gamma^\delta - \sum_{\delta=1}^m M_\delta^\beta dM_\alpha^\delta \right] \wedge \bar{\phi}^\beta.
 \end{aligned}$$

Now $\sum_{\gamma,\delta} M_\alpha^\delta M_\beta^\gamma \psi_\gamma^\delta$ is easily seen to be skew-symmetric with respect to α and β , since $\psi_\gamma^\delta = -\psi_\delta^\gamma$. Since (M_α^β) is orthogonal and $M(p_0) = I$, we also have skew-symmetry for $\sum_{\delta} M_\delta^\beta dM_\alpha^\delta$ at p_0 . So Proposition II.7-4 (which is really a result about forms on a single vector space) shows that at p_0 we have

$$(iv) \quad \bar{\psi}_\beta^\alpha(p_0) = \psi_\beta^\alpha(p_0) - dM_\alpha^\beta(p_0).$$

Now we claim that it is possible to choose M_α^β so that

$$(v) \quad \begin{cases} dM_k^j(p_0) = \psi_k^j(p_0) & 1 \leq j, k \leq n \\ dM_s^r(p_0) = \psi_s^r(p_0) & n+1 \leq r, s \leq m. \end{cases}$$

In fact, for every unit tangent vector X at p_0 we can define

$$\begin{aligned}
 M_k^j(\exp tX) &= \exp(t\psi_k^j(X)) & 1 \leq j, k \leq n \\
 M_s^r(\exp tX) &= \exp(t\psi_s^r(X)) & n+1 \leq r, s \leq m \\
 M_r^j &= M_j^r = 0,
 \end{aligned}$$

where the exp on the right is the ordinary exponential of matrices. Then the matrices (M_β^α) satisfy (v); they also satisfy (i)–(iii), the matrices (M_k^j) and (M_s^r) being orthogonal since they are exp of skew-symmetric matrices. In connection with (iv), we thus see that our moving frame can be picked so that it satisfies not only (16), but also

$$(17) \quad \begin{cases} \psi_k^j(p_0) = 0 & 1 \leq j, k \leq n \\ \psi_s^r(p_0) = 0 & n+1 \leq r, s \leq m. \end{cases}$$

In addition to this special choice of the moving frame, we require another preliminary move. We are trying to show that $i^*\{L_{\tilde{W}}(\tilde{W} \lrcorner d\Phi)\}$ is the first term in the formula of the theorem. We notice that this term involves only the perpendicular component $\perp W$ of W . We can ease the strain of the calculations by first proving that the same is true of the expression that we have to work with. In the following lemma, $\top \tilde{W}$ and $\perp \tilde{W}$ actually denote extensions of these vector fields to a neighborhood of image α .

38. LEMMA. For a minimal immersion we have

$$i^*\{L_{\tilde{W}}(\tilde{W} \lrcorner d\Phi)\} = i^*\{L_{\perp \tilde{W}}(\perp \tilde{W} \lrcorner d\Phi)\}.$$

PROOF. By property (c), which we stated before the theorem, we have

$$i^*\{L_{\tilde{W}}(\tilde{W} \lrcorner d\Phi)\} = i^*\{\tilde{W} \lrcorner d(\tilde{W} \lrcorner d\Phi)\}.$$

For vector fields Y and Z in N , define

$$\mathcal{J}(Y, Z) = i^*\{Y \lrcorner d(Z \lrcorner d\Phi)\},$$

so that

$$i^*\{L_{\tilde{W}}(\tilde{W} \lrcorner d\Phi)\} = \mathcal{J}(\tilde{W}, \tilde{W}).$$

It is clear that \mathcal{J} is bilinear over \mathbb{R} . We will show that $\mathcal{J}(Y, Z) = 0$ if either Y or Z is tangent along M . The lemma then follows by writing $\tilde{W} = \top \tilde{W} + \perp \tilde{W}$.

Suppose first that Y is tangent along M . Then

$$\begin{aligned} \mathcal{J}(Y, Z) &= i^*\{Y \lrcorner d(Z \lrcorner d\Phi)\} \\ &= i^*\{L_Y(Z \lrcorner d\Phi) - d(Y \lrcorner Z \lrcorner d\Phi)\} \quad \text{by (c).} \end{aligned}$$

Now equation (12) tells us that $Z \lrcorner d\Phi$ gives 0 when applied to tangent vectors of M . The same is clearly true for $Y \lrcorner Z \lrcorner d\Phi$, since Y is itself tangent along M . So

$$i^*\{Y \lrcorner Z \lrcorner d\Phi\} = 0, \quad \text{and hence} \quad i^*\{d(Y \lrcorner Z \lrcorner d\Phi)\} = 0.$$

On the other hand, since Y is tangent to M we clearly also have

$$i^*\{L_Y(Z \lrcorner d\Phi)\} = 0.$$

Thus $\mathcal{J}(Y, Z) = 0$.

Now suppose that Z is tangent along M . We have

$$\begin{aligned}
 \mathcal{L}(Y, Z) &= i^*\{Y \lrcorner d(Z \lrcorner d\Phi)\} \\
 &= i^*\{Y \lrcorner L_Z d\Phi\} && \text{by (c)} \\
 &= i^*\{[Y, Z] \lrcorner d\Phi\} + i^*\{L_Z(Y \lrcorner d\Phi)\} && \text{by (f)} \\
 &= i^*\{[Y, Z] \lrcorner d\Phi\} \\
 &\quad + i^*\{Z \lrcorner d(Y \lrcorner d\Phi)\} + i^*\{d(Z \lrcorner Y \lrcorner d\Phi)\} && \text{by (c)} \\
 &= i^*\{[Y, Z] \lrcorner d\Phi\} + \mathcal{L}(Z, Y) + i^*\{d(Z \lrcorner Y \lrcorner d\Phi)\}.
 \end{aligned}$$

The first term is 0 by (12). The second term is 0 by what we have already proved. The third term is 0 for the same reason that $i^*\{d(Y \lrcorner Z \lrcorner d\Phi)\}$ was 0 before. **Q.E.D.**

We are now finally ready to carry out the computation.

Step 1. We claim that

$$(18) \quad i^*\{L_{\widetilde{W}}\phi^r\} = 0 = i^*\{L_{\perp\widetilde{W}}\phi^r\}, \quad n+1 \leq r \leq m.$$

To see this, choose Y to be a vector field tangent to V and let $i_*Y = X$. Then

$$\begin{aligned}
 i^*\{L_{\widetilde{W}}\phi^r\}(Y) &= L_{\widetilde{W}}\phi^r(X) \\
 &= d(W \lrcorner \phi^r)(X) + (W \lrcorner d\phi^r)(X) && \text{by (c)} \\
 &= X(\phi^r(W)) + d\phi^r(W, X) \\
 &= X(\phi^r(W)) \\
 &\quad + [W(\phi^r(X)) - X(\phi^r(W)) - \phi^r([W, X])] && \text{by pg. I.215} \\
 &= -\phi^r([W, X]).
 \end{aligned}$$

But if t^1, \dots, t^n is a coordinate system around p_0 in V , then X is a linear combination of $\partial\alpha/\partial t^1, \dots, \partial\alpha/\partial t^n$,

$$X = \sum_{j=1}^n a_j \frac{\partial\alpha}{\partial t^j}.$$

We have

$$\left[W, \frac{\partial\alpha}{\partial t^j}\right] = \left[\frac{\partial\alpha}{\partial u}, \frac{\partial\alpha}{\partial t^j}\right] = \alpha_* \left(\left[\frac{\partial}{\partial u}, \frac{\partial}{\partial t^j}\right]\right) = 0,$$

so

$$[W, X] = \left[W, \sum_{j=1}^n a_j \frac{\partial\alpha}{\partial t^j}\right] = - \sum_{j=1}^n W(a_j) \frac{\partial\alpha}{\partial t^j} \quad \text{by pg. I.156.}$$

Thus $[W, X]$ is also tangent to V , so $\phi^r([W, X]) = 0$. This shows that $i^*\{L_{\tilde{W}}\phi^r\} = 0$.

We also have

$$i^*\{L_{\top\tilde{W}}\phi^r\} = -\phi^r([\top W, X]) = 0,$$

since $[\top W, X]$ is tangent to V . Hence $i^*\{L_{\perp\tilde{W}}\phi^r\} = 0$ also.

Step 2. For $1 \leq j \leq n$, we have

$$\begin{aligned} i^*\{L_{\tilde{W}}\phi^j\} &= i^*\{d(\tilde{W} \lrcorner \phi^j)\} + i^*\{\tilde{W} \lrcorner d\phi^j\} && \text{by (c)} \\ &= d(\phi^j(W)) - i^*\left\{\tilde{W} \lrcorner \sum_{\alpha=1}^m \psi_{\alpha}^j \wedge \phi^{\alpha}\right\} \\ &= d(\phi^j(W)) - \sum_{k=1}^m \psi_k^j(W)\theta^k + \sum_{\alpha=1}^m \phi^{\alpha}(W)i^*\psi_{\alpha}^j && \text{by (a)}. \end{aligned}$$

Using (16) and (17) we see that

$$(19) \quad i^*\{L_{\tilde{W}}\phi^j\} = d(\phi^j(W)) - \lambda_j\theta^j \quad \text{at } p_0.$$

Similarly, we find that

$$(20) \quad i^*\{L_{\perp\tilde{W}}\phi^j\} = -\lambda_j\theta^j \quad \text{at } p_0.$$

Step 3. Using the second structural equation to express $d\psi_r^j$ in terms of the curvature forms Ψ_r^j , we have

$$\begin{aligned} i^*\{L_{\perp\tilde{W}}\psi_r^j\} &= i^*\{\perp\tilde{W} \lrcorner d\psi_r^j\} + i^*\{d(\perp\tilde{W} \lrcorner \psi_r^j)\} && \text{by (c)} \\ &= -i^*\left\{\perp\tilde{W} \lrcorner \sum_{\gamma=1}^m \psi_{\gamma}^j \wedge \psi_r^{\gamma}\right\} + i^*\{\perp\tilde{W} \lrcorner \Psi_r^j\} + d(\psi_r^j(\perp W)). \end{aligned}$$

Because of equation (17), each term $\psi_{\gamma}^j \wedge \psi_r^{\gamma}$ always has one factor equal to 0 at p_0 , so we obtain

$$(21) \quad i^*\{L_{\perp\tilde{W}}\psi_r^j\} = i^*\{\perp\tilde{W} \lrcorner \Psi_r^j\} + d(\psi_r^j(\perp W)) \quad \text{at } p_0.$$

Step 4. Referring to (13) for the definition of μ_r , we now compute

$$\begin{aligned} i^*\{L_{\perp\tilde{W}}\mu_r\} &= i^*\left\{L_{\perp\tilde{W}} \sum_{j=1}^n \phi^1 \wedge \cdots \wedge \psi_r^j \wedge \cdots \wedge \phi^n\right\} \\ &= \sum_{j=1}^n \theta^1 \wedge \cdots \wedge i^*\{L_{\perp\tilde{W}}\psi_r^j\} \wedge \cdots \wedge \theta^n \\ &\quad + \sum_{j=1}^n \left[\sum_{k \neq j} \theta^1 \wedge \cdots \wedge i^*\{L_{\perp\tilde{W}}\phi^k\} \wedge \cdots \wedge i^*\psi_r^j \wedge \cdots \wedge \theta^n \right]. \end{aligned}$$

Substituting from (20) and (21), and rearranging slightly, we have

$$\begin{aligned} i^*\{L_{\perp\tilde{W}}\mu_r\} &= \sum_{j=1}^n \theta^1 \wedge \cdots \wedge i^*\{\perp\tilde{W} \lrcorner \Psi_r^j\} \wedge \cdots \wedge \theta^n \\ &\quad + \sum_{j=1}^n \left[\sum_{k \neq j} \theta^1 \wedge \cdots \wedge -\lambda_k \theta^k \wedge \cdots \wedge i^*\psi_r^j \wedge \cdots \wedge \theta^n \right] \\ &\quad + \sum_{j=1}^n \theta^1 \wedge \cdots \wedge d(\psi_r^j(\perp W)) \wedge \cdots \wedge \theta^n \quad \text{at } p_0. \end{aligned}$$

Notice that

$$\begin{aligned} \sum_{j=1}^n \left[\sum_{k \neq j} \theta^1 \wedge \cdots \wedge -\lambda_k \theta^k \wedge \cdots \wedge i^*\psi_r^j \wedge \cdots \wedge \theta^n \right] \\ = \sum_{j=1}^n \left(\sum_{k \neq j} -\lambda_k \right) \theta^1 \wedge \cdots \wedge i^*\psi_r^j \wedge \cdots \wedge \theta^n. \end{aligned}$$

But $\sum_{k=1}^n \lambda_k = 0$, since our immersion is minimal; so $\sum_{k \neq j} -\lambda_k = \lambda_j$. Thus

$$\begin{aligned} (22) \quad i^*\{L_{\perp\tilde{W}}\mu_r\} &= \sum_{j=1}^n \theta^1 \wedge \cdots \wedge i^*\{\perp\tilde{W} \lrcorner \Psi_r^j\} \wedge \cdots \wedge \theta^n \\ &\quad + \sum_{j=1}^n \lambda_j \theta^1 \wedge \cdots \wedge i^*\psi_r^j \wedge \cdots \wedge \theta^n \\ &\quad + \sum_{j=1}^n \theta^1 \wedge \cdots \wedge d(\psi_r^j(\perp W)) \wedge \cdots \wedge \theta^n \quad \text{at } p_0. \end{aligned}$$

Step 5. We have

$$\begin{aligned} i^*\{L_{\tilde{W}}(\tilde{W} \lrcorner d\Phi)\} &= i^*\{L_{\perp\tilde{W}}(\perp\tilde{W} \lrcorner d\Phi)\} && \text{by Lemma 38} \\ &= i^*\{\perp\tilde{W} \lrcorner d(\perp\tilde{W} \lrcorner d\Phi)\} && \text{by (c)} \\ &= i^*\{\perp\tilde{W} \lrcorner L_{\perp\tilde{W}}d\Phi\} && \text{by (c) again} \\ &= \sum_{r=n+1}^m i^*\{\perp\tilde{W} \lrcorner L_{\perp\tilde{W}}(\phi^r \wedge \mu_r)\} && \text{by (13)} \\ &= \sum_{r=n+1}^m i^*\{\perp\tilde{W} \lrcorner (L_{\perp\tilde{W}}\phi^r \wedge \mu_r)\} \\ &\quad + \sum_{r=n+1}^m i^*\{\perp\tilde{W} \lrcorner (\phi^r \wedge L_{\perp\tilde{W}}\mu_r)\} && \text{by (b).} \end{aligned}$$

When we expand the first of these sums by (a), we obtain two terms, one involving $i^*\mu_r$ and one involving $i^*\{L_{\perp\tilde{W}}\phi^r\}$. These will both be 0, by (14) and (18), so we obtain

$$\begin{aligned} i^*\{L_{\tilde{W}}(\tilde{W} \lrcorner d\Phi)\} &= \sum_{r=n+1}^m i^*\{\perp\tilde{W} \lrcorner (\phi^r \wedge L_{\perp\tilde{W}}\mu_r)\} \\ &= \sum_{r=n+1}^m \phi^r(W) i^*\{L_{\perp\tilde{W}}\mu_r\} \quad \text{by (a).} \end{aligned}$$

Substituting in from (22), we obtain

$$\begin{aligned} (23) \quad i^*\{L_{\tilde{W}}(\tilde{W} \lrcorner d\Phi)\} &= \sum_{r=n+1}^m \phi^r(W) \sum_{j=1}^n \theta^1 \wedge \cdots \wedge i^*\{\perp\tilde{W} \lrcorner \Psi_r^j\} \wedge \cdots \wedge \theta^n \\ &\quad + \sum_{r=n+1}^m \phi^r(W) \sum_{j=1}^n \lambda_j \theta^1 \wedge \cdots \wedge i^*\psi_r^j \wedge \cdots \wedge \theta^n \\ &\quad + \sum_{r=n+1}^m \phi^r(W) \sum_{j=1}^n \theta^1 \wedge \cdots \wedge d(\psi_r^j(\perp W)) \wedge \cdots \wedge \theta^n \quad \text{at } p_0 \\ &= S_1 + S_2 + S_3, \quad \text{say.} \end{aligned}$$

Step 6. We will see what each of these sums gives when applied to the n -tuple of vectors $X_1(p_0), \dots, X_n(p_0)$.

Recall that

$$\Psi_r^j(X_\alpha, X_\beta) = \langle R'(X_\alpha, X_\beta)X_r, X_j \rangle.$$

Thus we have

$$\begin{aligned} S_1(X_1, \dots, X_n) &= \sum_{r=n+1}^m \phi^r(W) \sum_{j=1}^n \Psi_r^j(\perp W, X_j) && \text{at } p_0 \\ &= \sum_{r=n+1}^m \phi^r(W) \sum_{j=1}^n \langle R'(\perp W, X_j)X_r, X_j \rangle && \text{at } p_0 \\ &= - \sum_{r=n+1}^m \phi^r(W) \langle R'(\perp W, X_j)X_j, X_r \rangle && \text{at } p_0 \\ &= -\langle R'(\perp W, X_j)X_j, \perp W \rangle = \text{Ric}_M(\perp W) && \text{at } p_0. \end{aligned}$$

Hence

$$(24) \quad S_1 = \text{Ric}_M(\perp W) \cdot \Gamma(0) \quad \text{at } p_0.$$

Next we have

$$\begin{aligned} S_2(X_1, \dots, X_n) &= \sum_{r=n+1}^m \phi^r(W) \sum_{j=1}^n \lambda_j \psi_r^j(X_j) \quad \text{at } p_0 \\ &= \sum_{j=1}^n \lambda_j \sum_{r=n+1}^m \phi^r(W) \psi_r^j(X_j) \quad \text{at } p_0 \\ &= - \sum_{j=1}^n \lambda_j^2 \quad \text{by (16).} \end{aligned}$$

Hence

$$(25) \quad S_2 = -\Sigma_2(\perp W) \cdot \Gamma(0) \quad \text{at } p_0.$$

To evaluate S_3 , we note that $d(\psi_r^j(\perp W)) = \sum_i d(\psi_r^j(\perp W))(X_i) \cdot \theta^i$. So we obtain

$$\begin{aligned} (26) \quad S_3(X_1, \dots, X_n) &= \sum_{r=n+1}^m \phi^r(W) \sum_{j=1}^n d(\psi_r^j(\perp W))(X_j) \quad \text{at } p_0 \\ &= \sum_{j=1}^n \sum_{r=n+1}^m \phi^r(W) X_j(\psi_r^j(\perp W)) \quad \text{at } p_0. \end{aligned}$$

Step 7. The coefficient of $\Gamma(0)$ in the statement of the theorem will clearly be completely accounted for as soon as we show that

$$(27) \quad S_3(X_1, \dots, X_n) = -\langle \perp W, \Delta(\perp W) \rangle \quad \text{at } p_0.$$

Equation (17) implies that $\langle \nabla'_{X_i} X_k, X_j \rangle = 0$ at p_0 , and hence that $\nabla_{X_i} X_k = 0$ at p_0 , where ∇ is the covariant derivative in V . So

$$\Delta(\perp W) = \sum_{j=1}^n \perp \nabla'_{X_j} (\perp \nabla'_{X_j} \perp W).$$

Now

$$\begin{aligned}
 \nabla'_{X_j} \perp W &= \nabla'_{X_j} \left(\sum_{r=n+1}^m \phi^r(W) X_r \right) \\
 &= \sum_{r=n+1}^m X_j(\phi^r(W)) X_r + \sum_{r=n+1}^m \phi^r(W) \nabla'_{X_j} X_r \\
 &= \sum_{r=n+1}^m X_j(\phi^r(W)) X_r + \sum_{r=n+1}^m \phi^r(W) \sum_{\alpha=1}^m \psi_r^\alpha(X_j) X_\alpha,
 \end{aligned}$$

so

$$\perp(\nabla'_{X_j} \perp W) = \sum_{r=n+1}^m [X_j(\phi^r(W)) + \sum_{s=n+1}^m \phi^s(W) \psi_s^r(X_j)] X_r.$$

Hence

$$\begin{aligned}
 \nabla'_{X_j} (\perp \nabla'_{X_j} \perp W) &= \sum_{r=n+1}^m X_j \left(X_j(\phi^r(W)) + \sum_{s=n+1}^m \phi^s(W) \psi_s^r(X_j) \right) \cdot X_r \\
 &\quad + \sum_{r=n+1}^m [X_j(\phi^r(W)) + \sum_{s=n+1}^m \phi^s(W) \psi_s^r(X_j)] \cdot \sum_{\alpha=1}^m \psi_r^\alpha(X_j) X_\alpha.
 \end{aligned}$$

Using (17), we obtain*

$$\perp \nabla'_{X_j} (\perp \nabla'_{X_j} \perp W) = \sum_{r=n+1}^m [X_j(X_j(\phi^r(W))) + \sum_{s=n+1}^m \phi^s(W) X_j(\psi_s^r(X_j))] X_r \text{ at } p_0,$$

and therefore

$$\begin{aligned}
 (28) \quad \langle \perp W, \Delta(\perp W) \rangle &= \sum_{j=1}^n \sum_{r=n+1}^m \phi^r(W) \cdot [X_j(X_j(\phi^r(W))) \\
 &\quad + \sum_{s=n+1}^m \phi^s(W) X_j(\psi_s^r(X_j))] \quad \text{at } p_0 \\
 &= \sum_{j=1}^n \sum_{r=n+1}^m \phi^r(W) X_j(X_j(\phi^r(W))) \quad \text{at } p_0.
 \end{aligned}$$

since $\psi_s^r = -\psi_r^s$.

*Note that $X_j(\psi_s^r(X_j))$ need not be zero at p_0 , even though $\psi_s^r(X_j) = 0$ at p_0 .

We can find out something about the $X_j(\phi^r(W))$ by writing (18) in the form

$$\begin{aligned}
 0 &= i^*\{L_{\perp \tilde{W}} \phi^r\} = i^*\{d(\perp \tilde{W} \lrcorner \phi^r)\} + i^*\{\perp \tilde{W} \lrcorner d\phi^r\} && \text{by (c)} \\
 &= d(\phi^r(W)) - i^*\left\{\perp \tilde{W} \lrcorner \sum_{\alpha=1}^m \psi_\alpha^r \wedge \phi^\alpha\right\} \\
 &= d(\phi^r(W)) - \sum_{k=1}^n \psi_k^r(\perp W) \theta^k + \sum_{s=n+1}^m \phi^s(W) i^* \psi_s^r && \text{by (a).}
 \end{aligned}$$

This gives us

$$X_j(\phi^r(W)) = -\psi_r^j(\perp W) - \sum_{s=n+1}^m \phi^s(W) \psi_s^r(X_j);$$

using (17) we obtain

$$X_j(X_j(\phi^r(W))) = -X_j(\psi_r^j(\perp W)) - \sum_{s=n+1}^m \phi^s(W) X_j(\psi_s^r(X_j)) \quad \text{at } p_0.$$

Substituting into (28), we get

$$\begin{aligned}
 \langle \perp W, \Delta(\perp W) \rangle &= - \sum_{j=1}^n \sum_{r=n+1}^m \phi^r(W) X_j(\psi_r^j(\perp W)) \\
 &\quad - \sum_{j=1}^n \sum_{r,s=n+1}^m \phi^r(W) \phi^s(W) X_j(\psi_s^r(X_j)) \\
 &= - \sum_{j=1}^n \sum_{r=n+1}^m \phi^r(W) X_j(\psi_r^j(\perp W)) \quad \text{at } p_0, \text{ since } \psi_s^r = -\psi_r^s.
 \end{aligned}$$

This proves (27), and completes our calculation of the first term in (15).

The second term in (15) will not be nearly so bad. We have

$$\begin{aligned}
 (29) \quad i^*\{L_{\tilde{W}}(\tilde{W} \lrcorner \Phi)\} &= i^*\{\tilde{W} \lrcorner d(\tilde{W} \lrcorner \Phi)\} && \text{by (c)} \\
 &= i^*\{\tilde{W} \lrcorner L_{\tilde{W}} \Phi\} && \text{by (c)} \\
 &= i^*\left\{\tilde{W} \lrcorner \sum_{j=1}^n \phi^1 \wedge \cdots \wedge L_{\tilde{W}} \phi^j \wedge \cdots \wedge \phi^n\right\} && \text{by (b).}
 \end{aligned}$$

To show that

$$(30) \quad i^*\{L_{\tilde{W}}(\tilde{W} \lrcorner \Phi)\} = \operatorname{div} \mathbf{T}W \cdot (\mathbf{T}W \lrcorner \Gamma(0)) + \mathbf{T}[\perp \tilde{W}, \mathbf{T}\tilde{W}] \lrcorner \Gamma(0),$$

it obviously suffices to show that both sides give the same result when applied to any $(n-1)$ -tuple $(X_1, \dots, \widehat{X_l}, \dots, X_n)$ at p_0 . Since the X_i 's enter symmetrically, we can assume, by renumbering, that $l = 1$. Now (29) gives

$$\begin{aligned}
 i^*\{L_{\widetilde{W}}(\widetilde{W} \sqcup \Phi)\}(X_2, \dots, X_n) &= \left(\sum_{j=1}^n \phi^1 \wedge \dots \wedge L_{\widetilde{W}} \phi^j \wedge \dots \wedge \phi^n \right)(W, X_2, \dots, X_n) \quad \text{at } p_0 \\
 &= (L_{\widetilde{W}} \phi^1 \wedge \dots \wedge \phi^n)(W, X_2, \dots, X_n) \\
 &\quad + \sum_{j=2}^n (\phi^1 \wedge \dots \wedge L_{\widetilde{W}} \phi^j \wedge \dots \wedge \phi^n)(W, X_2, \dots, X_n) \quad \text{at } p_0.
 \end{aligned}$$

In computing the first term, the only permutations of (W, X_2, \dots, X_n) that do not give zero are interchanges of W with one X_j ; in the second sum only the given order (W, X_2, \dots, X_n) produces a non-zero result. So

$$\begin{aligned}
 i^*\{L_{\widetilde{W}}(\widetilde{W} \sqcup \Phi)\}(X_2, \dots, X_n) &= \left[(L_{\widetilde{W}} \phi^1)(W) - \sum_{j=2}^n \phi^j(W)(L_{\widetilde{W}} \phi^1)(X_j) \right] \\
 &\quad + \sum_{j=2}^n \phi^1(W)(L_{\widetilde{W}} \phi^j)(X_j) \quad \text{at } p_0 \\
 &= (L_{\widetilde{W}} \phi^1)(W) - \sum_{j=1}^n \phi^j(W)(L_{\widetilde{W}} \phi^1)(X_j) \\
 &\quad + \phi^1(W) \sum_{j=1}^n (L_{\widetilde{W}} \phi^j)(X_j) \quad \text{at } p_0 \\
 &\quad \text{[since } j = 1 \text{ gives the same new term in each sum]} \\
 &= (L_{\widetilde{W}} \phi^1)(W) - (L_{\widetilde{W}} \phi^1) \left(\sum_{j=1}^n \phi^j(W) X_j \right) \\
 &\quad + \phi^1(W) \sum_{j=1}^n (L_{\widetilde{W}} \phi^j)(X_j) \quad \text{at } p_0 \\
 &= (L_{\widetilde{W}} \phi^1)(\perp W) + \phi^1(W) \sum_{j=1}^n [X_j(\phi^j(W)) - \lambda_j] \quad \text{at } p_0 \\
 &\quad \text{[by (19)]}
 \end{aligned}$$

$$\begin{aligned}
&= (L_{\tilde{W}}\phi^1)(\perp W) + \phi^1(W) \sum_{j=1}^n X_j(\phi^j(\top W)) && \text{at } p_0 \\
&\quad [\text{since } \sum_j \lambda_j = 0] \\
&= (W \lrcorner d\phi^1)(\perp W) + d(\tilde{W} \lrcorner \phi^1)(\perp W) \\
&\quad + \phi^1(W) \sum_{j=1}^n X_j(\langle \top W, X_j \rangle) && \text{at } p_0 \\
&= d\phi^1(W, \perp W) + \perp W(\phi^1(\tilde{W})) \\
&\quad + \phi^1(W) \sum_{j=1}^n [\langle \nabla_{X_j} \top W, X_j \rangle + \langle \top W, \nabla_{X_j} X_j \rangle] && \text{at } p_0 \\
&= [W(\phi^1(\perp \tilde{W})) - \perp W(\phi^1(\tilde{W})) - \phi^1([\tilde{W}, \perp \tilde{W}])] + \perp W(\phi^1(\tilde{W})) \\
&\quad + \phi^1(W) \sum_{j=1}^n \langle \nabla_{X_j} \top W, X_j \rangle && \text{at } p_0 \\
&\quad [\text{since } \sum_j \nabla_{X_j} X_j = \eta = 0] \\
&= -\phi^1([\tilde{W}, \perp \tilde{W}]) + \phi^1(W) \sum_{j=1}^n \langle \nabla_{X_j} \top W, X_j \rangle \\
&= \langle \top[\perp \tilde{W}, \top \tilde{W}], X_1 \rangle + \langle \top W, X_1 \rangle \sum_{j=1}^n \langle \nabla_{X_j} \top W, X_j \rangle.
\end{aligned}$$

This is exactly the value of the right side of (30) on X_2, \dots, X_n ; we have thus completed the calculation of the second term in (15).

Finally, we again dispose of the general case, where $W(p_0)$ may be tangent to V , by considering $\mathbf{N} = N \times \mathbb{R}$, with the product metric, and the map $\alpha: (-\varepsilon, \varepsilon) \times M \rightarrow \mathbf{N}$ defined by

$$\alpha(u, p) = (\alpha(u, p), u).$$

We recall that

$$\mathbf{W}(p) = (W(p), 1) \quad \text{and} \quad \boldsymbol{\eta}(p) = (\eta, 0).$$

So $\tilde{\alpha}(0)$ is minimal if $\bar{\alpha}(0)$ is. If \mathbf{R}' is the curvature tensor in \mathbf{N} , then we have

$$\begin{aligned}
\text{Ric}_M(\perp W) &= \text{Ric}_M((\perp W, 1)) \\
&= - \sum_{i=1}^n \langle \mathbf{R}'(\perp W, X_i) X_i, \perp W \rangle - \sum_{i=1}^n \langle \mathbf{R}'(1, X_i) X_i, 1 \rangle,
\end{aligned}$$

for X_1, \dots, X_n an orthonormal basis of M . Using the fact that we have a product metric, we easily find that

$$\begin{aligned}\operatorname{Ric}_M(\perp \mathbf{W}) &= - \sum_{i=1}^n \langle R'(\perp W, X_i) X_i, \perp W \rangle \\ &= \operatorname{Ric}_M(\perp W).\end{aligned}$$

The map $\mathbf{s}(p): M_p \times M_p \rightarrow M_p^\perp$ is obviously given by

$$\mathbf{s}(p)(X, Y) = (s(X, Y), 0), \quad X, Y \in M_p,$$

so the map $\mathbf{A}_{\perp \mathbf{W}}$ is given by

$$\langle \mathbf{A}_{\perp \mathbf{W}}(X), Y \rangle = \langle (s(X, Y), 0), (\perp W, 1) \rangle = \langle s(X, Y), \perp W \rangle = \langle A_{\perp W}(X), Y \rangle.$$

Consequently,

$$\Sigma_2(\perp \mathbf{W}) = \Sigma_2(\perp W).$$

We also have

$$\Delta(\perp \mathbf{W}) = \Delta((\perp W, 1)) = (\Delta(\perp W), 0),$$

and hence

$$\langle \perp \mathbf{W}, \Delta(\perp \mathbf{W}) \rangle = \langle (\perp W, 1), (\Delta(\perp W), 0) \rangle = \langle \perp W, \Delta(\perp W) \rangle.$$

Since we obviously have $\mathbf{T}\mathbf{W} = \mathbf{T}W$, we have

$$\operatorname{div} \mathbf{T}\mathbf{W} \cdot (\mathbf{T}\mathbf{W} \lrcorner \Gamma(0)) = \operatorname{div} \mathbf{T}W \cdot (\mathbf{T}W \lrcorner \Gamma(0)).$$

Finally,

$$\begin{aligned}[\perp \tilde{\mathbf{W}}, \mathbf{T}\tilde{\mathbf{W}}] &= [(\perp \tilde{W}, 1), (\mathbf{T}\tilde{W}, 0)] \\ &= [\perp \tilde{W}, \mathbf{T}\tilde{W}] + [1, \mathbf{T}\tilde{W}] \\ &= [\perp \tilde{W}, \mathbf{T}\tilde{W}],\end{aligned}$$

the second bracket vanishing since there is clearly a coordinate system x^1, \dots, x^m, τ on \mathbf{N} with $\partial/\partial x^1 = \mathbf{T}\tilde{W}$ and $\partial/\partial \tau = 1$. Thus the result for α implies the result for α . ♦

To integrate the result of Theorem 37 succinctly, we introduce the **outward pointing unit normal of ∂M along f** (see the picture on the next page): for each $q \in \partial M$, we define $\mu(q) \in N_{f(q)}$ to be the unit vector tangent to $f(M)$, perpendicular to $f(\partial N)$, and outward pointing. Recall (pg. I.260) that the orientation for ∂M is chosen so that v_1, \dots, v_{n-1} is positively oriented at q if and only if $\mu(q), v_1, \dots, v_{n-1}$ is positively oriented on M .

39. COROLLARY. Let $f: M \rightarrow N$ be a minimal immersion of a compact oriented n -dimensional manifold-with-boundary M into a Riemannian manifold $(N^m, \langle \cdot, \cdot \rangle)$, and let $\alpha: (-\varepsilon, \varepsilon) \times M \rightarrow N$ be a variation of f through immersions. Let W be the variation vector field, let $\tilde{W} = \partial\alpha/\partial u$, and let μ be the outward pointing unit normal of ∂M along f . If $V(\bar{\alpha}(u))$ is the n -dimensional volume of M determined by the metric $\bar{\alpha}(u)^*\langle \cdot, \cdot \rangle$ and the given orientation of M , then

$$\begin{aligned} \left. \frac{d^2 V(\bar{\alpha}(u))}{du^2} \right|_{u=0} &= \int_M [\text{Ric}_M(\perp W) - \Sigma_2(\perp W) - \langle \perp W, \Delta(\perp W) \rangle] dV \\ &\quad + (-1)^{n+1} \int_{\partial M} [\text{div } \top W \cdot \langle \top W, \mu \rangle + \langle \top[\perp \tilde{W}, \top \tilde{W}], \mu \rangle] dV^{n-1}, \end{aligned}$$

where dV is the volume element determined by $f^*\langle \cdot, \cdot \rangle$, and dV^{n-1} is the induced volume element on ∂M . In particular, if α is a variation keeping ∂M fixed, then

$$\left. \frac{d^2 V(\bar{\alpha}(u))}{du^2} \right|_{u=0} = \int_M [\text{Ric}_M(\perp W) - \Sigma_2(\perp W) - \langle \perp W, \Delta(\perp W) \rangle] dV.$$

PROOF. Left to the reader. ♦

Problem 3 shows what our formula reduces to in the case of a geodesic $\gamma: [a, b] \rightarrow N$. Here we will consider the case of a hypersurface $M \subset N$, with $i: M \rightarrow N$ the inclusion map. Then $\perp W = hv$ for some function h , where v is a unit normal vector field. Since

$$\begin{aligned} \perp \nabla'_{X_j(p)}(\perp \nabla'_{X_j} hv) &= \perp \nabla'_{X_j(p)}(X_j(h)v) \\ &= X_j(p)(X_j(h)) \cdot v, \end{aligned}$$

we see that

$$\langle \perp W, \Delta(\perp W) \rangle = h \Delta h.$$

where Δ now denotes the Laplacian on functions, computed by means of the induced metric $i^*\langle \cdot, \cdot \rangle$ on M . So if Σ_2 denotes the sum of the squares of the

eigenvalues of the symmetric map $\Pi: M_p \times M_p \rightarrow \mathbb{R}$, then our integral becomes

$$\int_M [h^2 \operatorname{Ric}_M(v) - h^2 \Sigma_2 - h \Delta h] dV.$$

Suppose in particular, that we consider the variation by parallel surfaces, $\alpha(u, p) = \exp_p u \cdot v(p)$. Then $h = 1$ and (Problem 3-12) $\tilde{W}(u, p)$ is always perpendicular to $\tilde{\alpha}(u)(M)$; so the integral over ∂M drops out, and we obtain

$$\left. \frac{d^2 V(\tilde{\alpha}(u))}{du^2} \right|_{u=0} = \int_M [\operatorname{Ric}_M(v) - \Sigma_2] dV.$$

If N has sectional curvatures ≥ 0 , then $\operatorname{Ric}_M(v) \leq 0$, so we obtain

$$\left. \frac{d^2 V(\tilde{\alpha}(u))}{du^2} \right|_{u=0} \leq 0.$$

Moreover, we have strict inequality unless $\Sigma_2 = 0$, which happens only when $s = 0$, so that our hypersurface is totally geodesic. Thus a non-totally geodesic minimal hypersurface in a space of non-negative sectional curvature always has *greater* volume than nearby parallel surfaces.

Now let us consider a minimal immersion $f: M \rightarrow \mathbb{R}^3$, where M is a compact surface-with-boundary. Let $\alpha: (-\varepsilon, \varepsilon) \times M \rightarrow \mathbb{R}^3$ be a variation of f keeping ∂M fixed, such that $W = hN$ for some function h vanishing on ∂M , where N is a unit normal field. Then our formula becomes

$$\begin{aligned} (1) \quad \left. \frac{d^2 A(\tilde{\alpha}(u))}{du^2} \right|_{u=0} &= \int_M [-h^2(k_1^2 + k_2^2) - h \Delta h] dA \\ &\quad \text{where } k_1 \text{ and } k_2 = -k_1 \text{ are} \\ &\quad \text{the principal curvatures} \\ &= \int_M [2h^2 K - h \Delta h] dA \\ &= \int_M [2h^2 K + \mathbf{I}_f(\operatorname{grad} h, \operatorname{grad} h)] dA, \\ &\quad \text{by Proposition 7-59.} \end{aligned}$$

In particular, consider a compact 2-dimensional manifold-with-boundary $D \subset \mathbb{R}^2$ and a minimal immersion $\Phi: D \rightarrow \mathbb{R}^3$ given by

$$(*) \quad \begin{cases} \Phi^1 = \operatorname{Re} \int \frac{1}{2} F(w)(1 - w^2) dw \\ \Phi^2 = \operatorname{Re} \int \frac{i}{2} F(w)(1 + w^2) dw \\ \Phi^3 = \operatorname{Re} \int F(w)w dw \end{cases}$$

for a nowhere 0 complex analytic function $F: D \rightarrow \mathbb{C}$. For this immersion we have (page 274)

$$(2) \quad I_f = \Phi^*\langle \cdot, \cdot \rangle = \mu(dx \otimes dx + dy \otimes dy),$$

$$\text{where } \mu(z) = \frac{|F(z)|^2(1 + |z|^2)^2}{4}, \quad z = x + iy.$$

We can compute (Problem 5) that the curvature K for the metric $\Phi^*\langle \cdot, \cdot \rangle$ on D is given by

$$(3) \quad K(z) = \frac{-16}{|F(z)|^2(1 + |z|^2)^4}, \quad z = x + iy.$$

Suppose now that we have a variation α of Φ which keeps ∂D fixed, and such that $W(\Phi(z)) = h(z) \cdot N(z)$ for some function $h: D \rightarrow \mathbb{R}$ with $h = 0$ on ∂D . Using (2), we compute, from the last equation in the proof of Proposition 5, that

$$(4) \quad I_f(\text{grad } h, \text{grad } h)(z) = \frac{(h_1^2 + h_2^2)(z)}{\left(\frac{|F(z)|^2(1 + |z|^2)^2}{4}\right)}.$$

Substituting (4) and (3) into (1), and remembering that the volume element dA of I on D is

$$\sqrt{\det(g_{ij})} \, dx \wedge dy = \mu \, dx \wedge dy,$$

we obtain

$$\left. \frac{d^2 A(\bar{\alpha}(u))}{du^2} \right|_{u=0} = \int_D \left[[h_1(x, y)]^2 + [h_2(x, y)]^2 - \frac{8[h(x, y)]^2}{(1 + x^2 + y^2)^2} \right] dx \, dy.$$

Notice that this expression does not involve the original map $(*)$ at all; it involves only the region D , and the function h . If we recall (page 274) that $N = \sigma^{-1}$, we see that D contains the unit disc $B = \{(x, y) : x^2 + y^2 \leq 1\}$ if and only if the normal map N of Φ covers the whole southern hemisphere of the unit sphere.

40. THEOREM (SCHWARZ-RADO). If the interior of D contains the unit disc $B = \{(x, y) : x^2 + y^2 \leq 1\}$, then there is a function $h: D \rightarrow \mathbb{R}$ with $h = 0$ on ∂D such that

$$(1) \quad \int_D \left[h_1^2 + h_2^2 - \frac{8h^2}{(1 + x^2 + y^2)^2} \right] dx \, dy < 0.$$

Consequently, for every nowhere 0 complex analytic function $F: D \rightarrow \mathbb{C}$, the minimal surface $\Phi(D)$ given by $(*)$ does *not* have minimum area among all nearby surfaces with the same boundary.

(Since the solution to the Plateau problem tells us that there is *some* minimal disc with the same boundary as $\Phi(S^1)$, this proves that $\Phi(S^1)$ is the boundary of at least 2 different minimal surfaces.)

PROOF. Let $B(r) = \{(x, y) : x^2 + y^2 \leq r^2\}$, and define $h^r : B(r) \rightarrow \mathbb{R}$ by

$$(2) \quad h^r(x, y) = \frac{x^2 + y^2 - r^2}{x^2 + y^2 + r^2}.$$

Set

$$(3) \quad I(r) = \int_{B(r)} \left[(h^r_1)^2 + (h^r_2)^2 - \frac{8(h^r)^2}{(1 + x^2 + y^2)^2} \right] dx dy.$$

Substituting (2) into (3), we obtain the explicit formula

$$I(r) = \int_{B(r)} \frac{16(x^2 + y^2)r^4}{(x^2 + y^2 + r^2)^4} dx dy - \int_{B(r)} \frac{8(x^2 + y^2 - r^2)^2}{(x^2 + y^2 + r^2)^2(x^2 + y^2 + 1)^2} dx dy.$$

Making the substitution $x = u \cdot r$, $y = v \cdot r$, we get

$$I(r) = \int_B \frac{16(u^2 + v^2)}{(u^2 + v^2 + 1)^4} du dv - \int_B \frac{8(u^2 + v^2 - 1)^2 r^2}{(u^2 + v^2 + 1)^2(u^2 r^2 + v^2 r^2 + 1)^2} du dv.$$

Finally, computing $I'(1)$ by Leibniz's Rule, we obtain

$$I'(1) = 16 \int_B \frac{(u^2 + v^2 - 1)^3}{(u^2 + v^2 + 1)^5} du dv < 0.$$

On the other hand, we claim that $I(1) = 0$. To prove this, we use Proposition 7-59 and the fact that $h^r = 0$ on $\partial B(r)$ to write (3) as

$$I(r) = - \int_{B(r)} h^r \left[h^r_{11} + h^r_{22} + \frac{8h^r}{(1 + x^2 + y^2)^2} \right] dx dy;$$

then we just compute that the term in brackets is 0 for h^1 .

Since $I(1) = 0$ and $I'(1) < 0$, there is a number $r_0 > 1$ such that $I(r) < 0$ for $1 < r < r_0$. Now there is some r with $1 < r < r_0$ such that $D \supset B(r)$. Define h on D by

$$h(x, y) = \begin{cases} h^r(x, y) & (x, y) \in B(r) \\ 0 & \text{otherwise.} \end{cases}$$

This h has all the desired properties, except that the first partial derivatives of h are discontinuous on $B(r)$. However, it is easy to see that we can round off h to a C^∞ function without changing the sign of the integral in (1). ♦

PROBLEMS

1. Show that formula (*) on page 274 gives

$$\text{a catenoid for } F(w) = \frac{1}{w^2}$$

$$\text{a helicoid for } F(w) = \frac{i}{w^2}$$

$$\text{Scherk's minimal surface for } F(w) = \frac{4}{1-w^4}.$$

2. Let $f: \mathbb{R} \rightarrow \mathbb{R}$ be convex.

(a) We have

$$f'(x^+) = \inf_{h>0} \frac{f(x+h) - f(x)}{h}$$

$$f'(x^-) = \sup_{h>0} \frac{f(x+h) - f(x)}{h}.$$

(b) If $f'(x)$ exists for all x , then f' is continuous. *Hint:* Consider $h > 0$, say, with $[f(x+h) - f(x)]/h < f'(x) + \varepsilon$.

3. Let $\gamma: [a, b] \rightarrow N$ be an arclength parameterized geodesic, with unit tangent vector $V = d\gamma/dt$, and let $\alpha: (-\varepsilon, \varepsilon) \times [a, b] \rightarrow V$ be a variation, with variation vector field \tilde{W} .

(a) If Z is a vector field along γ with $\langle V, Z \rangle = 0$, then $\perp \nabla'_V Z = \nabla'_V Z$.

(b) $\Delta(\perp W) = D^2 \perp W / dt^2$.

(c) We have

$$\left. \frac{d^2 L(\tilde{\alpha}(u))}{du^2} \right|_{u=0} = \int_a^b - \left\langle \frac{D^2 \perp W}{dt^2}, \perp W(t) \right\rangle - \langle R'(W, V)V, W \rangle(t) dt$$

$$+ \langle \nabla_V \top W, V \rangle \cdot \langle \top W, V \rangle + \langle [\perp W, \top W], V \rangle \Big|_a^b.$$

(d) Let

$$B = \langle \nabla_V \top W, V \rangle \cdot \langle \top W, V \rangle + \langle [\perp W, \top W], V \rangle$$

$$= \langle \nabla_V \top W, \top W \rangle + \langle \nabla_{\perp W} \top W, V \rangle - \langle \nabla_{\top W} \perp W, V \rangle.$$

Noting that $\top W$ is a multiple of V , say $\top W = hV$, show that

$$\langle \nabla_{\top W} \perp W, V \rangle = 0 \quad \text{and} \quad \langle \nabla_V \top W, \top W \rangle = \langle \nabla_{\top W} \top W, V \rangle.$$

Thus

$$\begin{aligned} B &= \langle \nabla_{\mathbf{T}W} \mathbf{T}W, V \rangle + \langle \nabla_{\perp W} \mathbf{T}W, V \rangle = \langle \nabla_W \mathbf{T}W, V \rangle \\ &= \langle \nabla_W W, V \rangle - \langle \nabla_W \perp W, V \rangle \\ &= \langle \nabla_W W, V \rangle + \langle \nabla_V \perp W, \perp W \rangle. \end{aligned}$$

(e) Conclude that

$$\begin{aligned} \frac{d^2 L(\tilde{\alpha}(u))}{du^2} \Big|_{u=0} &= \int_a^b \left\langle \frac{D\perp W}{dt}, \frac{D\perp W}{dt} \right\rangle - \langle R'(W, V)V, W \rangle(t) dt \\ &\quad + \langle \nabla_W W, V \rangle \Big|_a^b. \end{aligned}$$

4. If $M \subset \mathbb{R}^3$ is a minimal surface, then at any point $p \in M$ the Gaussian curvature $K(p)$ is given by

$$K(p) = -\frac{\langle \nu_* X, \nu_* X \rangle}{\langle X, X \rangle} \quad \text{for any } X \in M_p.$$

Hint: The numerator is $\text{III}(X, X)$.

5. Consider a minimal immersion $\Phi: V \rightarrow \mathbb{R}^3$ given by (*) on page 274, so that $N = \sigma^{-1}$ and $g_{ij} = \mu \delta_{ij}$, where

$$\mu(z) = \frac{|F(z)|^2(1 + |z|^2)^2}{4}.$$

Use Problems 4 and 7-20 to show that

$$\begin{aligned} K(z) &= -\left(\frac{2}{1 + |z|^2}\right)^2 \Big/ \mu(z) \\ &= \frac{-16}{|F(z)|^2(1 + |z|^2)^4}. \end{aligned}$$

6. (a) Let $M \subset \mathbb{R}^3$ be a minimal surface with $K < 0$ everywhere, and consider an imbedding $f: U \rightarrow M$ whose parameter lines are lines of curvature. Using the formulas on pg. III.217, show that if $k_1 > 0$ is the positive principal curvature, then

$$E(s, t) = S(s)/k_1(s, t), \quad G(s, t) = T(t)/k_1(s, t)$$

for certain functions $S, T > 0$. Then show that there is a new imbedding with

$$E = G = \frac{1}{k_1}.$$

Conclude that if $\langle \cdot, \cdot \rangle$ is the metric on M , then

$$\sqrt{-K} \langle \cdot, \cdot \rangle$$

is a flat metric (Ricci).

(b) Let $\langle \cdot, \cdot \rangle$ be a metric on a 2-dimensional manifold M such that $K < 0$ and $\sqrt{-K} \langle \cdot, \cdot \rangle$ is flat. Thus there is a coordinate system (u, v) such that

$$\begin{aligned} \sqrt{-K} \langle \cdot, \cdot \rangle = du \otimes du + dv \otimes dv &\implies \langle \cdot, \cdot \rangle = \frac{1}{\sqrt{-K}} (du \otimes du + dv \otimes dv) \\ &= g(du \otimes du + dv \otimes dv), \text{ say.} \end{aligned}$$

Using the formula on pg. III.217, show that

$$K = -\frac{1}{2g} \left[\left(\frac{g_v}{g} \right)_v + \left(\frac{g_u}{g} \right)_u \right].$$

Then show that there is an imbedding $f: U \rightarrow \mathbb{R}^3$ with

$$\begin{aligned} E = G &= \frac{1}{\sqrt{-K}}, & F &= 0 \\ l &= 1, & n &= -1, & m &= 0. \end{aligned}$$

Thus $f(U)$ is a minimal surface isometric to M .

TABLE OF CONTENTS

Although the chapters are not divided into sections,
except for the subdivisions of Chapters 10 and 13,
the listing for each chapter gives some indication
which topics are treated, and on what pages.

CHAPTER 10. AND NOW A BRIEF MESSAGE FROM OUR SPONSOR

1. FIRST ORDER PDE's	1
Linear first order PDE's; characteristic curves; Cauchy problem	
for free initial curves	4
Quasi-linear first order PDE's; characteristic curves; Cauchy problem	
for free initial conditions; characteristic initial conditions	9
General first order PDE's; Monge cone; characteristic curves	
of a solution; characteristic strips; Cauchy problem for	
free initial data; characteristic initial data	13
First order PDE's in n variables	26
2. FREE INITIAL MANIFOLDS FOR HIGHER ORDER EQUATIONS	29
3. SYSTEMS OF FIRST ORDER PDE's	36
4. THE CAUCHY-KOWALEWSKI THEOREM	38
5. CLASSIFICATION OF SECOND ORDER PDE's	
Classification of semi-linear equations	47
Reduction to normal forms	50
Classification of general second order equations	56
6. THE PROTOTYPICAL PDE's OF PHYSICS	
The wave equation; the heat equation; Laplace's equation	59
Elementary properties	66
7. HYPERBOLIC SYSTEMS IN TWO VARIABLES	72
8. HYPERBOLIC SECOND ORDER EQUATIONS IN TWO VARIABLES	
First reduction of the problem	81
New system of characteristic equations	84

Characteristic initial data	96
Monge-Ampère equations	97
9. ELLIPTIC SOLUTIONS OF SECOND ORDER EQUATIONS	
IN TWO VARIABLES	98
Addendum 1. Differential systems; the Cartan-Kähler Theorem . . .	110
Addendum 2. An elementary maximum principal	126
Problem	132
CHAPTER 11. EXISTENCE AND NON-EXISTENCE OF ISOMETRIC IMBEDDINGS	
Non-imbeddability theorems; exteriorly orthogonal bilinear forms; index of nullity and index of relative nullity	133
The Darboux equation	142
Burstin-Janet-Cartan Theorem	147
Addendum. The embedding problem via differential systems . . .	157
Problems	165
CHAPTER 12. RIGIDITY	
Rigidity in higher dimensions; type number	167
Bendings, warpings, and infinitesimal bendings	170
\mathbb{R}^3 -valued differential forms, the support function, and Minkowski's formulas	181
Infinitesimal rigidity of convex surfaces	186
Cohn-Vossen's Theorem	192
Minkowski's Theorem	200
Christoffel's Theorem	204
Other problems, solved and unsolved	206
Local problems; the role of the asymptotic curves	215
Other classical results	221
E. E. Levi's Theorems and Schilt's Theorem	227
Surfaces in S^3 and H^3	235
Rigidity for higher codimension	247
Addendum. Infinitesimal bendings of rotation surfaces	253
Problems	261

CHAPTER 13. THE GENERALIZED GAUSS-BONNET THEOREM AND WHAT IT MEANS FOR MANKIND

Historical remarks	263
1. OPERATIONS ON BUNDLES	
Bundle maps and principal bundle maps; Whitney sums and induced bundles; the covering homotopy theorem	265
2. GRASSMANNIANS AND UNIVERSAL BUNDLES	273
3. THE PFAFFIAN	284
4. DEFINING THE EULER CLASS IN TERMS OF A CONNECTION	
The Euler class	291
The class $C(\xi)$	294
The Gauss-Bonnet-Chern Theorem	297
5. THE CONCEPT OF CHARACTERISTIC CLASSES	302
6. THE COHOMOLOGY OF HOMOGENEOUS SPACES	
The C^∞ structure of homogeneous spaces	304
Invariant forms	308
7. A SMATTERING OF CLASSICAL INVARIANT THEORY	
The Capelli identities	317
The first fundamental theorem of invariant theory for $O(n)$ and $SO(n)$	326
8. AN EASIER INVARIANCE PROBLEM	330
9. THE COHOMOLOGY OF THE ORIENTED GRASSMANNIANS	
Computation of the cohomology; Pontryagin classes	337
Describing the characteristic classes in terms of a connection	345
10. THE WEIL HOMOMORPHISM	353
11. COMPLEX BUNDLES	
Hermitian inner products, the unitary group, and complex Grassmannians	356
The cohomology of the complex Grassmannians; Chern classes	360
Relations between the Chern classes and the Pontryagin and Euler classes	365
12. VALEDICTORY	369
Addendum 1. Invariant theory for the unitary group	372
Addendum 2. Recovering the differential forms; the Gauss-Bonnet-Chern Theorem for manifolds-with-boundary	380

DIFFERENTIAL GEOMETRY

VOLUME FIVE

CHAPTER 10

AND NOW A BRIEF MESSAGE FROM OUR SPONSOR

Partial differential equations have played a decisive role in our investigations ever since they were first introduced in Chapter 6 of Volume I. To be sure, at times we have suppressed the equations themselves in favor of a more geometric conception involving k -dimensional distributions, and on other occasions we have instead expressed things in terms of differential forms. But, in one form or another, the Frobenius Theorem (which represents everything we know about partial differential equations) was used in discussing Lie groups, ordinary and affine theory of curves and surfaces in space (where Lie group methods were used), in all our proofs of the Test Case, in the proof of the Fundamental Theorem of Surface Theory, and in the generalizations of this theorem which were given in Chapter 7. The partial differential equations involved are of the form

$$\frac{\partial \alpha^i}{\partial x_j}(x_1, \dots, x_m) = f_j^i(x_1, \dots, x_m, \alpha^1(x_1, \dots, x_m), \dots, \alpha^n(x_1, \dots, x_m))$$

$$i = 1, \dots, n; \quad j = 1, \dots, m.$$

Now it's really rather laughable to call these things partial differential equations at all. True, we are considering functions α^i defined on \mathbb{R}^n , and therefore partial derivatives are involved, but the equations do not posit any relationship between *different* partial derivatives; this comes out quite clearly in the proof, where the equations are reduced to ordinary differential equations. The only reason we get anything interesting at all in this situation is because we are dealing with a *system* of equations, and this system is "overdetermined": there are more equations (namely mn) than there are unknown functions (namely n). Our particular overdetermined system happens to be one where it is not too hard to determine the additional "integrability conditions" which must hold for the functions f_j^i if the strain of satisfying so many equations is not to hopelessly overburden the poor functions α^i .

With only this superficial knowledge of partial differential equations, one can make one's way through a good part of differential geometry ("*the good part*", you may be inclined to say after looking at this chapter). But there are some topics in differential geometry, to be covered in the next two chapters, where

a more intimate acquaintance with partial differential equations is required. It should be said right away, that even in the next two chapters there are only a few occasions where this knowledge is necessary, and one could easily decide to take on faith any theorems from this chapter which happen to be quoted later. On the other hand, many theorems cannot even be stated without some definitions that arise in the first attempts to understand partial differential equations; these definitions involve basic facts about the behavior of partial differential equations, and this behavior is often reflected in geometric phenomena in a surprisingly nice way.

This chapter is not meant to be a substitute for a course in partial differential equations; we will try to reach in as short a space as possible those particular properties of partial differential equations which will be of importance to us in the next two chapters, even if they are of only secondary importance to analysis. Consequently, we will omit much material that is contained in elementary courses, and at the same time prove special cases of results which are usually found only in more advanced treatments, where they are proved in much greater generality, and with much more effort. (Just to keep the presentation from being too one-sided, passing mention has sometimes been given to matters which are of great importance to analysts, but of no importance to us). Since we are going to be totally immersed in the study of partial differential equations for quite a while, we might as well admit it, and henceforth resort to the standard abbreviation PDE.

A few general considerations might be made before we begin in earnest. When we consider an ordinary differential equation

$$u'(x) = f(x, u(x)),$$

we find that there are solutions u with any desired value for $u(x_0)$. This dependence on the “initial condition” $u(x_0)$ usually manifests itself, if we explicitly solve the equation, by the presence of an arbitrary constant of integration. For example, the equation

$$\frac{du}{dx} = -u^2 \quad \left(\Rightarrow \frac{du}{-u^2} = dx \Rightarrow \frac{1}{u} = x + C \right)$$

has the “general” solution

$$u(x) = \frac{1}{x + C},$$

which gives all desired initial conditions $u(x_0)$ except $u(x_0) = 0$; for this one needs the “singular” solution $u(x) = 0$. Equations of order n , on the other hand, will involve n constants of integration.

When we solve a PDE, we usually obtain arbitrary *functions* in the answer. For example, to be as simple-minded about the thing as we can, we note that the equation

$$\frac{\partial u}{\partial y}(x, y) = 0$$

has the solutions $u(x, y) = A(x)$; the only restrictions on A are ones which follow from restrictions we might choose to place on u (e.g., that u be differentiable with respect to x). The equally stupid looking, but actually quite important, second order equation

$$\frac{\partial^2 u}{\partial x \partial y}(x, y) = 0$$

leads to

$$\frac{\partial u}{\partial x}(x, y) = \alpha(x),$$

and hence to

$$u(x, y) = A(x) + B(y), \quad A'(x) = \alpha(x).$$

Without belaboring the point any further, we simply note that when we look for precise theorems, we should expect the hypotheses to reflect the presence of these “arbitrary functions” in the same way that the precise theorem for ordinary differential equations reflects the presence of arbitrary constants.

1. FIRST ORDER PDE's

In this section we will consider those equations which involve a function u on \mathbb{R}^n and only its first partial derivatives u_{x_i} . For simplicity of writing, and convenience of visualization, we will first deal exclusively with the case of \mathbb{R}^2 , denoting a typical point of \mathbb{R}^2 by (x, y) and adopting the standard notation

$$u_x = p, \quad u_y = q.$$

By a **first order PDE** we then mean an equation of the form

$$F(x, y, u(x, y), u_x(x, y), u_y(x, y)) = 0,$$

or, to use the standard abbreviated form,

$$F(x, y, u, p, q) = 0.$$

It will be convenient to denote the various partial derivatives of F by F_x , F_y , F_u , F_p , and F_q . Naturally, the function $F: \mathbb{R}^5 \rightarrow \mathbb{R}$ shouldn't be too badly

behaved; for example, it wouldn't be very interesting if F were never 0. Just what hypotheses we really need will come out soon enough. To begin with, we might imagine that F is differentiable and satisfies $F_p \neq 0$ or $F_q \neq 0$, so that by the implicit function theorem we can solve for p in terms of q , or *vice versa*. Our main result is, that we can always completely reduce any first order PDE to a system of ordinary differential equations. This holds both in a "practical" and in a theoretical sense: We can actually write down a system of ordinary differential equations whose solutions, if we can find them, will give us the solution of our original problem; and the method by which this is done enables us to state and prove exact theorems. We will not deal at the very outset with the most general first order PDE, but will approach it in stages.

We consider first the most general **linear first order PDE**

$$(1) \quad A(x, y)u_x(x, y) + B(x, y)u_y(x, y) = C(x, y)u(x, y) + D(x, y).$$

Usually this is simply written

$$A(x, y)u_x + B(x, y)u_y = C(x, y)u + D(x, y),$$

with the arguments (x, y) appearing in A , B , C , and D just to emphasize that we are not considering an equation like $A(x, y, u(x, y))u_x + \dots$.

Consider the vector field X on \mathbb{R}^2 defined by

$$(2) \quad X = A \frac{\partial}{\partial x} + B \frac{\partial}{\partial y}.$$

The value of X at (x_0, y_0) is

$$A(x_0, y_0) \frac{\partial}{\partial x} \Big|_{(x_0, y_0)} + B(x_0, y_0) \frac{\partial}{\partial y} \Big|_{(x_0, y_0)};$$

using the standard identification of the tangent space $\mathbb{R}^2_{(x_0, y_0)}$ with \mathbb{R}^2 , we can also write

$$X(x_0, y_0) = (A(x_0, y_0), B(x_0, y_0)).$$

We will call X the **characteristic vector field** of equation (1); the integral curves of this vector field are called the **characteristic curves** of equation (1). Thus $c = (c_1, c_2)$ is a characteristic curve if and only if

$$(3) \quad \frac{dc_1(t)}{dt} = A(c(t)), \quad \frac{dc_2(t)}{dt} = B(c(t)).$$

We then have, for any C^1 function $u: \mathbb{R}^2 \rightarrow \mathbb{R}$,

$$\begin{aligned} \frac{du(c(t))}{dt} &= u_x(c(t)) \frac{dc_1(t)}{dt} + u_y(c(t)) \frac{dc_2(t)}{dt} \\ &= A(c(t)) \cdot u_x(c(t)) + B(c(t)) \cdot u_y(c(t)). \end{aligned}$$

So any solution u of equation (1) satisfies

$$(4) \quad \frac{du(c(t))}{dt} = C(c(t)) \cdot u(c(t)) + D(c(t)) \quad \text{for any characteristic curve } c.$$

For any fixed characteristic curve $t \mapsto c(t)$, equation (4) is an ordinary differential equation for the function $u \circ c$. Consequently, $u \circ c$ is uniquely determined

once $u(c(t_0))$ is specified. In other words, once we prescribe a value $u(x_0, y_0)$ for a solution u of equation (1), the solution u will then be completely determined along the characteristic curve c through (x_0, y_0) .

Now suppose we have any curve σ which cuts a family of characteristic curves.

If we arbitrarily specify the values of u at each point of σ , then the solution u will be determined in a neighborhood of σ . Moreover, we ought to be able to produce this solution u simply by solving equation (4) for each of the characteristic curves through each point of σ . Of course, we clearly have to rule out the possibility that a portion of σ itself is a characteristic curve, for then

we could not arbitrarily specify the values of u along σ . We even have to rule out the possibility that σ is tangent to some integral curve c at some point $(x_0, y_0) = c(t_0)$; for in this case, the directional derivative $X(x_0, y_0)(u)$ would

be determined both by equation (4) and (in a possibly conflicting way) by the arbitrarily assigned values of u along σ . We must thus assume that the vectors

$$\sigma'(s) = (\sigma_1'(s), \sigma_2'(s)) \quad \text{and} \quad (A(\sigma(s)), B(\sigma(s)))$$

are always linearly independent. Equivalently, we must require that

$$0 \neq \det \begin{pmatrix} \sigma_1'(s) & A(\sigma(s)) \\ \sigma_2'(s) & B(\sigma(s)) \end{pmatrix} = \sigma_1'(s)B(\sigma(s)) - \sigma_2'(s)A(\sigma(s))$$

for all s . In particular, $\sigma'(s) \neq (0, 0)$ so σ is an imbedding. Although we will later have a much more general result, we summarize this information in a theorem, in order to get all the details cleaned up before we carry the discussion any further.

1. THEOREM. Let A , B , C , and D be C^k functions defined in an open set $U \subset \mathbb{R}^2$, and let $\sigma: [a, b] \rightarrow U$ be a one-one C^k curve such that

$$\sigma_1'(s)B(\sigma(s)) \neq \sigma_2'(s)A(\sigma(s)) \quad \text{for all } s \in [a, b].$$

Let $\mathring{u}: [a, b] \rightarrow \mathbb{R}$ be a C^k function. Then there is a C^k function u , defined in a neighborhood V of $\sigma([a, b])$, such that u satisfies

$$(1) \quad A \cdot u_x + B \cdot u_y = C \cdot u + D \quad \text{on } V,$$

with the initial condition

$$u(\sigma(s)) = \mathring{u}(s) \quad \text{for all } s \in [a, b].$$

Moreover, any two functions u with this property agree on a neighborhood of $\sigma([a, b])$.

PROOF. There is a C^k map

$$\gamma : [a, b] \times (-\varepsilon, \varepsilon) \rightarrow U$$

such that each curve

$$t \mapsto \gamma(s, t)$$

is a characteristic curve with

$$\gamma(s, 0) = \sigma(s).$$

Clearly

$$\frac{\partial \gamma}{\partial s}(s, 0) = \sigma'(s) = (\sigma_1'(s), \sigma_2'(s))$$

$$\frac{\partial \gamma}{\partial t}(s, 0) = (A(\sigma(s)), B(\sigma(s))).$$

So, by the hypothesis on σ , the Jacobian of γ at $(s, 0)$ is always non-singular; consequently, if ε is sufficiently small, then γ is a C^k diffeomorphism onto a neighborhood V of $\sigma([a, b])$.

By choosing ε still smaller, if necessary, we can insure that for each $s \in [a, b]$ there is a C^k function $\beta_s : (-\varepsilon, \varepsilon) \rightarrow \mathbb{R}$ satisfying

$$\begin{cases} \frac{d\beta_s(t)}{dt} = C(\gamma(s, t)) \cdot \beta_s(t) + D(\gamma(s, t)) \\ \beta_s(0) = \dot{u}(s) \end{cases}$$

[this is just the equation (4) which should be satisfied by $u \circ c$ along the integral curve $t \mapsto \gamma(s, t)$]. We would actually like to know that $\beta_s(t)$ is C^k as a function of s and t ; in other words, if we define $\beta : [a, b] \times (-\varepsilon, \varepsilon) \rightarrow \mathbb{R}$ by

$$\beta(s, t) = \beta_s(t),$$

then we would like to know that β is C^k . To prove this, we must consider the equation “depending on parameters”

$$\begin{cases} \alpha(0, s, r) = r & \text{for } r \in \mathbb{R} \\ \frac{\partial}{\partial t} \alpha(t, s, r) = C(\gamma(s, t)) \cdot \alpha(t, s, r) + D(\gamma(s, t)). \end{cases}$$

Problem I.5-5 shows that α is C^k ; consequently

$$\beta(s, t) = \alpha(t, s, \dot{u}(s))$$

is also C^k .

Now the solution u , if it exists, clearly must be the C^k function

$$u(x, y) = \beta(\gamma^{-1}(x, y)) \quad \text{or equivalently} \quad u(\gamma(s, t)) = \beta(s, t).$$

To prove that u really is a solution, we note that through any point $(x, y) \in V$ there is a characteristic curve $t \mapsto \gamma(s, t)$, and that

$$\begin{aligned} \frac{du(\gamma(s, t))}{dt} &= \frac{d\beta(s, t)}{dt} = C(\gamma(s, t)) \cdot \beta(s, t) + D(\gamma(s, t)) \\ &= C(\gamma(s, t)) \cdot u(\gamma(s, t)) + D(\gamma(s, t)), \end{aligned}$$

while we also have

$$\begin{aligned} \frac{du(\gamma(s, t))}{dt} &= u_x(\gamma(s, t)) \cdot \frac{\partial \gamma_1}{\partial t}(s, t) + u_y(\gamma(s, t)) \cdot \frac{\partial \gamma_2}{\partial t}(s, t) \\ &= u_x(\gamma(s, t)) \cdot A(\gamma(s, t)) + u_y(\gamma(s, t)) \cdot B(\gamma(s, t)), \end{aligned}$$

since $t \mapsto \gamma(s, t)$ is a characteristic curve. ♦

Notice that Theorem 1 involves exactly the sort of “arbitrary function” that our general considerations would lead us to expect: in a neighborhood of the “initial curve” σ , the solution u is uniquely determined by the “initial condition” $u(\sigma(s)) = \hat{u}(s)$. The only requirement is that σ be nowhere tangent to a characteristic curve; we will express this by saying that σ is **free** (sometimes the term “non-characteristic” is used, but this seems a little misleading). In general, the problem of finding a solution of a PDE with an appropriate initial condition is called the “Cauchy problem” for this equation. Thus we have solved the Cauchy problem for the linear PDE (1) for any initial condition along any free curve. In particular, we can solve the Cauchy problem along the x -axis $\sigma(s) = (s, 0)$ if the x -axis is free, which is equivalent to the condition that $B \neq 0$ along the x -axis. In this case we can use the given equation (1) to solve for u_y in terms of u_x along the x -axis:

$$u_y = -\frac{A}{B}u_x + \frac{C}{B}u + \frac{D}{B}.$$

If we were interested in the Cauchy problem only along the x -axis, then we could simply demand this very natural condition in our hypotheses, and not mention the characteristic curves at all; but the characteristic curves are still the most important ingredient in the proof, and their generalizations will play decisive roles in all other equations we discuss.

If our initial curve σ actually happens to be a characteristic curve (thus failing in the worst possible way to be free), then we will be unable to solve the Cauchy problem, and this inability will be manifested in the worst possible way: the possible initial condition along σ is almost uniquely determined—it is determined by the value at only one point, by the equation (4). On the other hand, if we are given an initial condition \bar{u} along σ which does satisfy (4), then there will be infinitely many solutions u with this initial condition; for we can consider any free curve ρ with $\rho(0) = \sigma(0)$, and choose any initial data ϕ along ρ

with $\phi(0) = \bar{u}(0)$. Thus, the characteristic curves are the places where different solutions agree.

From Theorem 1 we can see immediately that an arbitrary linear first order PDE has, in common with the simple-minded equation $\partial u / \partial y = 0$, a property which sharply distinguishes it from an *ordinary* differential equation

$$u'(x) = f(x, u(x)).$$

For the ordinary differential equation, any solution u will clearly be at least one time more differentiable than f is, and if f is analytic, the solution will also be analytic (Problem I.6-9). But there are solutions of the equation in Theorem 1 which are only C^l ($1 \leq l \leq \infty$) even when A, B, C, D are C^k ($l < k \leq \omega$). For we may choose σ to be a C^k curve and \bar{u} to be a function which is C^l , but not C^{l+1} ; then the solution u cannot be C^{l+1} , since its restriction to the C^k curve σ is not C^{l+1} .

We next consider the most general **quasi-linear first order PDE**

$$A(x, y, u(x, y))u_x(x, y) + B(x, y, u(x, y))u_y(x, y) = C(x, y, u(x, y)),$$

or, more briefly,

$$A(x, y, u)u_x + B(x, y, u)u_y = C(x, y, u).$$

The functions A , B , and C are now defined on \mathbb{R}^3 , and we consider the vector field X in \mathbb{R}^3 defined by

$$(2) \quad X = A \frac{\partial}{\partial x} + B \frac{\partial}{\partial y} + C \frac{\partial}{\partial z}.$$

This vector field will be called the **characteristic vector field** of equation (1); the integral curves of X are called the **characteristic curves** of equation (1). Thus $c = (c_1, c_2, c_3)$ is a characteristic curve if and only if

$$(3) \quad \frac{dc_1(t)}{dt} = A(c(t)), \quad \frac{dc_2(t)}{dt} = B(c(t)), \quad \frac{dc_3(t)}{dt} = C(c(t)).$$

The slight discrepancy between this terminology and that adopted in the linear case is easily explained. Notice that if A and B depend only on x and y , then all characteristic vectors $X(x_0, y_0, z_0)$ have the same projection on the (x, y) -plane, namely $(A(x_0, y_0), B(x_0, y_0))$. So the characteristic curves of a linear equation are really the projections on the (x, y) -plane of the characteristic curves in \mathbb{R}^3 .

For the quasi-linear PDE (1), the characteristic curves in \mathbb{R}^3 have the following significance. Any C^1 function $u: \mathbb{R}^2 \rightarrow \mathbb{R}$ determines a surface $M_u = \{(x, y, u(x, y))\} \subset \mathbb{R}^3$, and the vector

$$(u_x(x, y), u_y(x, y), -1)$$

is normal to M_u at $(x, y, u(x, y))$. Equation (1) is therefore equivalent to saying that $X(x, y, u(x, y))$ lies in the tangent space of M_u at $(x, y, u(x, y))$. So the

characteristic vectors at the various points of M_u give a vector field on M_u . Thus M_u is the union of integral curves of this vector field; that is, M_u is the union of characteristic curves. If we are given an arbitrary initial condition \hat{u} along an initial curve σ in \mathbb{R}^2 , then we ought to be able to construct a solution u passing through the curve $s \mapsto (\sigma_1(s), \sigma_2(s), \hat{u}(s))$ in \mathbb{R}^3 simply by taking the union of the characteristic curves through all the points of this curve. We will clearly have to require that the vectors $(\sigma_1'(s), \sigma_2'(s))$ and $(A(\sigma_1(s), \sigma_2(s), \hat{u}(s)), B(\sigma_1(s), \sigma_2(s), \hat{u}(s)))$ are linearly independent for all s .

2. THEOREM. Let A , B , and C be C^k functions defined in an open set $U \subset \mathbb{R}^3$. Let $\sigma: [a, b] \rightarrow \mathbb{R}^2$ be a one-one C^k function, and $\dot{u}: [a, b] \rightarrow \mathbb{R}$ a C^k function such that $(\sigma_1(s), \sigma_2(s), \dot{u}(s)) \in U$ for all $s \in [a, b]$. Suppose moreover that

$$\sigma_1'(s) \cdot B(\sigma_1(s), \sigma_2(s), \dot{u}(s)) \neq \sigma_2'(s) \cdot A(\sigma_1(s), \sigma_2(s), \dot{u}(s)) \quad \text{for all } s \in [a, b].$$

Then there is a C^k function u , defined in a neighborhood V of $\sigma([a, b])$, which satisfies the equation

$$(I) \quad A(x, y, u)u_x + B(x, y, u)u_y = C(x, y, u) \quad \text{on } V,$$

with the initial condition

$$u(\sigma(s)) = \dot{u}(s) \quad \text{for all } s \in [a, b].$$

Moreover, any two functions u with this property agree on a neighborhood of $\sigma([a, b])$.

PROOF. By Problem I.5-5 there is a C^k function $\alpha = (\alpha_1, \alpha_2, \alpha_3)$ with

$$(*) \quad \begin{cases} \alpha(0, s, r) = r & \text{for } r \in \mathbb{R}^3 \\ \frac{\partial}{\partial t} \alpha_1(t, s, r) = A(\alpha(t, s, r)) \\ \frac{\partial}{\partial t} \alpha_2(t, s, r) = B(\alpha(t, s, r)) \\ \frac{\partial}{\partial t} \alpha_3(t, s, r) = C(\alpha(t, s, r)). \end{cases}$$

Let

$$\beta(s, t) = \alpha(t, s, \sigma_1(s), \sigma_2(s), \dot{u}(s)),$$

so that β is also C^k . In particular,

$$\begin{aligned}\beta(s, 0) &= (\sigma_1(s), \sigma_2(s), \overset{\circ}{u}(s)) \\ &= \bullet, \quad \text{for short}\end{aligned}$$

[so for each s , the curve $t \mapsto \beta(s, t)$ is a characteristic curve through \bullet]. If we define

$$\gamma(s, t) = (\beta_1(s, t), \beta_2(s, t)) \in \mathbb{R}^2,$$

then the Jacobian of γ at $(s, 0)$ is

$$\begin{aligned}\begin{pmatrix} \frac{\partial \beta_1}{\partial s}(s, 0) & \frac{\partial \beta_1}{\partial t}(s, 0) \\ \frac{\partial \beta_2}{\partial s}(s, 0) & \frac{\partial \beta_2}{\partial t}(s, 0) \end{pmatrix} &= \begin{pmatrix} \sigma_1'(s) & \frac{\partial \alpha_1}{\partial t}(0, s, \bullet) \\ \sigma_2'(s) & \frac{\partial \alpha_2}{\partial t}(0, s, \bullet) \end{pmatrix} \\ &= \begin{pmatrix} \sigma_1'(s) & A(\bullet) \\ \sigma_2'(s) & B(\bullet) \end{pmatrix} \quad \text{by } (*),\end{aligned}$$

and this is non-singular, by hypothesis. So if ε is sufficiently small, then $\gamma: [a, b] \times (-\varepsilon, \varepsilon) \rightarrow \mathbb{R}^2$ is a C^k diffeomorphism onto a neighborhood V of $\sigma([a, b])$.

The solution u , if it exists, clearly must be the C^k function

$$u(x, y) = \beta_3(\gamma^{-1}(x, y)) \quad \text{or equivalently} \quad u(\gamma(s, t)) = \beta_3(s, t).$$

To prove that u is a solution, we note that for any point $(x, y) \in V$, there is a characteristic curve $t \mapsto \beta(s, t)$ through $(x, y, u(x, y))$, and that

$$\frac{du(\gamma(s, t))}{dt} = \frac{d\beta_3(s, t)}{dt} = C(\beta(s, t)) \quad \text{by } (*),$$

while we also have

$$\begin{aligned}\frac{du(\gamma(s, t))}{dt} &= u_x(\gamma(s, t)) \cdot \frac{\partial \gamma_1}{\partial t}(s, t) + u_y(\gamma(s, t)) \cdot \frac{\partial \gamma_2}{\partial t}(s, t) \\ &= u_x(\gamma(s, t)) \cdot \frac{\partial \beta_1}{\partial t}(s, t) + u_y(\gamma(s, t)) \cdot \frac{\partial \beta_2}{\partial t}(s, t) \\ &\quad \text{by definition of } \gamma \\ &= u_x(\gamma(s, t)) \cdot A(\beta(s, t)) + u_y(\gamma(s, t)) \cdot B(\beta(s, t)) \quad \text{by } (*). \quad \spadesuit\end{aligned}$$

We will say that the initial curve σ is **free for the initial condition** $\overset{\circ}{u}$ when it satisfies

$$\sigma_1'(s) \cdot B(\sigma_1(s), \sigma_2(s), \overset{\circ}{u}(s)) \neq \sigma_2'(s) \cdot A(\sigma_1(s), \sigma_2(s), \overset{\circ}{u}(s)).$$

Thus we can solve the Cauchy problem for a quasi-linear PDE (1) for any initial condition along any curve which is free for this initial condition. (In the linear case things are simpler, since the condition that σ be free doesn't depend on the initial condition \mathring{u} .)

The worst way in which the initial curve $\sigma : [a, b] \rightarrow \mathbb{R}^2$ can fail to be free for the initial condition \mathring{u} is when $\sigma'(s) = (\sigma_1'(s), \sigma_2'(s))$ and $(A(\sigma_1(s), \sigma_2(s), \mathring{u}(s)), B(\sigma_1(s), \sigma_2(s), \mathring{u}(s))) = (A(\bullet), B(\bullet))$ are everywhere linearly dependent. In this case, it is customary to say that σ is **characteristic** for \mathring{u} ; this does *not* mean that σ is a characteristic curve (indeed, σ isn't even a curve in \mathbb{R}^3). If we assume that σ is an imbedding, then σ is characteristic if and only if $(A(\bullet), B(\bullet))$ is always a multiple of the tangent vector $\sigma'(s)$; by reparameterizing σ we can then arrange that

$$(A(\bullet), B(\bullet)) = \sigma'(s).$$

Then if \mathring{u} is to be the initial condition for a solution u of (1) we must have

$$\begin{aligned} C(\bullet) &= \sigma_1'(s) \cdot u_x(\sigma(s)) + \sigma_2'(s) \cdot u_y(\sigma(s)) \\ &= \frac{d}{ds} u(\sigma(s)) = \frac{d}{ds} \mathring{u}(s). \end{aligned}$$

These equations show that the reparameterized curve $s \mapsto (\sigma_1(s), \sigma_2(s), \mathring{u}(s))$ must be a characteristic curve; equivalently, the original curve $s \mapsto (\sigma_1(s), \sigma_2(s), \mathring{u}(s))$ must be a characteristic curve up to reparameterization in order for the Cauchy problem to be solvable when σ is characteristic for \mathring{u} . If our initial condition \mathring{u} does have this property, then there will be infinitely many solutions u with this initial condition along σ . The characteristic curves in \mathbb{R}^3 are the places where the graphs of different solutions intersect; the projections of the characteristic curves onto \mathbb{R}^2 are the places where different solutions agree.

It should be clear once again that a quasi-linear first order PDE has solutions which are less differentiable than its coefficients.

We are now ready to consider the most general *first order* PDE

$$(1) \quad F(x, y, u, p, q) = F(x, y, u(x, y), u_x(x, y), u_y(x, y)) = 0.$$

This equation can also be reduced to a system of ordinary differential equations, but in this case the system will involve *five* functions; the geometric analysis will be correspondingly more complicated.

At each point $(x_0, y_0, z_0) \in \mathbb{R}^3$, we can consider the set of all vectors $(a, b, -1)$ with

$$F(x_0, y_0, z_0, a, b) = 0,$$

and the corresponding family $\mathcal{F}(x_0, y_0, z_0)$ of planes perpendicular to such vectors. If u is a solution of (1), and M_u is the surface $M_u = \{(x, y, u(x, y))\}$,

then the tangent space of M_u at $(x_0, y_0, u(x_0, y_0))$ is a member of the family $\mathcal{F}(x_0, y_0, u(x_0, y_0))$. In order to describe this situation more geometrically, we would like to have a more geometric way of describing the families $\mathcal{F}(x_0, y_0, z_0)$. Now the relation

$$F(x_0, y_0, z_0, a, b) = 0$$

is one equation in the two unknowns, a and b , so $\mathcal{F}(x_0, y_0, z_0)$ ought to be a one-parameter family of planes; this suggests that there is a cone $K(x_0, y_0, z_0)$, having its vertex at (x_0, y_0, z_0) , with the property that a plane P is in $\mathcal{F}(x_0, y_0, z_0)$ if and only if P is tangent to $K(x_0, y_0, z_0)$ along a generator of this cone. If we

consider a quasi-linear equation

$$F(x, y, u, p, q) = A(x, y, u) \cdot p + B(x, y, u) \cdot q - C(x, y, u) = 0,$$

we immediately see that this is not always so. For in this case, the family $\mathcal{F}(x_0, y_0, z_0)$ consists of planes perpendicular to vectors $(a, b, -1)$ with

$$a \cdot A(x_0, y_0, z_0) + b \cdot B(x_0, y_0, z_0) = C(x_0, y_0, z_0).$$

These planes all contain the characteristic vector

$$(A(x_0, y_0, z_0), B(x_0, y_0, z_0), C(x_0, y_0, z_0)).$$

Thus our “cone” degenerates into a straight line through (x_0, y_0, z_0) , pointing in the direction of the characteristic vector at that point. Clearly things might

be even messier if the analytic properties of the function F are sufficiently nasty.

Despite these difficulties, we can obtain a great deal of geometric motivation by temporarily pretending that each family $\mathcal{F}(x_0, y_0, z_0)$ is determined by a cone $K(x_0, y_0, z_0)$, which happens to degenerate to a straight line in the case of a quasi-linear equation. This semi-mythical cone is called the **Monge cone** at (x_0, y_0, z_0) . Having accepted this fiction, we can now imagine a field of cones in \mathbb{R}^3 ; a C^1 function $u: \mathbb{R}^2 \rightarrow \mathbb{R}$ is a solution of equation (1) if and only

if the corresponding surface $M_u = \{(x, y, u(x, y))\}$ is tangent to the Monge cone $K(x_0, y_0, u(x_0, y_0))$ at each point $(x_0, y_0, u(x_0, y_0))$. This gives us a field of directions at each point of M_u , namely the direction which lies along a generator of the Monge cone at that point. The integral manifolds of this field of directions could be called the “characteristic curves of the solution u ”. This definition is easily seen to be compatible with the one already given in

the quasi-linear case, where the Monge cones degenerate to straight lines. For, these straight lines must be the field of directions for any solution u , and the “characteristic curves of the solution u ” are simply those characteristic curves of the quasi-linear equation which happen to lie on M_u . But in the general case, we cannot write \mathbb{R}^3 as a disjoint union of curves in such a way that each M_u is the union of a certain subset of these curves; we cannot describe the “characteristic curves of a solution u ” at all until we already know u . This might make the concept seem rather useless, but the requisite supplementary considerations will appear quite naturally when we seek an analytic description of these geometric pictures.

How would we go about finding an analytic description of the Monge cone? The Addendum to Chapter 3 suggests that the Monge cone $K(x_0, y_0, z_0)$ should be the “envelope” of the family of planes $\mathcal{F}(x_0, y_0, z_0)$; geometrically, the generators of $K(x_0, y_0, z_0)$ should be the limits of the intersections of two planes of the family $\mathcal{F}(x_0, y_0, z_0)$, the limit being formed as the two planes approach each other. Until we explicitly say the opposite, everything we now do will be based on the assumption that these limits really exist; the ensuing discussion is consequently merely a route to discovery, and does not purport to prove anything.

Let us assume for the moment that the equation

$$F(x_0, y_0, z_0, a, b) = 0$$

can be solved for b in terms of a . In other words, assume there is a function ϕ with

$$(i) \quad F(x_0, y_0, z_0, a, \phi(a)) = 0.$$

One plane of the family $\mathcal{F}(x_0, y_0, z_0)$ may be described by the equation

$$z - z_0 = a(x - x_0) + \phi(a)(y - y_0).$$

A nearby plane may be described by the equation

$$z - z_0 = (a + h)(x - x_0) + \phi(a + h)(y - y_0).$$

The points (x, y, z) in the intersection then satisfy

$$0 = h(x - x_0) + [\phi(a + h) - \phi(a)](y - y_0),$$

and hence

$$0 = (x - x_0) + \left[\frac{\phi(a + h) - \phi(a)}{h} \right] (y - y_0).$$

Therefore points in the limiting intersection ought to satisfy

$$(ii) \quad \begin{cases} z - z_0 = a(x - x_0) + \phi(a)(y - y_0) \\ 0 = (x - x_0) + \phi'(a)(y - y_0). \end{cases}$$

On the other hand, equation (i) shows that

$$\begin{aligned} 0 &= \frac{d}{da} F(x_0, y_0, z_0, a, \phi(a)) \\ &= F_p(x_0, y_0, z_0, a, \phi(a)) + \phi'(a) \cdot F_q(x_0, y_0, z_0, a, \phi(a)), \end{aligned}$$

and hence

$$(iii) \quad \phi'(a) = - \frac{F_p(x_0, y_0, z_0, a, \phi(a))}{F_q(x_0, y_0, z_0, a, \phi(a))}.$$

From (ii) and (iii) we find that the points (x, y, z) on the Monge cone $K(x_0, y_0, z_0)$ should satisfy

$$(iv) \quad \begin{cases} z - z_0 = a(x - x_0) + b(y - y_0), & \text{where } a \text{ and } b \text{ are} \\ & \text{numbers such that:} \\ F(x_0, y_0, z_0, a, b) = 0 \\ \frac{x - x_0}{F_p} = \frac{y - y_0}{F_q} & [F_p \text{ and } F_q \text{ evaluated at } (x_0, y_0, z_0, a, b)]. \end{cases}$$

Now consider a solution u of (I), and let

$$z_0 = u(x_0, y_0), \quad p_0 = u_x(x_0, y_0), \quad q_0 = u_y(x_0, y_0).$$

The tangent plane of M_u at (x_0, y_0, z_0) consists of points (x, y, z) satisfying

$$z - z_0 = p_0(x - x_0) + q_0(y - y_0).$$

Equations (iv) show that points (x, y, z) which are on both this tangent plane and the Monge cone $K(x_0, y_0, z_0)$ ought to satisfy

$$(v) \quad \frac{x - x_0}{F_p} = \frac{y - y_0}{F_q} = \frac{z - z_0}{p_0 F_p + q_0 F_q}$$

$[F_p \text{ and } F_q \text{ evaluated at } (x_0, y_0, z_0, p_0, q_0)].$

Therefore, these points ought to lie along the line through (x_0, y_0, z_0) with direction

$$(F_p, F_q, p_0 F_p + q_0 F_q) \quad [F_p \text{ and } F_q \text{ evaluated at } (x_0, y_0, z_0, p_0, q_0)].$$

We have finally reached the stage where we can make a perfectly sensible definition, involving no assumptions at all. Let u be a solution of (1), and for a point (x_0, y_0) , define z_0 , p_0 , and q_0 as before. We then define the **characteristic vector of u at (x_0, y_0)** to be the vector

$$(2) \quad X(u; x_0, y_0) = (F_p, F_q, p_0 F_p + q_0 F_q),$$

where F_p and F_q are to be evaluated at $(x_0, y_0, z_0, p_0, q_0)$; this vector is to be considered as an element of $\mathbb{R}^3_{(x_0, y_0, z_0)}$. If $M_u = \{(x, y, u(x, y))\}$, then the tangent plane of M_u at (x_0, y_0, z_0) is perpendicular to the vector $(p_0, q_0, -1)$. The vector $X(u; x_0, y_0)$ clearly has this property, so every characteristic vector of u is tangent to M_u , and the set of all characteristic vectors of u forms a vector field on M_u . The integral curves of this vector field are called the **characteristic curves of the solution u** , and they are clearly curves on M_u .

A characteristic curve c of u is thus a curve in \mathbb{R}^3 satisfying the equations

$$(3) \quad \begin{cases} \frac{dc_1(t)}{dt} = F_p(\bullet) \\ \frac{dc_2(t)}{dt} = F_q(\bullet) \\ \frac{dc_3(t)}{dt} = u_x(c_1(t), c_2(t)) \cdot F_p(\bullet) + u_y(c_1(t), c_2(t)) \cdot F_q(\bullet) \\ \text{where } \bullet = (c_1(t), c_2(t), c_3(t), u_x(c_1(t), c_2(t)), u_y(c_1(t), c_2(t))). \end{cases}$$

Now if we assume that u is C^2 , then we can also obtain equations for the partials $u_x(c_1(t), c_2(t))$ and $u_y(c_1(t), c_2(t))$. For equations (3) allow us to write

$$(4) \quad \begin{cases} \frac{du_x(c_1(t), c_2(t))}{dt} = u_{xx}(c_1(t), c_2(t)) \frac{dc_1(t)}{dt} + u_{xy}(c_1(t), c_2(t)) \frac{dc_2(t)}{dt} \\ \quad \quad \quad = u_{xx}(c_1(t), c_2(t)) F_p(\bullet) + u_{xy}(c_1(t), c_2(t)) F_q(\bullet) \\ \frac{du_y(c_1(t), c_2(t))}{dt} = u_{yx}(c_1(t), c_2(t)) F_p(\bullet) + u_{yy}(c_1(t), c_2(t)) F_q(\bullet). \end{cases}$$

On the other hand, since u satisfies

$$F(x, y, u(x, y), u_x(x, y), u_y(x, y)) = 0,$$

we also have

$$(5) \quad \begin{cases} F_x + u_x F_u + u_{xx} F_p + u_{yx} F_q = 0 \\ F_y + u_y F_u + u_{xy} F_p + u_{yy} F_q = 0, \end{cases}$$

where all partials of F are evaluated at $(x, y, u(x, y), u_x(x, y), u_y(x, y))$. Thus equations (4) become

$$(6) \quad \begin{cases} \frac{du_x(c_1(t), c_2(t))}{dt} = -F_x(\bullet) - u_x(c_1(t), c_2(t)) \cdot F_u(\bullet) \\ \frac{du_y(c_1(t), c_2(t))}{dt} = -F_y(\bullet) - u_y(c_1(t), c_2(t)) \cdot F_u(\bullet). \end{cases}$$

Let us now define a curve Γ in \mathbb{R}^5 by

$$(7) \quad \Gamma(t) = (c_1(t), c_2(t), c_3(t), u_x(c_1(t), c_2(t)), u_y(c_1(t), c_2(t))).$$

Then equations (3) and (6) may be written

$$(8) \quad \begin{cases} \frac{d\Gamma_1(t)}{dt} = F_p(\Gamma(t)) \\ \frac{d\Gamma_2(t)}{dt} = F_q(\Gamma(t)) \\ \frac{d\Gamma_3(t)}{dt} = \Gamma_4(t) \cdot F_p(\Gamma(t)) + \Gamma_5(t) \cdot F_q(\Gamma(t)) \\ \frac{d\Gamma_4(t)}{dt} = -F_x(\Gamma(t)) - \Gamma_4(t) \cdot F_u(\Gamma(t)) \\ \frac{d\Gamma_5(t)}{dt} = -F_y(\Gamma(t)) - \Gamma_5(t) \cdot F_u(\Gamma(t)). \end{cases}$$

Now although the curve Γ was defined in terms of a solution u , the final equations (8) involve *only* the original equation (1). This will allow us to define geometrically meaningful objects which do not depend on knowing a solution u . We may regard a point $(x_0, y_0, z_0, a, b) \in \mathbb{R}^5$ as a plane in the tangent space $\mathbb{R}^3_{(x_0, y_0, z_0)}$, namely, as the plane perpendicular to the vector $(a, b, -1)$. A curve Γ in \mathbb{R}^5 may then be regarded as a family of planes, the plane at time t being in the tangent space of \mathbb{R}^3 at $c(t) = (\Gamma_1(t), \Gamma_2(t), \Gamma_3(t))$; it will be convenient to refer to this curve c as the **base curve** of Γ . An arbitrary curve Γ is called

a **strip** if the tangent vector $c'(t)$ of the base curve c always lies in the plane determined by Γ at time t . This means that

$$c'(t) = (\Gamma_1'(t), \Gamma_2'(t), \Gamma_3'(t)) \text{ is perpendicular to } (\Gamma_4(t), \Gamma_5(t), -1).$$

So Γ is a strip if and only if it satisfies the **strip condition**:

$$(9) \quad \frac{d\Gamma_3(t)}{dt} = \Gamma_4(t) \frac{d\Gamma_1(t)}{dt} + \Gamma_5(t) \frac{d\Gamma_2(t)}{dt}.$$

Notice that any solution of (8) is automatically a strip. A curve Γ will be called a **characteristic strip** of the PDE (1) if Γ satisfies (8) and also

$$(10) \quad F(\Gamma(t)) = F(\Gamma_1(t), \Gamma_2(t), \Gamma_3(t), \Gamma_4(t), \Gamma_5(t)) = 0.$$

This last restriction is not as stringent as it might first seem, for if Γ satisfies (8), then

$$\begin{aligned} (11) \quad \frac{d}{dt} F(\Gamma(t)) &= F_x \frac{d\Gamma_1(t)}{dt} + \cdots + F_q \frac{d\Gamma_5(t)}{dt} \\ &\quad [\text{all partials of } F \text{ evaluated at } \Gamma(t)] \\ &= F_x F_p + F_y F_q + F_z \cdot (\Gamma_4(t) F_p + \Gamma_5(t) F_q) \\ &\quad + F_p \cdot (-F_x - \Gamma_4(t) F_z) + F_q \cdot (-F_y - \Gamma_5(t) F_z) \\ &= 0. \end{aligned}$$

So if Γ satisfies (8) and also satisfies (10) for one t , then it satisfies (10) for all t , and is consequently a characteristic strip.

Now how are characteristic strips related to solutions? We have seen that if u is a solution of (1), then M_u is the union of certain characteristic curves [solutions of (3)]. Moreover, if c is a characteristic curve, then the set of tangent planes of M_u along c gives the curve Γ of equation (7), which is a characteristic strip. So M_u is the union of base curves of characteristic strips.

Now suppose that we have an arbitrary curve Σ in \mathbb{R}^5 , with base curve σ , and that $F(\Sigma(s)) = 0$ for all s . There is a unique solution of (8) through each point $\Sigma(s)$, and by the remark after equation (11), this solution is a characteristic strip. We thus obtain a family of characteristic strips Γ . The union of the corresponding base curves c is a surface M_u , containing the base curve σ . Is it reasonable to suppose now that u is a solution of (1)? The answer is no, for there is clearly no hope unless Σ is also a strip. When this condition is satisfied, then everything works out. We will prove that if $\sigma: [a, b] \rightarrow \mathbb{R}^2$ is a given

curve, $\hat{u}: [a, b] \rightarrow \mathbb{R}$ is a given function, and $\hat{p}, \hat{q}: [a, b] \rightarrow \mathbb{R}$ are two functions satisfying

$$(a) \quad F(\Sigma(s)) = F(\sigma_1(s), \sigma_2(s), \hat{u}(s), \hat{p}(s), \hat{q}(s)) = 0,$$

and the strip condition

$$(b) \quad \frac{d\hat{u}(s)}{ds} = \hat{p}(s) \frac{d\sigma_1(s)}{ds} + \hat{q}(s) \frac{d\sigma_2(s)}{ds},$$

then there is a unique solution u of (1) satisfying

$$u(\sigma(s)) = \hat{u}(s), \quad u_x(\sigma(s)) = \hat{p}(s), \quad u_y(\sigma(s)) = \hat{q}(s)$$

[naturally, (b) is a necessary consequence of these equations]. We will clearly have to assume that $\sigma'(s)$ is linearly independent of the vector obtained by projecting the characteristic vector (2) on the (x, y) -plane. In other words, we will have to require that $\sigma'(s)$ and $(F_p(\Sigma(s)), F_q(\Sigma(s)))$ are linearly independent, or that

$$(c) \quad \sigma_1'(s) \cdot F_q(\Sigma(s)) \neq \sigma_2'(s) \cdot F_p(\Sigma(s)).$$

Before we proceed to prove the theorem, we should insert a remark about the hypotheses, which will involve σ , \hat{u} , \hat{p} , and \hat{q} satisfying (a)–(c). At first sight, we seem to be contradicting our basic philosophy about first order equations, for we seem to be saying that we can arbitrarily specify not only the values \hat{u} of u

along σ , but *also* the values $\overset{\circ}{p}$ and $\overset{\circ}{q}$ of u_x and u_y along σ . This is not really the case, for $\overset{\circ}{p}$ and $\overset{\circ}{q}$ are practically determined by the equations (a) and (b) which they must satisfy. This is most apparent when our initial curve σ is the x -axis, $\sigma(s) = (s, 0)$. Then equation (b) already determines $\overset{\circ}{p}$. Moreover, condition (c) says that $F_q \neq 0$ along $\{(s, 0, \overset{\circ}{u}(s), \overset{\circ}{p}(s), \overset{\circ}{q}(s))\}$, so the implicit function theorem shows that equation (a) can be solved for $\overset{\circ}{q}(s)$ in terms of $\overset{\circ}{p}(s)$ —there is a function ϕ with

$$F(s, 0, \overset{\circ}{u}(s), \overset{\circ}{p}(s), \phi(\overset{\circ}{p}(s))) = 0.$$

Of course, there may be several possible ϕ , but once $\overset{\circ}{q}(0)$ is determined, there will be only one continuous choice of $\overset{\circ}{q}$ satisfying (a). [In the quasi-linear case, $\overset{\circ}{q}(s)$ will actually be uniquely determined.] It is not hard to see that a similar situation prevails when σ is any curve satisfying (c): we are essentially specifying only the values $\overset{\circ}{u}$ of u along σ , and then making certain that we have a continuous choice of the limited possibilities for $\overset{\circ}{p}$ and $\overset{\circ}{q}$. In order to emphasize this point we will refer to $(\overset{\circ}{u}, \overset{\circ}{p}, \overset{\circ}{q})$ as “initial data”, rather than as initial conditions.

3. THEOREM. Let F be a function of class C^k , $k \geq 3$, defined in an open set $U \subset \mathbb{R}^5$. Let $\sigma: [a, b] \rightarrow \mathbb{R}^2$ be a one-one C^{k-1} function, and let $\overset{\circ}{u}, \overset{\circ}{p}, \overset{\circ}{q}: [a, b] \rightarrow \mathbb{R}$ be C^{k-1} functions such that for all $s \in [a, b]$ we have

$$(a) \quad \Sigma(s) = (\sigma_1(s), \sigma_2(s), \overset{\circ}{u}(s), \overset{\circ}{p}(s), \overset{\circ}{q}(s)) \in U \quad \text{and} \quad F(\Sigma(s)) = 0,$$

$$(b) \quad \frac{d\overset{\circ}{u}(s)}{ds} = \overset{\circ}{p}(s) \frac{d\sigma_1(s)}{ds} + \overset{\circ}{q}(s) \frac{d\sigma_2(s)}{ds},$$

$$(c) \quad \sigma_1'(s) \cdot F_q(\Sigma(s)) \neq \sigma_2'(s) \cdot F_p(\Sigma(s)).$$

Then there is a C^{k-1} function u , defined in a neighborhood V of $\sigma([a, b])$, which satisfies the equation

$$F(x, y, u(x, y), u_x(x, y), u_y(x, y)) = 0 \quad \text{on } V$$

and also

$$u(\sigma(s)) = \overset{\circ}{u}(s), \quad u_x(\sigma(s)) = \overset{\circ}{p}(s), \quad u_y(\sigma(s)) = \overset{\circ}{q}(s), \quad \text{for } s \in [a, b].$$

Moreover, any two functions u with this property agree on a neighborhood of $\sigma([a, b])$.

PROOF. As in the proof of Theorems 1 and 2, we use Problem I.5-5 to conclude that there is a C^{k-1} function $\alpha = (\alpha_1, \dots, \alpha_5)$ with

$$(*) \quad \begin{cases} \alpha(0, s, r) = r & \text{for } r \in \mathbb{R}^5 \\ \frac{\partial}{\partial t} \alpha_1(t, s, r) = F_p(\alpha(t, s, r)) \\ \frac{\partial}{\partial t} \alpha_2(t, s, r) = F_q(\alpha(t, s, r)) \\ \frac{\partial}{\partial t} \alpha_3(t, s, r) = \alpha_4(t, s, r) \cdot F_p(\alpha(t, s, r)) + \alpha_5(t, s, r) \cdot F_q(\alpha(t, s, r)) \\ \frac{\partial}{\partial t} \alpha_4(t, s, r) = -F_x(\alpha(t, s, r)) - \alpha_4(t, s, r) \cdot F_u(\alpha(t, s, r)) \\ \frac{\partial}{\partial t} \alpha_5(t, s, r) = -F_y(\alpha(t, s, r)) - \alpha_5(t, s, r) \cdot F_u(\alpha(t, s, r)). \end{cases}$$

Let

$$\beta(s, t) = \alpha(t, s, \sigma_1(s), \sigma_2(s), \dot{u}(s), \dot{p}(s), \dot{q}(s)),$$

so that β is also C^{k-1} . In particular,

$$\beta(s, 0) = (\sigma_1(s), \sigma_2(s), \dot{u}(s), \dot{p}(s), \dot{q}(s)) = \Sigma(s).$$

If we define

$$\gamma(s, t) = (\beta_1(s, t), \beta_2(s, t)) \in \mathbb{R}^2,$$

then the Jacobian of γ at $(s, 0)$ is

$$\begin{aligned} \begin{pmatrix} \frac{\partial \beta_1}{\partial s}(s, 0) & \frac{\partial \beta_1}{\partial t}(s, 0) \\ \frac{\partial \beta_2}{\partial s}(s, 0) & \frac{\partial \beta_2}{\partial t}(s, 0) \end{pmatrix} &= \begin{pmatrix} \sigma_1'(s) & \frac{\partial \alpha_1}{\partial t}(0, s, \Sigma(s)) \\ \sigma_2'(s) & \frac{\partial \alpha_2}{\partial t}(0, s, \Sigma(s)) \end{pmatrix} \\ &= \begin{pmatrix} \sigma_1'(s) & F_p(\Sigma(s)) \\ \sigma_2'(s) & F_q(\Sigma(s)) \end{pmatrix} \quad \text{by } (*), \end{aligned}$$

and this is non-singular by hypothesis. So if ε is sufficiently small, then $\gamma: [a, b] \times (-\varepsilon, \varepsilon) \rightarrow \mathbb{R}^2$ is a C^{k-1} diffeomorphism onto a neighborhood V of $\sigma([a, b])$.

The solution u , if it exists, clearly must be the C^{k-1} function

$$u(x, y) = \beta_3(\gamma^{-1}(x, y)) \quad \text{or equivalently} \quad u(\gamma(s, t)) = \beta_3(s, t).$$

We claim that

$$u_x(\gamma(s, t)) = \beta_4(s, t) \quad \text{and} \quad u_y(\gamma(s, t)) = \beta_5(s, t).$$

This will prove that

$$F(x, y, u(x, y), u_x(x, y), u_y(x, y)) = 0;$$

for we have already seen (equation 11) that $F(\alpha(t, s, r))$ is constant for fixed s and r , while $F(\alpha(0, s, \Sigma(s))) = 0$ by (a), so that we will have

$$\begin{aligned} 0 &= F(\alpha(t, s, \Sigma(s))) = F(\beta(s, t)) = F(\beta_1(s, t), \beta_2(s, t), \beta_3(s, t), \beta_4(s, t), \beta_5(s, t)) \\ &= F(\gamma(s, t), u(\gamma(s, t)), u_x(\gamma(s, t)), u_y(\gamma(s, t))). \end{aligned}$$

To prove the claim, we consider the function

$$\Delta = \frac{\partial \beta_3}{\partial s} - \beta_4 \cdot \frac{\partial \beta_1}{\partial s} - \beta_5 \cdot \frac{\partial \beta_2}{\partial s}.$$

We have

$$\begin{aligned} \Delta(s, 0) &= \frac{d\mathring{u}(s)}{ds} - \mathring{p}(s) \cdot \frac{d\sigma_1(s)}{ds} - \mathring{q}(s) \cdot \frac{d\sigma_2(s)}{ds} \\ &= 0 \quad \text{by (b).} \end{aligned}$$

Moreover,

$$\begin{aligned} \frac{\partial \Delta}{\partial t} &= \frac{\partial^2 \beta_3}{\partial s \partial t} - \frac{\partial \beta_4}{\partial t} \frac{\partial \beta_1}{\partial s} - \frac{\partial \beta_5}{\partial t} \frac{\partial \beta_2}{\partial s} - \beta_4 \cdot \frac{\partial^2 \beta_1}{\partial s \partial t} - \beta_5 \cdot \frac{\partial^2 \beta_2}{\partial s \partial t} \\ &= \frac{\partial}{\partial s} \left(\frac{\partial \beta_3}{\partial t} - \beta_4 \cdot \frac{\partial \beta_1}{\partial t} - \beta_5 \cdot \frac{\partial \beta_2}{\partial t} \right) \\ &\quad + \frac{\partial \beta_4}{\partial s} \frac{\partial \beta_1}{\partial t} + \frac{\partial \beta_5}{\partial s} \frac{\partial \beta_2}{\partial t} - \frac{\partial \beta_4}{\partial t} \frac{\partial \beta_1}{\partial s} - \frac{\partial \beta_5}{\partial t} \frac{\partial \beta_2}{\partial s} \\ &= 0 + F_p \cdot \frac{\partial \beta_4}{\partial s} + F_q \cdot \frac{\partial \beta_5}{\partial s} + (F_x + F_u \beta_4) \frac{\partial \beta_1}{\partial s} + (F_y + F_u \beta_5) \frac{\partial \beta_2}{\partial s} \\ &\quad \text{by (*)} \quad [\text{where all partials of } F \text{ are evaluated at } \beta(s, t)] \\ &= F_x \cdot \frac{\partial \beta_1}{\partial s} + F_y \cdot \frac{\partial \beta_2}{\partial s} + F_u \cdot \frac{\partial \beta_3}{\partial s} + F_p \cdot \frac{\partial \beta_4}{\partial s} + F_q \cdot \frac{\partial \beta_5}{\partial s} \\ &\quad - F_u \cdot \left(\frac{\partial \beta_3}{\partial s} - \beta_4 \cdot \frac{\partial \beta_1}{\partial s} - \beta_5 \cdot \frac{\partial \beta_2}{\partial s} \right) \\ &= \frac{\partial}{\partial s} (F(\beta(s, t))) - F_u \cdot \Delta \\ &= -F_u \cdot \Delta, \end{aligned}$$

since we have already seen that $F(\beta(s, t)) = 0$. Now for each fixed s , we have an ordinary differential equation

$$\frac{\partial \Delta}{\partial t} = -F_u \cdot \Delta,$$

with the initial condition

$$\Delta(s, 0) = 0,$$

so the unique solution is $\Delta(s, t) = 0$. In other words, we have shown that

$$\frac{\partial \beta_3}{\partial s} = \beta_4 \cdot \frac{\partial \beta_1}{\partial s} + \beta_5 \cdot \frac{\partial \beta_2}{\partial s}.$$

Also

$$\frac{\partial \beta_3}{\partial t} = \beta_4 \cdot \frac{\partial \beta_1}{\partial t} + \beta_5 \cdot \frac{\partial \beta_2}{\partial t} \quad \text{by } (*).$$

On the other hand, differentiating the definition $u(\gamma(s, t)) = \beta_3(s, t)$ gives

$$\begin{aligned} \frac{\partial \beta_3}{\partial s} &= u_x(\gamma(s, t)) \cdot \frac{\partial \beta_1}{\partial s} + u_y(\gamma(s, t)) \cdot \frac{\partial \beta_2}{\partial s} \\ \frac{\partial \beta_3}{\partial t} &= u_x(\gamma(s, t)) \cdot \frac{\partial \beta_1}{\partial t} + u_y(\gamma(s, t)) \cdot \frac{\partial \beta_2}{\partial t}. \end{aligned}$$

These last four equations give two solutions for two linear equations in two unknowns, whose determinant

$$\det \begin{pmatrix} \frac{\partial \beta_1}{\partial s} & \frac{\partial \beta_2}{\partial s} \\ \frac{\partial \beta_1}{\partial t} & \frac{\partial \beta_2}{\partial t} \end{pmatrix}$$

is $\neq 0$ for $(s, t) \in [a, b] \times (-\varepsilon, \varepsilon)$. So the two solutions must be the same, i.e.,

$$u_x(\gamma(s, t)) = \beta_4(s, t) \quad \text{and} \quad u_y(\gamma(s, t)) = \beta_5(s, t),$$

as desired. ♦

We will say that the initial curve σ is **free for the initial data** $\overset{\circ}{u}, \overset{\circ}{p}, \overset{\circ}{q}$ when condition (c) in Theorem 3 is satisfied. Thus we can solve the Cauchy problem for a first order PDE (I) for any initial strip $\Sigma = (\sigma_1, \sigma_2, \overset{\circ}{u}, \overset{\circ}{p}, \overset{\circ}{q})$ for which the initial curve σ is free for the initial data $\overset{\circ}{u}, \overset{\circ}{p}, \overset{\circ}{q}$.

Again we consider the case where our initial curve σ fails to be free for the initial data $\overset{\circ}{u}, \overset{\circ}{p}, \overset{\circ}{q}$ in the worst possible way, namely when $\sigma'(s)$ and $(F_p(\Sigma(s)), F_q(\Sigma(s)))$ are everywhere linearly dependent. Once again we say that σ is **characteristic** for $\overset{\circ}{u}, \overset{\circ}{p}, \overset{\circ}{q}$. Assuming that σ is an imbedding, we can reparameterize σ so that $\sigma'(s) = (F_p(\Sigma(s)), F_q(\Sigma(s)))$. This gives us the first two equations in (8) for the curve $(\sigma_1, \sigma_2, \overset{\circ}{u}, \overset{\circ}{p}, \overset{\circ}{q})$. The third equation of (8) is just the strip condition (b). The argument on pages 18–19 shows that these three equations imply the last two if there is a solution u of (I) with

$$u(\sigma(s)) = \overset{\circ}{u}(s), \quad u_x(\sigma(s)) = \overset{\circ}{p}(s), \quad u_y(\sigma(s)) = \overset{\circ}{q}(s).$$

So when σ is characteristic, the Cauchy problem is solvable for the initial data $\overset{\circ}{u}, \overset{\circ}{p}, \overset{\circ}{q}$ along σ only if $(\sigma_1, \sigma_2, \overset{\circ}{u}, \overset{\circ}{p}, \overset{\circ}{q})$ is a characteristic strip. When this is the case, there will be infinitely many solutions with this initial data along σ . The base curves of characteristic strips are the intersection curves of the graphs of different solutions meeting tangentially.

We can now describe the situation for first order PDE's in n variables very easily, without bothering to write down all the results as formal theorems. Consider first the quasi-linear PDE

$$\sum_{i=1}^n A_i(x_1, \dots, x_n, u) \cdot u_{x_i} = C(x_1, \dots, x_n, u).$$

The **characteristic vector field** of this equation is the vector field X in \mathbb{R}^{n+1} defined by

$$X = \sum_{i=1}^n A_i \frac{\partial}{\partial x_i} + C \frac{\partial}{\partial z};$$

the integral curves of X are the **characteristic curves** of the equation. As in the case $n = 2$, it is clear that if u is a solution of (I), then the hypersurface

$$M_u = \{(x_1, \dots, x_n, u(x_1, \dots, x_n))\} \subset \mathbb{R}^{n+1}$$

is a union of characteristic curves. Now suppose we are given a one-one map

$$\sigma: \mathcal{D} \rightarrow \mathbb{R}^n,$$

where $\mathcal{D} \subset \mathbb{R}^{n-1}$ is a compact $(n-1)$ -dimensional manifold-with-boundary, and a function $\overset{\circ}{u}: \mathcal{D} \rightarrow \mathbb{R}$. We can produce a solution u of (I) with

$$u(\sigma(s)) = \overset{\circ}{u}(s) \quad \text{for all } s \in \mathcal{D}$$

by taking the union of the characteristic curves through all points $(\sigma(s), \mathring{u}(s)) \in \mathbb{R}^{n+1}$. The proof is exactly analogous to the proof of Theorem 2, except that we will now require that the matrix

$$\begin{pmatrix} D_1\sigma_1(s) & \dots & D_{n-1}\sigma_1(s) & A_1(\sigma(s), \mathring{u}(s)) \\ \vdots & & \vdots & \vdots \\ D_1\sigma_n(s) & \dots & D_{n-1}\sigma_n(s) & A_n(\sigma(s), \mathring{u}(s)) \end{pmatrix}$$

be non-singular for all $s \in \mathcal{D}$. This means, first of all, that the matrix $(D_j\sigma_i(s))$ must have rank $n - 1$, so that σ is an imbedding and $\sigma(\mathcal{D}) \subset \mathbb{R}^n$ is a hypersurface. In addition, the vector $(A_1(\sigma(s), \mathring{u}(s)), \dots, A_n(\sigma(s), \mathring{u}(s)))$ must not lie in the tangent space of $\sigma(\mathcal{D})$; we express this by saying that the “initial manifold” $\sigma(\mathcal{D})$ is **free for the initial condition** \mathring{u} (for linear equations the initial condition \mathring{u} is irrelevant). Thus we can solve the Cauchy problem for any initial condition along an initial $(n - 1)$ -manifold which is free for the initial condition.

Now we consider the general first order PDE

$$F(x_1, \dots, x_n, u(x_1, \dots, x_n), u_{x_1}(x_1, \dots, x_n), \dots, u_{x_n}(x_1, \dots, x_n)) = 0.$$

We denote the partials of F by

$$F_{x_i}, \quad F_u, \quad F_{p_i}.$$

Consider curves Γ in \mathbb{R}^{2n+1} satisfying

$$\begin{cases} \frac{d\Gamma_i(t)}{dt} = F_{p_i}(\Gamma(t)) & i = 1, \dots, n \\ \frac{d\Gamma_{n+1}(t)}{dt} = \sum_{i=1}^n \Gamma_{n+1+i}(t) \cdot F_{p_i}(\Gamma(t)) \\ \frac{d\Gamma_{n+1+i}(t)}{dt} = -F_{x_i}(\Gamma(t)) - \Gamma_{n+1+i}(t) F_u(\Gamma(t)) & i = 1, \dots, n. \end{cases}$$

As before, we easily check that if Γ satisfies these equations, then $F(\Gamma(t))$ is constant in t . A solution Γ with $F(\Gamma(t)) = 0$ for all t is called a **characteristic strip**. Now suppose we have a one-one map

$$\sigma: \mathcal{D} \rightarrow \mathbb{R}^n$$

with $\mathcal{D} \subset \mathbb{R}^{n-1}$ as before, and functions

$$\mathring{u}, \mathring{p}_1, \dots, \mathring{p}_n: \mathcal{D} \rightarrow \mathbb{R}$$

with

$$F(\Sigma(s)) = F(\sigma_1(s), \dots, \sigma_n(s), \overset{\circ}{u}(s), \overset{\circ}{p}_1(s), \dots, \overset{\circ}{p}_n(s)) = 0 \quad \text{for all } s \in \mathcal{D}.$$

Then there is a unique characteristic strip Γ through each point $\Sigma(s)$, and the union of the corresponding base curves is a hypersurface M_u . In order for the function u to be a solution to our PDE we will need two conditions, which allow us to extend the proof of Theorem 3 essentially without change. First, the matrix

$$\begin{pmatrix} D_1\sigma_1(s) & \dots & D_{n-1}\sigma_1(s) & F_{p_1}(\Sigma(s)) \\ \vdots & & \vdots & \vdots \\ D_1\sigma_n(s) & \dots & D_{n-1}\sigma_n(s) & F_{p_n}(\Sigma(s)) \end{pmatrix}$$

must be non-singular. Thus $\sigma(\mathcal{D}) \subset \mathbb{R}^n$ must be an $(n-1)$ -manifold, and $(F_{p_1}(\Sigma(s)), \dots, F_{p_n}(\Sigma(s)))$ must not lie in its tangent space—once again, we express this by saying that the initial manifold $\sigma(\mathcal{D})$ is **free for the initial data** $\overset{\circ}{u}, \overset{\circ}{p}_1, \dots, \overset{\circ}{p}_n$. Second, we must have

$$\frac{\partial \overset{\circ}{u}}{\partial s_j} = \sum_{i=1}^n \overset{\circ}{p}_i \cdot \frac{\partial \sigma_i}{\partial s_j}.$$

In terms of Σ , this condition reads

$$\frac{\partial \Sigma_{n+1}}{\partial s_j} = \sum_{i=1}^n \Sigma_{n+1+i} \cdot \frac{\partial \Sigma_i}{\partial s_j},$$

and is called the **strip manifold condition**. If we think of a point $(x_1, \dots, x_n, z, p_1, \dots, p_n)$ in \mathbb{R}^{2n+1} as a hyperplane in $\mathbb{R}^{n+1}_{(x_1, \dots, x_n, z)}$, namely as the hyperplane perpendicular to the vector $(p_1, \dots, p_n, -1)$, then $\Sigma: \mathcal{D} \rightarrow \mathbb{R}^{2n+1}$ may be regarded as a family of hyperplanes along the $(n-1)$ -dimensional submanifold $\sigma(\mathcal{D})$. It is easy to see that Σ satisfies the strip manifold condition if and only if the tangent space of $\sigma(\mathcal{D})$ at any point $\sigma(s)$ always lies in the hyperplane determined by Σ at s . We may summarize by saying that we can solve the Cauchy problem for any strip manifold $(\sigma_1, \dots, \sigma_n, \overset{\circ}{u}, \overset{\circ}{p}_1, \dots, \overset{\circ}{p}_n)$ for which the initial $(n-1)$ -dimensional submanifold $\sigma(\mathcal{D})$ is free for the initial data $\overset{\circ}{u}, \overset{\circ}{p}_1, \dots, \overset{\circ}{p}_n$.

2. FREE INITIAL MANIFOLDS FOR HIGHER ORDER EQUATIONS

In the previous section we found that the characteristic curves or characteristic strips for first order equations were the clue to solving them, while the free hypersurfaces were the appropriate initial manifolds for which we could solve the Cauchy problem. For higher order equations things are not nearly so simple, but we can at least decide at the outset what the free initial manifolds ought to be. To do this, we will first consider the special case where the initial manifold is $M = \{x \in \mathbb{R}^n : x_n = 0\} \subset \mathbb{R}^n$.

First a review of the situation for first order equations. For the quasi-linear equation

$$\sum_{i=1}^n A_i(x_1, \dots, x_n, u) \cdot u_{x_i} = C(x_1, \dots, x_n, u),$$

the manifold $M = \{x \in \mathbb{R}^n : x_n = 0\}$ is free for the initial condition $\overset{\circ}{u}$ on M if and only if

$$A_n(x_1, \dots, x_{n-1}, 0, \overset{\circ}{u}(x_1, \dots, x_{n-1})) \neq 0 \quad \text{on } M.$$

If this condition holds, then in a neighborhood of M we can write our equation as an equation for u_{x_n} in terms of u and the other u_{x_i} :

$$\begin{aligned} u_{x_n} &= - \sum_{i=1}^{n-1} \frac{A_i(x_1, \dots, x_n, u)}{A_n(x_1, \dots, x_n, u)} u_{x_i} + \frac{C(x_1, \dots, x_n, u)}{A_n(x_1, \dots, x_n, u)} \\ &= f(x_1, \dots, x_n, u, u_{x_1}, \dots, u_{x_{n-1}}), \end{aligned}$$

where the function f is defined in a neighborhood of all points

$$(x_1, \dots, x_{n-1}, 0, \overset{\circ}{u}(x_1, \dots, x_{n-1}), p_1, \dots, p_{n-1}).$$

On the other hand, if M fails to be free at some point, then our original equation gives us a relationship between the u_{x_i} for $i < n$, which means that there are additional conditions which $\overset{\circ}{u}$ would have to satisfy for a solution to exist.

For the general first order PDE

$$F(x, u(x), u_{x_1}(x), \dots, u_{x_n}(x)) = 0 \quad [x = (x_1, \dots, x_n)],$$

the initial data $\overset{\circ}{u}, \overset{\circ}{p}_1, \dots, \overset{\circ}{p}_n$ must satisfy, using $x_{1\dots n-1}$ as an abbreviation for x_1, \dots, x_{n-1} ,

$$\begin{aligned} (a) \quad 0 &= F(x_{1\dots n-1}, 0, \overset{\circ}{u}(x_{1\dots n-1}), \overset{\circ}{p}_1(x_{1\dots n-1}), \dots, \overset{\circ}{p}_n(x_{1\dots n-1})) \\ &= F(\Sigma(s)) \quad s = (x_1, \dots, x_{n-1}), \end{aligned}$$

as well as the obvious compatibility conditions

$$(b) \quad \frac{\partial \overset{\circ}{u}}{\partial x_j} = \overset{\circ}{p}_j \quad j = 1, \dots, n-1$$

which is what the strip manifold condition on page 28 boils down to in this case; otherwise expressed, the initial value $\overset{\circ}{u}$ of u along M already determines the values of u_{x_i} along M for $i < n$, so the only other initial data that we need is a value $\overset{\circ}{p}_n$ of u_{x_n} along M satisfying (a), when the $\overset{\circ}{p}_j$ for $j < n$ are defined by (b). Now M is free for this initial data if and only if

$$F_{p_n}(\Sigma(s)) \neq 0 \quad \text{on } M.$$

In this case, the implicit function theorem tells us that there is a unique function f defined in a neighborhood of any given

$$\bullet = (x_1, \dots, x_{n-1}, 0, \overset{\circ}{u}(x_1, \dots, x_{n-1}), \overset{\circ}{p}_1(x_1, \dots, x_{n-1}), \dots, \overset{\circ}{p}_{n-1}(x_1, \dots, x_{n-1}))$$

such that

$$\begin{cases} F(x, z, p_1, \dots, p_{n-1}, f(x, z, p_1, \dots, p_{n-1})) = 0 & \text{in this neighborhood} \\ f(\bullet) = \overset{\circ}{p}_n(x_1, \dots, x_{n-1}). \end{cases}$$

So our PDE is equivalent to the equation

$$u_{x_n} = f(x_1, \dots, x_n, u, u_{x_1}, \dots, u_{x_{n-1}})$$

expressing u_{x_n} in terms of u and the other u_{x_i} . On the other hand, if M is not free at some point, so that $F_{p_n}(\Sigma(s_0)) = 0$ for some s_0 , then we generally cannot find any continuous initial data $\overset{\circ}{p}_n$ satisfying (a).

We will now generalize this discussion to decide when $M = \{x \in \mathbb{R}^n : x_n = 0\}$ should be called free for a second order equation. First consider the quasi-linear second order equation

$$(l) \quad \sum_{i,j=1}^n A_{ij} u_{x_i x_j} = C,$$

where the functions A_{ij} and C depend not only on x_1, \dots, x_n , and u , but also on the u_{x_i} . It seems reasonable that the initial conditions for the Cauchy problem should be the values $\overset{\circ}{u}, \overset{\circ}{p}_1, \dots, \overset{\circ}{p}_n$ of u and its first derivatives on M . But, as we have already noted, $\overset{\circ}{u}$ already determines the $\overset{\circ}{p}_i$ for $i < n$. So the initial

conditions for the Cauchy problem* should be the values $\overset{\circ}{u}, \overset{\circ}{p}_n$ of u and u_{x_n} along M . For the PDE (1) we will define M to be **free for the initial conditions** $\overset{\circ}{u}, \overset{\circ}{p}_n$ if (recall that we are using $x_{1\dots n-1}$ as an abbreviation for x_1, \dots, x_{n-1})

$$\begin{aligned} A_{nn}(\Sigma(s)) &= A_{nn}(x_{1\dots n-1}, 0, \overset{\circ}{u}(x_{1\dots n-1}), \overset{\circ}{p}_1(x_{1\dots n-1}), \dots, \overset{\circ}{p}_n(x_{1\dots n-1})) \\ &\neq 0 \quad \text{on } M, \end{aligned}$$

where $\overset{\circ}{p}_i = \partial \overset{\circ}{u} / \partial x_i$ for $i < n$. If this condition holds, then in a neighborhood of any point of M we can write our equation as an equation for $u_{x_n x_n}$ in terms of u , the first partials u_{x_i} , and the other second partials $u_{x_i x_j}$:

$$\begin{aligned} u_{x_n x_n} &= - \sum_{\substack{i,j=1 \\ (i,j) \neq (n,n)}}^n \frac{A_{ij}}{A_{nn}} u_{x_i x_j} + \frac{C}{A_{nn}} \\ &= f(x_1, \dots, x_n, u, u_{x_1}, \dots, u_{x_n}, \dots, u_{x_i x_j}, \dots), \\ &\quad [(i, j) \neq (n, n)] \end{aligned}$$

where the function f is defined in a neighborhood of all points

$$(x_{1\dots n-1}, 0, \overset{\circ}{u}(x_{1\dots n-1}), \overset{\circ}{p}_1(x_{1\dots n-1}), \dots, \overset{\circ}{p}_n(x_{1\dots n-1}), \dots, p_{ij}(x_{1\dots n-1}), \dots).$$

Now consider the general second order equation

$$(2) \quad F(x, u(x), \dots, u_{x_i}(x), \dots, u_{x_i x_j}(x), \dots) = 0.$$

Appropriate initial data will be functions

$$\overset{\circ}{u}, \quad \overset{\circ}{p}_i, \quad \overset{\circ}{p}_{ij}$$

satisfying

$$\begin{aligned} (a) \quad 0 &= F(x_{1\dots n-1}, 0, \overset{\circ}{u}(x_{1\dots n-1}), \dots, \overset{\circ}{p}_i(x_{1\dots n-1}), \dots, \overset{\circ}{p}_{ij}(x_{1\dots n-1}), \dots) \\ &= F(\Sigma(s)), \end{aligned}$$

*To avoid any confusion about the basic philosophy of the Cauchy problem, we emphasize that for a *quasi-linear second order* equation, the “initial conditions” $\overset{\circ}{u}, \overset{\circ}{p}_n$ are completely arbitrary, while for the *general first order* equation the “initial data” $\overset{\circ}{p}_n$ must satisfy (a) on page 29, and are essentially uniquely determined by the value at a single point—we have to include $\overset{\circ}{p}_n$ in the initial data just to show which of the possible solutions of (a) we are considering.

and

$$(b) \quad \begin{cases} \frac{\partial \overset{\circ}{u}}{\partial x_j} = p_{j0} & j < n \\ \frac{\partial \overset{\circ}{p}_i}{\partial x_j} = \overset{\circ}{p}_{ij} & i \leq n, j < n; \end{cases}$$

in other words, we really need only $\overset{\circ}{u}, \overset{\circ}{p}_n, \overset{\circ}{p}_{nn}$ satisfying (a), when the other $\overset{\circ}{p}_j$ and $\overset{\circ}{p}_{ij}$ are defined by (b). For the PDE (2) we define M to be **free for the initial data** $\overset{\circ}{u}, \overset{\circ}{p}_n, \overset{\circ}{p}_{nn}$ if

$$F_{p_{nn}}(\Sigma(s)) \neq 0 \quad \text{on } M.$$

In this case there is a unique function f defined in a neighborhood of any given point

$$\bullet = (x_{1\dots n-1}, 0, \overset{\circ}{u}(x_{1\dots n-1}), \dots, \overset{\circ}{p}_i(x_{1\dots n-1}), \dots, \overset{\circ}{p}_{ij}(x_{1\dots n-1}), \dots) \\ [(i, j) \neq (n, n)]$$

such that

$$\begin{cases} F(x, z, \dots p_i \dots p_{ij} \dots f(x, z, \dots p_i \dots p_{ij} \dots)) = 0 & \text{in this neighborhood} \\ f(\bullet) = \overset{\circ}{p}_{nn}(x_1, \dots, x_{n-1}). \end{cases}$$

So our PDE is equivalent to the equation

$$u_{x_n x_n} = f(x_1, \dots, x_n, u, \dots, u_{x_i}, \dots, u_{x_i x_j}, \dots) \quad [(i, j) \neq (n, n)]$$

expressing $u_{x_n x_n}$ in terms of u , the partials u_{x_i} , and the other second partial derivatives $u_{x_i x_j}$.

Now we are ready to decide when an arbitrary $(n-1)$ -dimensional submanifold $M \subset \mathbb{R}^n$ should be called free for a second order PDE. Again we begin with the quasi-linear equation

$$(I) \quad \sum_{i,j=1}^n A_{ij} u_{x_i x_j} = C.$$

It seems reasonable that the initial conditions for the Cauchy problem on M should be the value $\overset{\circ}{u}$ of u on M , together with the **normal derivative** u' of u on M ,

$$u'(p) = \lim_{h \rightarrow 0} \frac{u(p + h \cdot v(p)) - u(p)}{h},$$

where $\nu: M \rightarrow \mathbb{R}^n$ is the unit normal on M . This normal derivative is the same as

$$u'(p) = \nabla_{\nu(p)} u,$$

where ∇ denotes the ordinary covariant derivative in \mathbb{R}^n . From the value $\overset{\circ}{u}$ of u on M we can calculate any directional derivative $\nabla_{X_p} u$ for which X_p is tangent to M at p . So from $\overset{\circ}{u}$ and u' we can calculate *all* directional derivatives $\nabla_{Y_p} u$, for $p \in M$ and $Y_p \in \mathbb{R}^n_p$.

Now choose a diffeomorphism $\phi: \mathbb{R}^n \rightarrow \mathbb{R}^n$ such that $\phi(M) \subset \{x \in \mathbb{R}^n : x^n = 0\}$. We look for a solution of (I) of the form $u = \tilde{u} \circ \phi$. Substituting the expressions

$$(*) \quad \begin{cases} u_{x_i} = \sum_k \tilde{u}_{x_k} \cdot \phi^k_{x_i} \\ u_{x_i x_j} = \sum_{k,l} \tilde{u}_{x_k x_l} \phi^k_{x_i} \phi^l_{x_j} + \sum_k \tilde{u}_{x_k} \phi^k_{x_i x_j} \end{cases}$$

into (I), we obtain a quasi-linear equation for \tilde{u} ,

$$(I') \quad \sum_{i,j=1}^n \tilde{A}_{ij} \tilde{u}_{x_i x_j} = \tilde{C}.$$

Prescribing the value $\overset{\circ}{u}$ of u on M is equivalent to prescribing the value $\overset{\circ}{\tilde{u}}$ of \tilde{u} on $\{x \in \mathbb{R}^n : x^n = 0\}$. If we also know u' on M , then we know all directional derivatives of u on M , and consequently all directional derivatives of \tilde{u} on $\{x \in \mathbb{R}^n : x^n = 0\}$; in particular, we know $\partial \tilde{u} / \partial x_n$. So solving the Cauchy problem for (I) for the initial conditions $\overset{\circ}{u}, u'$ on M is equivalent to solving the Cauchy problem for (I') for given initial conditions $\overset{\circ}{\tilde{u}}, \overset{\circ}{p}_n$ on $\{x \in \mathbb{R}^n : x^n = 0\}$. Now we ask: what conditions on $(M, \overset{\circ}{u}, u')$ will make $\{x \in \mathbb{R}^n : x^n = 0\}$ free for the initial conditions $\overset{\circ}{\tilde{u}}, \overset{\circ}{p}_n$ for equation (I')? In other words, when will the coefficient \tilde{A}_{nn} of $\tilde{u}_{x_n x_n}$ in (I') be non-zero? From the derivation of equation (I') we see immediately that

$$\tilde{A}_{nn} = \sum_{i,j} A_{ij} \phi^n_{x_i} \phi^n_{x_j}.$$

Since $M = (\phi^n)^{-1}(0)$, the vector $(\phi^n_{x_1}, \dots, \phi^n_{x_n})$ is a multiple of the normal ν of M (compare pg. II.113). So for the PDE (I) we define the $(n-1)$ -dimensional submanifold $M \subset \mathbb{R}^n$ to be **free for the initial conditions** $\overset{\circ}{u}, u'$ if

$$\sum_{i,j} A_{ij} \nu_i \nu_j \neq 0 \quad \text{on } M$$

(in order to write this equation out for a point of M , we have to know the

values of u and the u_{x_i} at this point, since these occur as arguments of A_{ij} ; but we can compute these from the initial values $\overset{\circ}{u}, u'$. If M is free for the initial conditions $\overset{\circ}{u}, u'$, then equation (1) with the initial conditions $\overset{\circ}{u}, u'$ is equivalent to an equation for a function \tilde{u} expressing $\tilde{u}_{x_n x_n}$ in terms of \tilde{u} , first partials of \tilde{u} , and the remaining second partials of \tilde{u} , with initial conditions giving the values of \tilde{u} and \tilde{u}_{x_n} at points $(x_1, \dots, x_{n-1}, 0)$.

Now consider the general second order PDE

$$(2) \quad F(x, u(x), \dots, u_{x_i}(x), \dots, u_{x_i x_j}(x), \dots) = 0.$$

Appropriate initial data for the Cauchy problem on an $(n - 1)$ -dimensional submanifold $M \subset \mathbb{R}^n$ will be functions

$$\overset{\circ}{u}, \overset{\circ}{p}_i, \overset{\circ}{p}_{ij},$$

giving the values of u and its first and second partial derivatives on M . Of course, the $\overset{\circ}{p}_i$ can be determined by giving the normal derivative u' along M , which can be prescribed arbitrarily. But the $\overset{\circ}{p}_{ij}$ must satisfy

$$(a) \quad 0 = F(x, \overset{\circ}{u}(x), \dots, \overset{\circ}{p}_i(x), \dots, \overset{\circ}{p}_{ij}(x), \dots) = 0 \quad \text{for } x \in M,$$

as well as certain compatibility conditions; if M is the image of the map

$$(s_1, \dots, s_{n-1}) \mapsto (\sigma_1(s_1, \dots, s_{n-1}), \dots, \sigma_n(s_1, \dots, s_{n-1})) \in \mathbb{R}^n,$$

and we regard $\overset{\circ}{u}, \overset{\circ}{p}_i, \overset{\circ}{p}_{ij}$ as functions of (s_1, \dots, s_{n-1}) , then these conditions can be written as

$$(b) \quad \begin{cases} \frac{\partial \overset{\circ}{u}}{\partial s_j} = \sum_{i=1}^n \overset{\circ}{p}_i \cdot \frac{\partial \sigma_i}{\partial s_j} \\ \frac{\partial \overset{\circ}{p}_i}{\partial s_j} = \sum_{i=1}^n \overset{\circ}{p}_{ij} \cdot \frac{\partial \sigma_i}{\partial s_j}. \end{cases}$$

Once again, choose a diffeomorphism $\phi: \mathbb{R}^n \rightarrow \mathbb{R}^n$ such that $\phi(M) \subset \{x \in \mathbb{R}^n : x^n = 0\}$, and consider a solution of (2) of the form $u = \tilde{u} \circ \phi$. Equation (2) is equivalent to a second order PDE for \tilde{u}

$$(2') \quad \tilde{F}(x, \tilde{u}(x), \dots, \tilde{u}_{x_i}(x), \dots, \tilde{u}_{x_i x_j}(x), \dots) = 0,$$

and prescribing the functions $\overset{\circ}{u}, \overset{\circ}{p}_i, \overset{\circ}{p}_{ij}$ on M is equivalent to prescribing functions $\overset{\circ}{u}, \overset{\circ}{p}_i, \overset{\circ}{p}_{ij}$ on $\{x \in \mathbb{R}^n : x_n = 0\}$ which satisfy the conditions (a) and (b) for the equation (2') on this initial manifold. We want to know when $\{x \in \mathbb{R}^n : x_n = 0\}$ will be free for this initial data; thus we want to know when $\tilde{F}_{\tilde{p}_{nn}}$, evaluated at suitable points, is non-zero. Since we get equation (2') by substituting (*) into (2), we easily see that

$$\tilde{F}_{\tilde{p}_{nn}} = \sum_{i,j=1}^n F_{p_{ij}} \phi^n_{x_i} \phi^n_{x_j}.$$

So for the PDE (2) we define M to be **free for the initial data** $\overset{\circ}{u}, \overset{\circ}{p}_i, \overset{\circ}{p}_{ij}$ if

$$\sum_{i,j} F_{p_{ij}} v_i v_j \neq 0 \quad \text{on } M$$

(in order to write this equation out for a point of M we need to know the values of $u, u_{x_i}, u_{x_i x_j}$ on M , which are given to us). If M is free for the data $\overset{\circ}{u}, \overset{\circ}{p}_i, \overset{\circ}{p}_{ij}$, then the Cauchy problem for the general second order PDE (2) is equivalent to the Cauchy problem for an equation for a function \tilde{u} expressing $\tilde{u}_{x_n x_n}$ in terms of \tilde{u} , first partials of \tilde{u} , and the remaining second partials of \tilde{u} .

As in the case of first order equations we define M to be **characteristic** for the initial data $\overset{\circ}{u}, \overset{\circ}{p}_i, \overset{\circ}{p}_{ij}$ if M fails to be free in the worst possible way, that is, if

$$\sum_{i,j} F_{p_{ij}} v_i v_j = 0 \quad \text{on } M.$$

Since we will never consider PDE's of order higher than 2, we will not bother to carry out a similar discussion for these equations. We merely note that with the appropriate definitions, solving the Cauchy problem for a k^{th} order PDE when the initial manifold is free for the initial data is always equivalent to solving an equation

$$\frac{\partial^k u}{\partial x_n^k}(x) = f \left(x, u(x), \dots, \frac{\partial^l u}{\partial x_1^{i_1} \dots \partial x_n^{i_n}}, \dots \right),$$

in which the order i_n of any partial on the right with respect to x_n is $\leq k - 1$, with initial conditions for

$$u(x_1, \dots, x_{n-1}, 0), \dots, \frac{\partial^{k-1} u}{\partial x_n^{k-1}}(x_1, \dots, x_{n-1}, 0).$$

3. SYSTEMS OF FIRST ORDER PDE's

For an ordinary differential equation

$$(1) \quad u'(x) = f(x, u(x)),$$

we found that the existence of solutions was no harder to prove for the case of a function $u: \mathbb{R} \rightarrow \mathbb{R}^n$ than it was for the case of a function $u: \mathbb{R} \rightarrow \mathbb{R}$. So we could consider (1) to be a *system* of equations

$$u_i'(x) = f_i(x, u_1(x), \dots, u_n(x)).$$

This enabled us to solve an n^{th} order equation

$$(2) \quad u^{(n)}(x) = f(x, u(x), u'(x), \dots, u^{(n-1)}(x)),$$

for equation (2) is equivalent to the system of equations

$$(3) \quad \begin{cases} u' = u_1 \\ u_1' = u_2 \\ \vdots \\ u_{n-2}' = u_{n-1} \\ u_{n-1}'(x) = f(x, u(x), \dots, u_{n-1}(x)). \end{cases}$$

More precisely, if u satisfies (2), then $(u, u', \dots, u^{(n-1)})$ satisfies (3); conversely, if (u, u_1, \dots, u_{n-1}) satisfies (3), then u satisfies (2) [and moreover $u_i = u^{(i)}$]. Since (3) can be solved with any initial conditions $(u(x_0), \dots, u_{n-1}(x_0))$, equation (2) can be solved with any initial conditions $u(x_0), u'(x_0), \dots, u^{(n-1)}(x_0)$.

There is *no such general theorem* about systems of first order PDE's. If there were, the study of PDE's would certainly be much simpler, because, as we will now point out, the Cauchy problem for any PDE can be reduced to the Cauchy problem for a system of first order PDE's. Because of the considerations in the previous section, we will assume that the partials of u with respect to one of the variables, which we will call y , are explicitly expressed in terms of the partials with respect to the other variables, which we will call x_1, \dots, x_n . Thus we consider the equation

$$\frac{\partial^k u}{\partial y^k}(x_1, \dots, x_n, y) = f\left(x, y, u(x, y), \dots, \frac{\partial^l u}{\partial x_1^{i_1} \dots \partial x_n^{i_n} \partial y^j}, \dots\right);$$

the partial derivatives appearing on the right are all of order $l \leq k$, and the order j with respect to y is $\leq k - 1$.

In the now-standard trick* for this reduction, we might as well allow our equation to be a system itself; in other words, u can be a vector-valued function. If we let $u_i = \partial u / \partial x_i$ and $v = \partial u / \partial y$, then we have

$$\begin{aligned} \frac{\partial^{k-1} u}{\partial y^{k-1}} &= \frac{\partial^{k-2} \frac{\partial u}{\partial y}}{\partial y^{k-2}} = \frac{\partial^{k-2} v}{\partial y^{k-2}} \\ \frac{\partial^{k-1} u_i}{\partial y^{k-1}} &= \frac{\partial^{k-1} \frac{\partial u}{\partial x_i}}{\partial y^{k-1}} \\ &= \frac{\partial}{\partial x_i} \frac{\partial^{k-1} u}{\partial y^{k-1}} = \frac{\partial}{\partial x_i} \frac{\partial^{k-2} \frac{\partial u}{\partial y}}{\partial y^{k-2}} = \frac{\partial}{\partial x_i} \frac{\partial^{k-2} v}{\partial y^{k-2}} \\ \frac{\partial^{k-1} v}{\partial y^{k-1}} &= f(x, y, u(x, y), \dots), \end{aligned}$$

with obvious initial conditions for u, u_1, \dots, u_n, v . Notice that the order of all partial derivatives of u with respect to y on the right is now $\leq k - 2$, so that this is a system of order $\leq k - 1$; conversely, this Cauchy problem for this system of (vector-valued) functions u, u_1, \dots, u_n, v gives us a solution for our original Cauchy problem. Thus, by repeating this process enough times we finally obtain a system of first order PDE's.

As a simple specific example, where the notation will be less abstract, consider the Cauchy problem for the equation

$$u_{yy} = f(x, y, u, u_x, u_y, u_{xx}, u_{xy}).$$

We want to introduce u_1 for $\partial u / \partial x$ and v for $\partial u / \partial y$; for convenience, we will simply use α for $\partial u / \partial x$. Then our Cauchy problem is equivalent to a Cauchy problem for the first order system

$$\begin{aligned} (*) \quad u_y &= v \\ \alpha_y &= v_x \\ v_y &= f(x, y, u, \alpha, v, \alpha_x, v_x). \end{aligned}$$

for (u, α, v) .

* From mimeographed notes, J. F. Trèves, *Ovsjannikov theorem and hyperdifferential operators*, Notas Mat. **46** (1968); see L. Nirenberg, *An abstract form of the nonlinear Cauchy-Kowalewski theorem*, J. Differential Geometry, **6** (1972), 561-576.

Yet one further simplification is possible: we can reduce any first order system

$$u^i_y = F(x, y, \dots, u^j, \dots, u^j_x, \dots)$$

to a *quasi-linear* system. To do this, we simply introduce new functions p^j (representing $\partial u/\partial x_j$) and consider the system

$$\begin{aligned} u^i_y &= F^i(x, y, \dots, u^j, \dots, p^j, \dots) \\ p^i_y &= F^i_x + \sum_j F^i_{u_j} \cdot u^j_x + \sum_j F^i_{p^j} \cdot p^j_x. \end{aligned}$$

For the system (*), instead of using the p^j notation, let us use*

$$\begin{aligned} p &\text{ for } u_x \\ r &\text{ for } \alpha_x \\ s &\text{ for } v_x. \end{aligned}$$

Then the Cauchy problem for (*) is equivalent to a Cauchy problem for the system

$$\begin{aligned} (**) \quad & u_y = v \\ & \alpha_y = s \\ & v_y = f(x, y, u, \alpha, v, r, s) \\ & p_y = v_y \\ & r_y = s_x \\ & s_y = f_x + f_u \cdot p + f_\alpha \cdot r + f_v \cdot s + f_r \cdot r_x + f_s \cdot s_x. \end{aligned}$$

4. THE CAUCHY-KOWALEWSKI THEOREM

In this section we will consider the most general system of first order quasi-linear equations in the variables x_1, \dots, x_n, y , where the partials with respect to y are expressed in terms of the partials with respect to x_1, \dots, x_n . We thus have N equations for N unknown functions u_1, \dots, u_N :

$$\begin{aligned} \frac{\partial u_\alpha}{\partial y} &= \sum_{\beta=1}^N \sum_{i=1}^n A_{\alpha i}^\beta(x_1, \dots, x_n, y, u_1, \dots, u_N) \frac{\partial u_\beta}{\partial x_i} \\ &\quad + B_\alpha(x_1, \dots, x_n, y, u_1, \dots, u_N). \end{aligned}$$

* For second order equations in 2 variables, the symbols p, q, r, s, t are customarily used for $u_x, u_y, u_{xx}, u_{xy}, u_{yy}$.

[Notice that the symbol $A_{\alpha i}^{\beta}(x_1, \dots, x_n, y, u_1, \dots, u_N)$ is really an abbreviation for

$$A_{\alpha i}^{\beta}(x_1, \dots, x_n, y, u_1(x_1, \dots, x_n, y), \dots, u_N(x_1, \dots, x_n, y)),$$

and similarly for B_{α} .] We will prove that this system of equations has a solution u_1, \dots, u_N with given initial conditions

$$u_{\alpha}(x_1, \dots, x_n, 0) = \xi_{\alpha}(x_1, \dots, x_n).$$

The hitch is that we will have to assume that both the coefficients $A_{\alpha i}^{\beta}, B_{\alpha}$ and the initial conditions ξ_{α} are *real analytic*. Recall that a function $f: U \subset \mathbb{R}^m \rightarrow \mathbb{R}$ is real analytic if it can be expressed as a convergent sum

$$\sum_{\sigma_1, \dots, \sigma_m=0}^{\infty} c_{\sigma_1 \dots \sigma_m} (x_1 - a_1)^{\sigma_1} \cdots (x_m - a_m)^{\sigma_m}$$

in a neighborhood of each point (a_1, \dots, a_m) in its domain. We will also write this in the abbreviated form

$$\sum_{\sigma} c_{\sigma} (x - a)^{\sigma}.$$

4. **THEOREM (THE CAUCHY-KOWALEWSKI THEOREM).** Let ξ_{α} ($\alpha = 1, \dots, N$) be analytic functions in a neighborhood of (a_1, \dots, a_n) in \mathbb{R}^n , set $b_{\alpha} = \xi_{\alpha}(a_1, \dots, a_n)$, and let $A_{\alpha i}^{\beta}$ and B_{α} ($\alpha, \beta = 1, \dots, N; i = 1, \dots, n$) be analytic functions in a neighborhood of $(a_1, \dots, a_n, 0, b_1, \dots, b_N)$ in \mathbb{R}^{N+n+1} . Then there are unique analytic functions u_1, \dots, u_N in a neighborhood of (a_1, \dots, a_n) in \mathbb{R}^n satisfying

$$\begin{aligned} \frac{\partial u_{\alpha}}{\partial y} = & \sum_{\beta=1}^N \sum_{i=1}^n A_{\alpha i}^{\beta}(x_1, \dots, x_n, y, u_1, \dots, u_N) \frac{\partial u_{\beta}}{\partial x_i} \\ & + B_{\alpha}(x_1, \dots, x_n, y, u_1, \dots, u_N) \end{aligned}$$

with the initial conditions

$$u_{\alpha}(x_1, \dots, x_n, 0) = \xi_{\alpha}(x_1, \dots, x_n).$$

PROOF. We first make three slight simplifications.

(1) We can assume that all $a_i = 0$. For if we define

$$v_{\alpha}(x_1, \dots, x_n, y) = u_{\alpha}(x_1 + a_1, \dots, x_n + a_n, y),$$

then our equations and initial conditions are equivalent to equations of the same sort for v_α ,

$$\begin{aligned} \frac{\partial v_\alpha}{\partial y} = & \sum_{\beta=1}^N \sum_{i=1}^n A_{\alpha i}^\beta(x_1 + a_1, \dots, x_n + a_n, y, v_1, \dots, v_N) \frac{\partial v_\beta}{\partial x_i} \\ & + B_\alpha(x_1 + a_1, \dots, x_n + a_n, y, v_1, \dots, v_N), \end{aligned}$$

with the initial conditions

$$v_\alpha(x_1, \dots, x_n, 0) = \xi_\alpha(x_1 + a_1, \dots, x_n + a_n).$$

The functions $\bar{\xi}_\alpha(x_1, \dots, x_n) = \xi_\alpha(x_1 + a_1, \dots, x_n + a_n)$ are analytic in a neighborhood of 0 in \mathbb{R}^n , and the coefficients of the new equation are analytic in a neighborhood of $(0, \dots, 0, 0, \bar{\xi}_1(0, \dots, 0), \dots, \bar{\xi}_N(0, \dots, 0))$ in \mathbb{R}^{N+n+1} .

(2) We can further assume that the ξ_α are all 0. For if we now define

$$v_\alpha(x_1, \dots, x_n, y) = u_\alpha(x_1, \dots, x_n, y) - \xi_\alpha(x_1, \dots, x_n),$$

and for abbreviation set

$$C_k = v_k + \xi_k(x_1, \dots, x_n) \quad k = 1, \dots, N,$$

then our equations and initial conditions are equivalent to equations of the same sort for the v_α ,

$$\begin{aligned} \frac{\partial v_\alpha}{\partial y} = & \sum_{\beta=1}^N \sum_{i=1}^n A_{\alpha i}^\beta(x_1, \dots, x_n, y, C_1, \dots, C_N) \frac{\partial v_\beta}{\partial x_i} \\ & + \left[\sum_{\beta=1}^N \sum_{i=1}^n A_{\alpha i}^\beta(x_1, \dots, x_n, y, C_1, \dots, C_N) \cdot \frac{\partial \xi_\beta}{\partial x_i}(x_1, \dots, x_n) \right. \\ & \left. + B_\alpha(x_1, \dots, x_n, y, C_1, \dots, C_N) \right], \end{aligned}$$

with the initial conditions

$$v_\alpha(x_1, \dots, x_n, 0) = 0.$$

Notice that the coefficients of the new equation are analytic in a neighborhood of 0 in \mathbb{R}^{N+n+1} .

(3) We can assume finally that the $A_{\alpha i}^\beta$ and the B_α do not depend on y . For we can consider the equations in $N + 1$ unknowns η, u_1, \dots, u_N ,

$$\begin{aligned} \frac{\partial \eta}{\partial y} &= 1 \\ \frac{\partial u_\alpha}{\partial y} &= \sum_{\beta=1}^N \sum_{i=1}^n A_{\alpha i}^\beta(x_1, \dots, x_n, \eta, u_1, \dots, u_N) \frac{\partial u_\beta}{\partial x_i} \\ &\quad + B_\alpha(x_1, \dots, x_n, \eta, u_1, \dots, u_N), \end{aligned}$$

with initial conditions

$$\begin{aligned} \eta(x_1, \dots, x_n, 0) &= 0 \\ u_\alpha(x_1, \dots, x_n, 0) &= 0. \end{aligned}$$

To sum up, we can consider equations

$$\begin{aligned} (1) \quad \frac{\partial u_\alpha}{\partial y} &= \sum_{\beta=1}^N \sum_{i=1}^n A_{\alpha i}^\beta(x_1, \dots, x_n, u_1, \dots, u_N) \frac{\partial u_\beta}{\partial x_i} \\ &\quad + B_\alpha(x_1, \dots, x_n, u_1, \dots, u_N) \end{aligned}$$

with initial conditions

$$(2) \quad u_\alpha(x_1, \dots, x_n, 0) = 0;$$

the functions $A_{\alpha i}^\beta$ and B_α are analytic in a neighborhood of 0 in \mathbb{R}^{N+n} , and we are looking for a solution u in a neighborhood of 0. We expand the analytic functions $A_{\alpha i}^\beta$ and B_α around 0 as

$$\begin{aligned} (3) \quad A_{\alpha i}^\beta(x_1, \dots, x_n, z_1, \dots, z_N) &= \sum a_{\alpha i; \sigma_1, \dots, \sigma_n, \tau_1, \dots, \tau_N}^\beta x_1^{\sigma_1} \dots x_n^{\sigma_n} z_1^{\tau_1} \dots z_N^{\tau_N} \\ &= \sum_{\sigma, \tau} a_{\alpha i; \sigma, \tau}^\beta x^\sigma z^\tau \end{aligned}$$

$$\begin{aligned} (4) \quad B_\alpha(x_1, \dots, x_n, z_1, \dots, z_N) &= \sum b_{\alpha; \sigma_1, \dots, \sigma_n, \tau_1, \dots, \tau_N} x_1^{\sigma_1} \dots x_n^{\sigma_n} z_1^{\tau_1} \dots z_N^{\tau_N} \\ &= \sum_{\sigma, \tau} b_{\alpha; \sigma, \tau} x^\sigma z^\tau. \end{aligned}$$

We claim, first of all, that there is at most one analytic solution

$$\begin{aligned} (5) \quad u_\alpha(x_1, \dots, x_n, y) &= \sum c_{\alpha; \sigma_1, \dots, \sigma_n, \rho} x_1^{\sigma_1} \dots x_n^{\sigma_n} y^\rho \\ &= \sum_{\sigma, \rho} c_{\alpha; \sigma, \rho} x^\sigma y^\rho \end{aligned}$$

of (1) and (2). We just have to show that the coefficients $c_{\alpha;\sigma,\rho}$ are completely determined by those of $A_{\alpha i}^\beta$ and B_α . From the particular way they are determined, we will then be able to show that the resulting series (5) converges, thereby also proving existence.

For a given n -tuple $\sigma = (\sigma_1, \dots, \sigma_n)$, let $\sigma + \delta_i$ be the n -tuple

$$\sigma + \delta_i = (\sigma_1, \dots, \sigma_i + 1, \dots, \sigma_n).$$

Then if the u_α are given by (5), we can write

$$(6) \quad \begin{cases} \frac{\partial u_\beta}{\partial x_i}(x_1, \dots, x_n, y) = \sum_{\sigma, \rho} (\sigma_i + 1) c_{\beta; \sigma + \delta_i, \rho} x^\sigma y^\rho \\ \frac{\partial u_\alpha}{\partial y}(x_1, \dots, x_n, y) = \sum_{\sigma, \rho} (\rho + 1) c_{\alpha; \sigma, \rho+1} x^\sigma y^\rho. \end{cases}$$

So if the u_α in (5) satisfy (1), then

$$(7) \quad \begin{cases} \sum_{\sigma, \rho} (\rho + 1) c_{\alpha; \sigma, \rho+1} x^\sigma y^\rho \\ = \sum_{\beta=1}^N \sum_{i=1}^n \left\{ \sum_{\sigma, \tau} a_{\alpha i; \sigma, \tau}^\beta x^\sigma \left(\sum_{\sigma, \rho} c_{1; \sigma, \rho} x^\sigma y^\rho \right)^{\tau_1} \cdots \left(\sum_{\sigma, \rho} c_{N; \sigma, \rho} x^\sigma y^\rho \right)^{\tau_N} \right\} \\ \quad \cdot \sum_{\sigma, \rho} (\sigma_i + 1) c_{\beta; \sigma + \delta_i, \rho} x^\sigma y^\rho \\ + \sum_{\sigma, \tau} b_{\alpha; \sigma, \tau} x^\sigma \left(\sum_{\sigma, \rho} c_{1; \sigma, \rho} x^\sigma y^\rho \right)^{\tau_1} \cdots \left(\sum_{\sigma, \rho} c_{N; \sigma, \rho} x^\sigma y^\rho \right)^{\tau_N}. \end{cases}$$

Now there is no need to become unduly frightened by this expression. After we expand everything out, we will have an expression of the form

$$(8) \quad \begin{aligned} \sum_{\sigma, \rho} (\rho + 1) c_{\alpha; \sigma, \rho+1} x^\sigma y^\rho &= \sum_{\alpha, \sigma, \rho} P_{\alpha, \sigma, \rho} (a_{\xi j; \mu, v}^\eta, b_{\xi; \mu, v}, c_{\xi; \mu, v}) \\ &= \sum_{\alpha, \sigma, \rho} P_{\alpha, \sigma, \rho} (a, b, c) \quad \text{for short,} \end{aligned}$$

where each $P_{\alpha, \sigma, \rho}$ is a polynomial in certain of the $a_{\xi j; \mu, v}^\eta$, $b_{\xi; \mu, v}$, and $c_{\xi; \mu, v}$. Just which of these appear as arguments of $P_{\alpha, \sigma, \rho}$ depends on (σ, ρ) ; the only important thing for us to note is that

$$(A) \quad P_{\alpha, \sigma, \rho} \text{ depends only on those } c_{\xi; \mu, v} \text{ with } v \leq \rho.$$

Notice that all the information in equation (1) enters into (8) as the *arguments* of the polynomials $P_{\alpha,\sigma,\rho}$. These polynomials themselves *do not depend* on the $A_{\alpha i}^\beta$ or B_α , or on the $c_{\xi;\mu,\nu}$:

(B) The polynomials $P_{\alpha,\sigma,\rho}$ are “universal polynomials” depending only on N and n .

Finally, we note that

(C) The coefficients of $P_{\alpha,\sigma,\rho}$ are *non-negative* integers.

Now if (8) is to hold for all sufficiently small (x_1, \dots, x_n, y) , then we must have

$$(9) \quad (\rho + 1)c_{\alpha;\sigma,\rho+1} = P_{\alpha,\sigma,\rho}(a, b, c).$$

Together with the initial condition (2), which gives us $c_{\alpha;\sigma,0} = 0$, we can now calculate all $c_{\alpha;\sigma,\rho}$ recursively from (9), since (A) shows us that the right side involves only $c_{\xi;\mu,\nu}$ with $\nu \leq \rho$. This proves uniqueness.

To prove existence, we must show that the series (5) converges, when the $c_{\alpha;\sigma,\rho}$ are computed from (9). We will show absolute convergence for sufficiently small (x_1, \dots, x_n, y) . This is done by the following trick, called the **method of majorants**. Consider another set of equations

$$(1') \quad \begin{aligned} \frac{\partial u_\alpha}{\partial y} = & \sum_{\beta=1}^N \sum_{i=1}^n \bar{A}_{\alpha i}^\beta(x_1, \dots, x_n, u_1, \dots, u_N) \frac{\partial u_\beta}{\partial x_i} \\ & + \bar{B}_\alpha(x_1, \dots, x_n, u_1, \dots, u_N) \end{aligned}$$

which “majorizes” (1), that is, which satisfies

$$(10) \quad \begin{cases} |a_{\xi j;\mu,\nu}^\eta| \leq \bar{a}_{\xi j;\mu,\nu}^\eta \\ |b_{\xi;\mu,\nu}| \leq \bar{b}_{\xi;\mu,\nu} \end{cases} \quad \text{for all } \xi, \eta, j, \mu, \nu.$$

Suppose that equation (1'), with the same initial condition (2), has an analytic solution

$$(5') \quad u_\alpha(x_1, \dots, x_n, y) = \sum_{\sigma, \rho} \bar{c}_{\alpha; \sigma, \rho} x^\sigma y^\rho.$$

Then we must have

$$(8') \quad (\rho + 1) \bar{c}_{\alpha; \sigma, \rho+1} = P_{\alpha, \sigma, \rho}(\bar{a}, \bar{b}, \bar{c}),$$

where, by (B), the $P_{\alpha, \sigma, \rho}$ are the *same* universal polynomials as in (8). We claim that we can then conclude that

$$(11) \quad |c_{\alpha; \sigma, \rho}| \leq \bar{c}_{\alpha; \sigma, \rho}.$$

The proof is by induction. It is clear for $\rho = 0$. Now assume it is true for ρ . Then

$$\begin{aligned} |c_{\alpha; \sigma, \rho+1}| &= \frac{1}{\rho + 1} |P_{\alpha, \sigma, \rho}(a, b, c)| && \text{by (8)} \\ &\leq \frac{1}{\rho + 1} P_{\alpha, \sigma, \rho}(|a|, |b|, |c|) && \text{by (C)} \\ &\leq \frac{1}{\rho + 1} P_{\alpha, \sigma, \rho}(\bar{a}, \bar{b}, \bar{c}) && \text{by (C) and (10)} \\ &= \bar{c}_{\alpha; \sigma, \rho+1} && \text{by (8')}. \end{aligned}$$

This completes the induction proof. But now the convergence of (5'), together with (11), proves the absolute convergence of (5). So the proof of the theorem will be complete once we show that some majorant of equation (1) has an analytic solution. This will be comparatively easy.

For some $r > 0$, the power series (3) converges for the point (x, z) with all $x_j = z_\xi = r$. Then the terms

$$a_{\alpha i; \sigma, \tau}^\beta r^{\sigma_1 + \dots + \tau_N}$$

in this infinite sum must approach 0, and consequently are surely bounded: there is some M with

$$|a_{\alpha i; \sigma, \tau}^\beta| \leq \frac{M}{r^{\sigma_1 + \dots + \tau_N}}$$

for all σ, τ . For r small enough and M large enough, this equation holds for each $\alpha, \beta \leq N$ and $i \leq n$. Similarly, we can assume that we have the same

estimate for each $|b_{\alpha;\sigma,\tau}|$. We thus also have the weaker estimates

$$|a_{\alpha i;\sigma,\tau}^\beta|, |b_{\alpha;\sigma,\tau}| \leq \frac{M}{r^{\sigma_1+\dots+\tau_N}} \cdot \frac{(\sigma_1 + \dots + \tau_N)!}{\sigma_1! \dots \tau_N!}.$$

So if we take $\bar{a}_{\alpha i;\sigma,\tau}^\beta$ and $\bar{b}_{\alpha;\sigma,\tau}$ to be the expression on the right side of this inequality, then equation (1') majorizes equation (1), and we just have to show that the solution of (1') with the initial condition (2) is analytic. Since

$$\begin{aligned} \sum_{\sigma,\tau} \bar{a}_{\alpha i;\sigma,\tau}^\beta x^\sigma z^\tau &= \sum_{\sigma,\tau} \bar{b}_{\alpha;\sigma,\tau} x^\sigma z^\tau \\ &= M \sum_{\sigma,\tau} \left(\frac{x}{r}\right)^\sigma \left(\frac{z}{r}\right)^\tau \frac{(\sigma_1 + \dots + \tau_N)!}{\sigma_1! \dots \tau_N!} \\ &= \frac{M}{1 - \frac{(x_1 + \dots + z_N)}{r}}, \end{aligned}$$

we are dealing with the equations

$$\begin{cases} \frac{\partial u_\alpha}{\partial y} = \frac{M}{1 - \frac{(x_1 + \dots + u_N)}{r}} \left(\sum_{\beta=1}^N \sum_{i=1}^n \frac{\partial u_\beta}{\partial x_i} + 1 \right) \\ u_\alpha(x_1, \dots, x_n, 0) = 0. \end{cases}$$

Since the equations for the different u_α are all the same, and since the x_i enter only in the combination $X = x_1 + \dots + x_n$, it seems reasonable to look for a solution with all

$$u_\alpha(x_1, \dots, x_n, y) = U(x_1 + \dots + x_n, y) = U(X, y).$$

This gives us the single equation

$$\begin{cases} \frac{\partial U}{\partial y} = \frac{M}{1 - \frac{X + NU}{r}} \left(Nn \frac{\partial U}{\partial x} + 1 \right) \\ U(X, 0) = 0. \end{cases}$$

This is a first order equation, and hence one which, in theory, we can deal with.

The simplest thing, at the moment, is just to check that

$$U(X, y) = \frac{r - X}{(n + 1)N} - \frac{\sqrt{(r - X)^2 - 2N(n + 1)Mr y}}{N(n + 1)}$$

is the desired solution, and that it is analytic in a neighborhood of 0. ♦

Although the Cauchy-Kowalewski Theorem is the most general result in the theory of PDE's, its usefulness is greatly restricted by the fact that both the *coefficients* and the *initial conditions* must be real analytic. We would naturally like to know whether these hypotheses are somehow dictated by the very nature of the problem, or whether they represent merely a defect in our method of proof. [One source of difficulty may be the fact that in one respect the theorem proves too much, since it is formulated for an *arbitrary* system of first order quasi-linear equations. Although it would be nice to solve any such system, this problem does not bear directly on the problem of solving a single higher order PDE, because only very special sorts of systems of first order equations are derived from higher order equations; given an arbitrary system of first order equations with initial conditions, we generally cannot find a single higher order equation with initial conditions that is equivalent to it.]

The necessity of having *analytic coefficients* in the Cauchy-Kowalewski Theorem is demonstrated by the famous example of Hans Lewy [1],

$$\begin{cases} \frac{\partial u_1}{\partial x_1} = \frac{\partial u_2}{\partial x_2} - 2x_2 \frac{\partial u_1}{\partial x_3} - 2x_1 \frac{\partial u_2}{\partial x_3} - f'(x_3) \\ \frac{\partial u_2}{\partial x_1} = -\frac{\partial u_1}{\partial x_2} + 2x_1 \frac{\partial u_1}{\partial x_3} - 2x_2 \frac{\partial u_2}{\partial x_3}. \end{cases}$$

If f is C^∞ but not analytic, then this system has no solutions at all (let alone solutions with arbitrary initial conditions). By the way, this system can be considered as the following single equation for the complex-valued function $u = u_1 + iu_2$:

$$-\frac{\partial u}{\partial x_1} - i \frac{\partial u}{\partial x_2} + 2i(x_1 + ix_2) \frac{\partial u}{\partial x_3} = f'(x_3).$$

There are also cases where *analytic initial conditions* are necessary, for we will soon see that there are simple PDE's, with analytic coefficients, that cannot have solutions with given initial conditions unless these conditions are analytic. So in a certain respect the Cauchy-Kowalewski theorem gives the best possible result in these cases. On the other hand, it turns out that the Cauchy problem isn't even the one which we want to pose for these equations. Moreover, there is a wide class of equations where the Cauchy problem is a natural one, but where analyticity is much too severe a restriction.

5. CLASSIFICATION OF SECOND ORDER PDE's

In our first forage into the uncharted lands of higher order PDE's, it is natural that we first restrict our attention to those of second order:

$$F\left(x_1, \dots, x_n, u(x_1, \dots, x_n), \frac{\partial u}{\partial x_1}(x_1, \dots, x_n), \dots, \frac{\partial^2 u}{\partial x_n^2}(x_1, \dots, x_n)\right) = 0.$$

As a matter of fact, we will never get anywhere beyond this. Moreover, we will deal almost exclusively with equations in only two variables,

$$F\left(x, y, u(x, y), \frac{\partial u}{\partial x}(x, y), \frac{\partial u}{\partial y}(x, y), \frac{\partial^2 u}{\partial x^2}(x, y), \frac{\partial^2 u}{\partial x \partial y}(x, y), \frac{\partial^2 u}{\partial y^2}(x, y)\right) = 0,$$

or in abbreviated form

$$F(x, y, u, p, q, r, s, t) = 0.$$

Even nowadays there are certain phenomena about second order PDE's which are much more completely understood in the two variable case than in higher dimensions, but the particular results that we are after can all be handled in a uniform way that works in all dimensions. However, a whole book would be required in order to reach them. So we will instead use quite classical methods to analyze second order PDE's in just 2 variables. Fortunately, the 2 variable case happens to be just the one we are interested in.

We begin by singling out the *semi-linear* equations

$$\begin{aligned} \text{(I)} \quad 0 &= a(x, y)u_{xx} + 2b(x, y)u_{xy} + c(x, y)u_{yy} + f(x, y, u, u_x, u_y) \\ &= L(u) + f. \end{aligned}$$

For such an equation, $L(u)$ is called the “principal part”, and we will often denote the remaining part, involving only lower order derivatives, by “...”. There is a classification for these equations which is closely related to the classification of algebraic equations of the form

$$z = ax^2 + 2bxy + cy^2 = \left\langle (x, y), (x, y) \cdot \begin{pmatrix} a & b \\ b & c \end{pmatrix} \right\rangle,$$

with a, b, c not all 0. We briefly remind the reader how this classification goes (it is essentially the same as the classification of points on a surface in Chapter 2). We choose two orthonormal eigenvectors $X_1, X_2 \in \mathbb{R}^2$ for the symmetric matrix $\begin{pmatrix} a & b \\ b & c \end{pmatrix}$, with corresponding eigenvalues λ_1, λ_2 . Then

$$\begin{aligned} \left\langle \phi X_1 + \psi X_2, (\phi X_1 + \psi X_2) \cdot \begin{pmatrix} a & b \\ b & c \end{pmatrix} \right\rangle &= \langle \phi X_1 + \psi X_2, \phi \lambda_1 X_1 + \psi \lambda_2 X_2 \rangle \\ &= \lambda_1 \phi^2 + \lambda_2 \psi^2. \end{aligned}$$

So if we use ϕ and ψ as new coordinates for \mathbb{R}^2 , our equation becomes

$$z = \lambda_1 \phi^2 + \lambda_2 \psi^2.$$

We can express this statement a little more precisely in terms of the linear transformation $S = (\phi, \psi): \mathbb{R}^2 \rightarrow \mathbb{R}^2$ defined by

$$S(X_1) = (1, 0), \quad S(X_2) = (0, 1).$$

Since

$$S(x, y) = (\phi(x, y), \psi(x, y)) = \phi(x, y)S(X_1) + \psi(x, y)S(X_2),$$

the functions ϕ and ψ are just the coordinates of (x, y) with respect to X_1 and X_2 :

$$(x, y) = \phi(x, y)X_1 + \psi(x, y)X_2.$$

So we obtain

$$\begin{aligned} \text{(II)} \quad & ax^2 + 2bxy + cy^2 \\ &= \left\langle (x, y), (x, y) \cdot \begin{pmatrix} a & b \\ b & c \end{pmatrix} \right\rangle \\ &= \left\langle \phi(x, y)X_1 + \psi(x, y)X_2, (\phi(x, y)X_1 + \psi(x, y)X_2) \cdot \begin{pmatrix} a & b \\ b & c \end{pmatrix} \right\rangle \\ &= \langle \phi(x, y)X_1 + \psi(x, y)X_2, \phi(x, y)\lambda_1 X_1 + \psi(x, y)\lambda_2 X_2 \rangle \\ &= \lambda_1 [\phi(x, y)]^2 + \lambda_2 [\psi(x, y)]^2. \end{aligned}$$

These algebraic manipulations are often expressed slightly differently. We can write equation (II) as

$$\begin{aligned} (x, y) \begin{pmatrix} a & b \\ b & c \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} &= (\phi(x, y), \psi(x, y)) \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix} \begin{pmatrix} \phi(x, y) \\ \psi(x, y) \end{pmatrix} \\ &= S(x, y) \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix} [S(x, y)]^t, \end{aligned}$$

where t denotes the transpose. If Q is the matrix of the linear transformation S , then we can write

$$\begin{aligned} (x, y) \begin{pmatrix} a & b \\ b & c \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} &= [(x, y) \cdot Q] \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix} [(x, y) \cdot Q]^t \\ &= (x, y) \left[Q \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix} Q^t \right] \begin{pmatrix} x \\ y \end{pmatrix} \quad \text{for all } (x, y), \end{aligned}$$

which implies that

$$(III) \quad \begin{pmatrix} a & b \\ b & c \end{pmatrix} = Q \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix} Q^t.$$

It is not hard to see exactly what the matrix Q is. Since S^{-1} takes $(1, 0)$ to X_1 and $(0, 1)$ to X_2 , its matrix has X_1 and X_2 as its two columns,

$$Q^{-1} = (X_1^t, X_2^t).$$

Moreover, since X_1 and X_2 are orthonormal, we have $Q^{-1}(Q^{-1})^t = I$. So

$$Q = (Q^{-1})^t = \begin{pmatrix} X_1 \\ X_2 \end{pmatrix}.$$

Since $Q^{-1} = Q^t$, we can also write (III) as

$$(IV) \quad \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix} = Q^t \begin{pmatrix} a & b \\ b & c \end{pmatrix} Q.$$

The reduction (II) [or its equivalent (IV)] shows that the equations $z = ax^2 + 2bxy + cy^2$ fall into three classes:

Elliptic Case: $ac - b^2 > 0$; equivalently, λ_1 and λ_2 have the same sign

Hyperbolic Case: $ac - b^2 < 0$; equivalently, λ_1 and λ_2 have opposite signs

Parabolic Case: $ac - b^2 = 0$; $\lambda_1 = 0$ or $\lambda_2 = 0$.

We introduce a similar classification for semi-linear PDE's

$$(I) \quad a(x, y)u_{xx} + 2b(x, y)u_{xy} + c(x, y)u_{yy} + \cdots = 0.$$

If a_0, b_0, c_0 are the values of the functions a, b, c at (x_0, y_0) , then we say that equation (I) is

elliptic at (x_0, y_0) if $a_0c_0 - b_0^2 > 0$

hyperbolic at (x_0, y_0) if $a_0c_0 - b_0^2 < 0$

parabolic at (x_0, y_0) if $a_0c_0 - b_0^2 = 0$

(but not all of a_0, b_0, c_0 are 0).

Naturally we say that equation (I) is **elliptic** in an open set U if it is elliptic at each point $(x, y) \in U$, etc. The simplest examples of equations of these three types are the “normal forms”

$$(E) \quad u_{xx} + u_{yy} + \cdots = 0$$

$$(H) \quad u_{xx} - u_{yy} + \cdots = 0$$

$$(P) \quad u_{xx} + \cdots = 0.$$

As always, “ \dots ” denotes terms which do not involve any second derivatives. There is in addition an alternative normal form in the hyperbolic case,

$$(H') \quad u_{xy} + \cdots = 0$$

(corresponding to the possibility of writing the equation for a hyperbola in the form $xy = 1$).

We would like to see if equation (I) can be reduced to a normal form by writing it in terms of a function v defined by

$$(V) \quad u(x, y) = v(\phi(x, y), \psi(x, y));$$

here (ϕ, ψ) is supposed to be a differentiable map from \mathbb{R}^2 to \mathbb{R}^2 with differentiable inverse. Denoting a typical point in the domain of v by (ξ, η) , and the partials of v by v_ξ and v_η , we compute that

$$u_x = v_\xi \phi_x + v_\eta \psi_x, \quad u_y = v_\xi \phi_y + v_\eta \psi_y$$

and then that

$$(VI) \quad \begin{cases} u_{xx} = v_{\xi\xi} \phi_x^2 + 2v_{\xi\eta} \phi_x \psi_x + v_{\eta\eta} \psi_x^2 + \cdots \\ u_{xy} = v_{\xi\xi} \phi_x \phi_y + v_{\xi\eta} (\phi_x \psi_y + \phi_y \psi_x) + v_{\eta\eta} \psi_x \psi_y + \cdots \\ u_{yy} = v_{\xi\xi} \phi_y^2 + 2v_{\xi\eta} \phi_y \psi_y + v_{\eta\eta} \psi_y^2 + \cdots \end{cases}$$

where “ \dots ” again denotes terms which do not involve any second derivatives. [Naturally, if the derivatives of u are evaluated at (x, y) , then the derivatives of ϕ and ψ are evaluated at (x, y) , while those for v are evaluated at $(\phi(x, y), \psi(x, y))$.] From this we easily see that

$$(VII) \quad \begin{cases} au_{xx} + 2bu_{xy} + cu_{yy} = \alpha v_{\xi\xi} + 2\beta v_{\xi\eta} + \gamma v_{\eta\eta} + \cdots \\ \text{where} \\ \alpha = a\phi_x^2 + 2b\phi_x\phi_y + c\phi_y^2 \\ \beta = a\phi_x\psi_x + b(\phi_x\psi_y + \phi_y\psi_x) + c\phi_y\psi_y \\ \gamma = a\psi_x^2 + 2b\psi_x\psi_y + c\psi_y^2 \\ \text{or equivalently} \\ \begin{pmatrix} \alpha & \beta \\ \beta & \gamma \end{pmatrix} = \begin{pmatrix} \phi_x & \phi_y \\ \psi_x & \psi_y \end{pmatrix} \begin{pmatrix} a & b \\ b & c \end{pmatrix} \begin{pmatrix} \phi_x & \psi_x \\ \phi_y & \psi_y \end{pmatrix}. \end{cases}$$

Notice that the last part of (VII) shows that

$$(VIII) \quad \alpha\gamma - \beta^2 = (ac - b^2)(\phi_x\psi_y - \phi_y\psi_x)^2;$$

therefore the type of the equation for v is always the same as the type for u .

In one case, purely algebraic manipulations will reduce our equation to normal form:

5. PROPOSITION. Suppose that the equation

$$(I) \quad au_{xx} + bu_{xy} + cu_{yy} + \cdots = 0$$

has *constant* coefficients a, b, c in the principal part. Then there is a non-singular linear transformation $(\phi, \psi): \mathbb{R}^2 \rightarrow \mathbb{R}^2$ having the property that if v is defined by

$$(V) \quad u(x, y) = v(\phi(x, y), \psi(x, y)),$$

then u satisfies (I) if and only if v satisfies a certain equation of the form (E), (H), or (P). In the hyperbolic case, we can also find (ϕ, ψ) so that u satisfies (I) if and only if v satisfies a certain equation of the form (H').

PROOF. Equation (IV) shows that we can choose a constant matrix $Q = \begin{pmatrix} \phi_x & \psi_x \\ \phi_y & \psi_y \end{pmatrix}$ so that

$$\begin{pmatrix} \alpha & \beta \\ \beta & \gamma \end{pmatrix} = \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix} \quad \text{in equation (VII).}$$

Since $\det Q \neq 0$, the linear transformation (ϕ, ψ) is non-singular. If we define v by (V), then (VII) shows that equation (I) for u is equivalent to the equation

$$(I) \quad \lambda_1 v_{\xi\xi} + \lambda_2 v_{\eta\eta} + \cdots = 0$$

for v . If we make a further change of coordinates by defining

$$\tilde{v}(\rho, \sigma) = v(r\rho, s\sigma) \quad r, s \text{ constants,}$$

then

$$\tilde{v}_{\rho\rho} = r^2 v_{\xi\xi} \quad \text{and} \quad \tilde{v}_{\sigma\sigma} = s^2 v_{\eta\eta}.$$

So we can also arrange for λ_1 and λ_2 to be ± 1 in (I). Then we have equations equivalent to (E), (H), or (P) [we may have to interchange the names of ξ and η].

The form (H') is obtained by analogy with the fact that the equation $x^2 - y^2 = 1$ becomes $4\bar{x}\bar{y} = 1$ when we perform the substitution $\bar{x} = \frac{1}{2}(x + y)$, $\bar{y} = \frac{1}{2}(x - y)$. We define

$$(2) \quad w(\rho, \sigma) = v\left(\frac{\rho + \sigma}{2}, \frac{\rho - \sigma}{2}\right).$$

Then

$$w_\rho = \frac{1}{2}v_\xi + \frac{1}{2}v_\eta$$

$$w_{\rho\sigma} = \frac{1}{2}\left(\frac{1}{2}v_{\xi\xi} - \frac{1}{2}v_{\xi\eta}\right) + \frac{1}{2}\left(\frac{1}{2}v_{\eta\xi} - \frac{1}{2}v_{\eta\eta}\right) = \frac{1}{4}(v_{\xi\xi} - v_{\eta\eta}).$$

So an equation of the form (H) for v is equivalent to one of the form (H') for w . ♦

The same method that was used in this proof will clearly enable us to reduce the general semi-linear equation (I) to an equation which has the normal form *at one point* (x_0, y_0) . But to obtain the normal form in a whole neighborhood, we have to work much harder. We consider the elliptic case first.

6. THEOREM. Suppose that the equation

$$(I) \quad a(x, y)u_{xx} + 2b(x, y)u_{xy} + c(x, y)u_{yy} + \cdots = 0$$

is elliptic in a neighborhood of (x_0, y_0) . Then there is a differentiable map (ϕ, ψ) from a neighborhood of (x_0, y_0) into \mathbb{R}^2 , with differentiable inverse, having the property that if v is defined by

$$(V) \quad u(x, y) = v(\phi(x, y), \psi(x, y)),$$

then u satisfies (I) if and only if v satisfies a certain equation in the normal form (E).

PROOF. It obviously suffices to find (ϕ, ψ) so that in equation (VII) we have $\alpha = \gamma$ and $\beta = 0$. So it suffices to find (ϕ, ψ) with

$$(I) \quad a\phi_x^2 + 2b\phi_x\phi_y + c\phi_y^2 = a\psi_x^2 + 2b\psi_x\psi_y + c\psi_y^2$$

$$(2) \quad a\phi_x\psi_x + b(\phi_x\psi_y + \phi_y\psi_x) + c\phi_y\psi_y = 0,$$

and $\phi_x\psi_y - \phi_y\psi_x \neq 0$ at (x_0, y_0) . This is precisely the problem of introducing isothermal coordinates for the metric $a dx \otimes dx + b[dx \otimes dy + dy \otimes dx] + c dy \otimes dy$, which we solved in Addendum I to Chapter 9. ♦

In our proof of the existence of isothermal coordinates, we showed that (1) and (2) are equivalent to the “Beltrami equations”

$$(a) \quad \phi_x = \frac{b\psi_x + c\psi_y}{\sqrt{ac - b^2}}, \quad \phi_y = -\frac{a\psi_x + b\psi_y}{\sqrt{ac - b^2}}.$$

Note that if (a) is to hold, then we must have

$$(b) \quad \frac{\partial}{\partial x} \left(\frac{a\psi_x + b\psi_y}{W} \right) + \frac{\partial}{\partial y} \left(\frac{b\psi_x + c\psi_y}{W} \right) = 0, \quad W = \sqrt{ac - b^2}.$$

Conversely, if (b) holds for some ϕ , then there is ψ satisfying (a); moreover, the Jacobian of (ϕ, ψ) is

$$\phi_x \psi_y - \phi_y \psi_x = -\frac{1}{W}(a\phi_x^2 + 2b\phi_x \phi_y + c\phi_y^2),$$

which is non-zero if $(\phi_x, \phi_y) \neq (0, 0)$. So solving (a) is equivalent to solving (b), which is itself elliptic [with the very same principal part as (I)]. Had we not already solved equation (a), we would be in the embarrassing position of needing to know that elliptic equations have solutions before we could reduce them to normal form.

In the hyperbolic case, the same line of reasoning leads us into precisely this difficulty, and thus requires results from section 7. However, there is also an elementary argument.

7. THEOREM. Suppose that the equation

$$(I) \quad a(x, y)u_{xx} + 2b(x, y)u_{xy} + c(x, y)u_{yy} + \cdots = 0$$

is hyperbolic at (x_0, y_0) . Then there is a differentiable map (ϕ, ψ) from a neighborhood of (x_0, y_0) into \mathbb{R}^2 , with differentiable inverse, having the property that if v is defined by

$$(V) \quad u(x, y) = v(\phi(x, y), \psi(x, y)),$$

then u satisfies (I) if and only if v satisfies a certain equation in the normal form (H). The same result holds for a certain equation in the normal form (H').

FIRST PROOF. We claim, first, that we can assume that $c_0 = c(x_0, y_0) \neq 0$. For suppose that $c_0 = 0$. Choose (ϕ, ψ) to be a linear transformation with matrix $\begin{pmatrix} 1 & 0 \\ \lambda & 1 \end{pmatrix}$. Then at (x_0, y_0) the coefficients α, β, γ of the equation for v

are, by (VII),

$$\begin{pmatrix} \alpha & \beta \\ \beta & \gamma \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ \lambda & 1 \end{pmatrix} \begin{pmatrix} a_0 & b_0 \\ b_0 & 0 \end{pmatrix} \begin{pmatrix} 1 & \lambda \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} a_0 & \lambda a_0 + b_0 \\ \lambda a_0 + b_0 & \lambda^2 a_0 + 2\lambda b_0 \end{pmatrix}.$$

Since we must have $a_0 \neq 0$ or $b_0 \neq 0$, we can certainly choose λ with $\lambda^2 a_0 + 2\lambda b_0 \neq 0$.

So we assume that $c(x_0, y_0) \neq 0$. To achieve the normal form (H), it now clearly suffices to choose (ϕ, ψ) so that in equation (VII) we have $\alpha = -\gamma$ and $\beta = 0$. Solving as before, we end up with the system of equations

$$\begin{aligned} \phi_x &= \frac{b\psi_x + c\psi_y}{\sqrt{b^2 - ac}} \\ \phi_y &= -\frac{a\psi_x + b\psi_y}{\sqrt{b^2 - ac}}, \end{aligned}$$

or equivalently

$$\begin{cases} \phi_y = -\frac{b}{c}\phi_x + \frac{\sqrt{b^2 - ac}}{c}\psi_x \\ \psi_y = \frac{\sqrt{b^2 - ac}}{c}\phi_x - \frac{b}{c}\psi_x. \end{cases}$$

Section 7 shows that we can solve this ("hyperbolic") system.

To obtain the normal form (H'), we start with v satisfying an equation of the normal form (H),

$$v_{\xi\xi} - v_{\eta\eta} + \cdots = 0,$$

and define

$$(2) \quad w(\rho, \sigma) = v\left(\frac{\rho + \sigma}{2}, \frac{\rho - \sigma}{2}\right).$$

As in the proof of Proposition 5, we find that w satisfies an equation of the normal form (H').

SECOND PROOF. We can instead try for the normal form (H') directly; the normal form (H) is then obtained by the same change of coordinates used in (2), which is equal to its own inverse, up to a factor of 2. So it suffices to find (ϕ, ψ) so that in equation (VII) we have $\alpha = \gamma = 0$; thus we need

$$(1) \quad \begin{cases} a\phi_x^2 + 2b\phi_x\phi_y + c\phi_y^2 = 0 \\ a\psi_x^2 + 2b\psi_x\psi_y + c\psi_y^2 = 0 \end{cases}$$

and

$$(2) \quad \phi_x \psi_y - \phi_y \psi_x \neq 0.$$

As in the previous proof, we can assume that $c(x_0, y_0) \neq 0$. If there is any hope of solving (1) and (2), we clearly must have $\phi_x, \psi_x \neq 0$. This suggests that we look at the equations

$$(1') \quad \begin{cases} a + 2b \left(\frac{\phi_y}{\phi_x} \right) + c \left(\frac{\phi_y}{\phi_x} \right)^2 = 0 \\ a + 2b \left(\frac{\psi_y}{\psi_x} \right) + c \left(\frac{\psi_y}{\psi_x} \right)^2 = 0 \end{cases}$$

$$(2') \quad \frac{\phi_y}{\phi_x} \neq \frac{\psi_y}{\psi_x}.$$

Clearly (1') and (2') imply (1) and (2). Now $ac - b^2 < 0$, so the equation

$$(3) \quad a(x, y) + 2b(x, y)\mu + c(x, y)\mu^2 = 0 \quad c(x, y) \neq 0$$

always has two *distinct, real* roots, $\mu_1(x, y)$ and $\mu_2(x, y)$, varying continuously with (x, y) . So we just have to find ϕ and ψ satisfying

$$(4) \quad \begin{cases} \phi_y - \mu_1 \phi_x = 0 & \phi_x \neq 0 \text{ at } (x_0, y_0) \\ \psi_y - \mu_2 \psi_x = 0 & \psi_x \neq 0 \text{ at } (x_0, y_0), \end{cases}$$

in order for (1') and (2') to hold. But the two equations in (4) are each linear first order PDE's, and the line $y = y_0$ is free, for any given initial conditions $\phi(x, y_0)$ and $\psi(x, y_0)$; in particular, we can assure that $\phi_y(x_0, y_0), \psi_y(x_0, y_0) \neq 0$. ♦

Finally, there is no problem in the parabolic case.

8. THEOREM. Suppose that the equation

$$(I) \quad a(x, y)u_{xx} + 2b(x, y)u_{xy} + c(x, y)u_{yy} + \cdots = 0$$

is parabolic in a neighborhood of (x_0, y_0) . Then there is a differentiable map (ϕ, ψ) from a neighborhood of (x_0, y_0) into \mathbb{R}^2 , with differentiable inverse, having the property that if v is defined by

$$(V) \quad u(x, y) = v(\phi(x, y), \psi(x, y)),$$

then u satisfies (I) if and only if v satisfies a certain equation in the normal form (P).

PROOF. It obviously suffices to find (ϕ, ψ) with $\phi_x \psi_y - \phi_y \psi_x \neq 0$ so that in equation (VII) we have $\gamma = 0$. For then β must be 0 by (VIII), while the last part of (VII) shows that α cannot be zero. We thus want

$$(I) \quad a\psi_x^2 + 2b\psi_x\psi_y + c\psi_y^2 = 0.$$

We obviously must have $a(x_0, y_0) \neq 0$ or $c(x_0, y_0) \neq 0$, say the latter. It suffices to find ψ with $\psi_x(x_0, y_0) \neq 0$ and

$$(I') \quad a + 2b \left(\frac{\psi_y}{\psi_x} \right) + c \left(\frac{\psi_y}{\psi_x} \right)^2 = 0$$

in a neighborhood of (x_0, y_0) ; for we can then take $\phi(x, y) = x$, and $(\phi_x \psi_y - \phi_y \psi_x)(x_0, y_0) = \psi_y(x_0, y_0) \neq 0$. But equation (I') is simply equivalent to

$$\frac{\psi_y}{\psi_x} = -\frac{b}{c} \quad \text{or} \quad c\psi_x = -b\psi_y.$$

This is a first order linear PDE, and the line $y = y_0$ is free near (x_0, y_0) , since $c(x_0, y_0) \neq 0$. So we can find a solution with arbitrary values of $\psi(x, y_0)$ for x near x_0 , in particular with $\psi_x(x_0, y_0) \neq 0$.

If $c(x_0, y_0) = 0$, we look at ψ_x/ψ_y instead. ♦

There is an especially important characterization of elliptic semi-linear PDE's

$$(I) \quad a(x, y)u_{xx} + 2b(x, y)u_{xy} + c(x, y)u_{yy} + \cdots = 0,$$

which is the basis for extending the definition of ellipticity to more general equations. Consider an initial curve c in \mathbb{R}^2 . According to the definitions of section 2, when we are considering the PDE (I), the curve c is free if and only if

$$av_1^2 + 2bv_1v_2 + cv_2^2 \neq 0 \quad \text{on } c$$

(the initial conditions are irrelevant in the semi-linear case). Now if $ac - b^2 > 0$, then the equation

$$0 = a\lambda^2 + 2b\lambda\mu + c\mu^2$$

has no real roots at all, except $\lambda = \mu = 0$. So if (I) is elliptic, then *any* initial curve c is free for any initial conditions. On the other hand, if (I) is hyperbolic, then there is a 2-parameter family of characteristic curves which fail to be free at all points.

For a general second order equation

$$(I) \quad F(x, y, u, p, q, r, s, t) = 0,$$

we define a given solution u to be **elliptic** if

$$4F_r F_t - F_s^2 > 0$$

at all points

$$(x, y, u(x, y), u_x(x, y), u_y(x, y), u_{xx}(x, y), u_{xy}(x, y), u_{yy}(x, y)).$$

In this case, *any* initial curve c is free for the initial data

$$u|_c, \quad u_{x_i}|_c, \quad u_{x_i x_j}|_c.$$

We define a given solution u to be **hyperbolic** or **parabolic** in the obvious analogous way. Notice that for a given PDE which is not semi-linear, and even for a quasi-linear PDE, there may be solutions which are elliptic and also solutions which are hyperbolic or parabolic. The simplest example is the equation

$$u_{xx} + u \cdot u_{yy} = 0.$$

The solution $u = 1$ is elliptic, and the solution $u = -1$ is hyperbolic. This may seem like a ridiculous distinction, but, as we shall learn in sections 8 and 9, solutions near 1 will have entirely different properties from solutions near -1 . A more natural example is the equation

$$(1 - u_x^2)u_{xx} - 2u_x u_y u_{xy} + (1 - u_y^2)u_{yy} = 0,$$

which occurs in gas dynamics. The solution u is elliptic if and only if $u_x^2 + u_y^2 < 1$. Such solutions represent “subsonic” flow, while hyperbolic solutions represent “supersonic” flow. Thus we see that the terms elliptic, hyperbolic, and parabolic, do not make sense for the general second order equation; these terms apply to solutions of the equation, rather than to the equation itself. On the other hand, it clearly makes sense to apply the terms elliptic, hyperbolic, and parabolic to given initial data along a given initial curve.

It is important to observe that the type of a solution remains the same under a change of variable, just as in the semi-linear case. Suppose that u is a solution of

$$(I) \quad F(x, y, u, p, q, r, s, t) = 0,$$

and that we write

$$(V) \quad u(x, y) = v(\phi(x, y), \psi(x, y))$$

for a diffeomorphism (ϕ, ψ) . Using equations (VI), we see that v satisfies an equation

$$(2) \quad G(x, y, v, v_\xi, v_\eta, v_{\xi\xi}, v_{\xi\eta}, v_{\eta\eta}) = 0$$

where G has the form

$$G(—, r, s, t) = F(—, r', s', t')$$

for

$$\begin{aligned} r' &= \phi_x^2 r + 2\phi_x \psi_x s + \psi_x^2 t \\ s' &= \phi_x \phi_y r + (\phi_x \psi_y + \phi_y \psi_x) s + \psi_x \psi_y t \\ t' &= \phi_y^2 r + 2\phi_y \psi_y s + \psi_y^2 t. \end{aligned}$$

Hence

$$G_r = F_r \phi_x^2 + F_s \phi_x \phi_y + F_t \phi_y^2, \quad \text{etc.},$$

and we find that

$$\begin{pmatrix} G_r & \frac{1}{2} G_s \\ \frac{1}{2} G_s & G_t \end{pmatrix} = \begin{pmatrix} \phi_x & \phi_y \\ \psi_x & \psi_y \end{pmatrix} \begin{pmatrix} F_r & \frac{1}{2} F_s \\ \frac{1}{2} F_s & F_t \end{pmatrix} \begin{pmatrix} \phi_x & \psi_x \\ \phi_y & \psi_y \end{pmatrix}.$$

Therefore

$$G_r G_t - \frac{1}{4} G_s^2 = (F_r F_t - \frac{1}{4} F_s^2) \cdot (\phi_x \psi_y - \phi_y \psi_x)^2.$$

Consequently, u is an elliptic or hyperbolic solution of (1) if and only if v is an elliptic or hyperbolic solution of (2).

A few remarks might be made concerning the definitions in higher dimensions (which we do not actually use). A semi-linear PDE

$$\sum_{i,j=1}^n a_{ij}(x_1, \dots, x_n) u_{x_i x_j} + f(x_1, \dots, x_n, u, \dots, u_{x_i}, \dots) = 0$$

is called elliptic at a point $x = (x_1, \dots, x_n)$ if the matrix $(a_{ij}(x))$ is definite, and elliptic in a region if it is elliptic at each point of the region. For an elliptic semi-linear PDE, any initial manifold will be free. We can define several different sorts of hyperbolicity and parabolicity, depending on the rank and signature of this matrix when it is not definite. Proposition 5 generalizes; if the a_{ij} are constants then our equation is equivalent to a normal form

$$u_{x_1 x_1} + \dots + u_{x_r x_r} - u_{x_{r+1} x_{r+1}} - \dots - u_{x_s x_s} + \dots = 0.$$

But Theorems 6–8 do not generalize; there are too many conditions to be satisfied by the diffeomorphism which changes u to v . We can also define when a given solution u of the general second order PDE is elliptic, in a fairly obvious way that is left to the reader.

The fact that any initial curve for an elliptic semi-linear second order equation in 2 variables is free, while a hyperbolic semi-linear equation always has initial curves which are characteristic, certainly suggests that elliptic and hyperbolic equations might have quite different properties. But some of the most important reasons for this classification of second order equations come from physics, which provides the motivation for many of the basic problems about them. So we will first make a brief excursion into this forbidding domain.

6. THE PROTOTYPICAL PDE's OF PHYSICS

We are going to begin by deriving certain classical PDE's which describe important (somewhat idealized) physical situations. The word “derive” had better be taken with a hefty grain of salt, however. What I have really tried to do is give plausible reasons why the physical situations should be governed by those PDE's which the physicists have agreed upon. I've never really been able to understand which parts of the standard derivations are supposed to be obvious, which are mathematically simplifying assumptions, which steps are supposed to correspond to empirically discovered physical laws, or even what all the words are supposed to mean.

The first idealized physical situation which we want to describe is a vibrating string which is not acted upon by any outside forces. We naturally consider this string to be 1-dimensional, and we will assume that the motion actually takes place in a plane. We may regard our string as being either of finite length with fixed endpoints, or of infinite length. The first possibility corresponds to a string stretched between two prongs, while the second is a more idealized conception. We will let $u(x, t)$ denote the height of the string above $(x, 0)$ at time t .

In order to apply the laws of mechanics to the string, we will first regard it as a discrete collection of point masses, whose x -coordinates are all some small distance h apart. In the course of time, the k^{th} particle moves up and

down (but not sideways); its height above the x -axis at time t will be denoted by $u(x_k, t)$. The only forces acting are the “tension” forces between pairs of particles; physically these come about because the motion of the string involves slight changes in the distances between molecules, to which the intermolecular forces are extremely sensitive. We will assume that each particle is acted upon

only by the particle immediately to its left and right. It is thus influenced by two forces, $F_1(x_k, t)$ and $F_{-1}(x_k, t)$, which are vectors pointing along the line from it to its neighboring particles. These vectors make angles of $\theta_1(x_k, t)$ and $\theta_{-1}(x_k, t)$ with the horizontal rays pointing right and left from the position of the particle. Assuming that our particles all have mass m , we use the law $F = ma$ to obtain the following equation for the vertical motion $u(x_k, t)$ of our particle:

$$(a) \quad m \cdot u_{tt}(x_k, t) = |F_1(x_k, t)| \cdot \sin \theta_1(x_k, t) - |F_{-1}(x_k, t)| \cdot \sin \theta_{-1}(x_k, t).$$

Since the particle does not move sideways, we also have

$$(b) \quad 0 = |F_1(x_k, t)| \cdot \cos \theta_1(x_k, t) - |F_{-1}(x_k, t)| \cdot \cos \theta_{-1}(x_k, t).$$

We clearly have

$$(c) \quad \begin{cases} \cos \theta_1(x_k, t) = \frac{h}{\sqrt{h^2 + \{u(x_{k+1}, t) - u(x_k, t)\}^2}} \\ \quad = \frac{1}{\sqrt{1 + D_k^2}}, \quad \text{where } D_k = \frac{u(x_{k+1}, t) - u(x_k, t)}{h}, \\ \sin \theta_1(x_k, t) = \frac{u(x_{k+1}, t) - u(x_k, t)}{h\sqrt{1 + D_k^2}}. \end{cases}$$

Noting that $\theta_{-1}(x_k, t) = \theta_1(x_{k-1}, t)$, we find that (a)–(c) lead to

$$\begin{aligned} (d) \quad & m \cdot u_{tt}(x_k, t) \\ &= |F_1(x_k, t)| \cdot \left[\sin \theta_1(x_k, t) - \sin \theta_{-1}(x_k, t) \cdot \frac{\cos \theta_1(x_k, t)}{\cos \theta_{-1}(x_k, t)} \right] \\ &= |F_1(x_k, t)| \cdot \left[\frac{u(x_{k+1}, t) - u(x_k, t)}{h\sqrt{1 + D_k^2}} - \frac{u(x_k, t) - u(x_{k-1}, t)}{h\sqrt{1 + D_{k-1}^2}} \cdot \frac{\sqrt{1 + D_{k-1}^2}}{\sqrt{1 + D_k^2}} \right] \\ &= \frac{|F_1(x_k, t)|}{\sqrt{1 + D_k^2}} \cdot \left[\frac{u(x_{k+1}, t) + u(x_{k-1}, t) - 2u(x_k, t)}{h} \right]. \end{aligned}$$

This is a system of differential equations for the (possibly infinitely many) functions $u(x_k, t)$. It depends, of course, on knowing F_1 , which would depend on the particular molecular forces involved. Leaving aside that objection for the moment, we now seek a PDE which will describe a uniform string, not a discrete collection. To obtain this, we want to let the number of particles increase, by decreasing h . Of course, we also want to change m in the process, so as not to have an infinitely heavy string at the end. On a piece of thread of length 1, there will be about $1/h$ particles, with a total mass of m/h . So we keep m/h equal to a constant ρ , the **density**. We will also assume that F_1 approaches a function T , the **tension** of the string (it measures with how much force the string will snap apart if it is cut at some point). Now it is well-known (use Taylor's theorem for a proof) that

$$\lim_{h \rightarrow 0} \frac{f(x+h) + f(x-h) - 2f(x)}{h^2} = f''(x).$$

So if we divide equation (d) by h , and then take the limit as $h \rightarrow 0$, we find that $u(x, t)$ should satisfy

$$\rho u_{tt} = \frac{T}{\sqrt{1 + u_x^2}} u_{xx}.$$

Quite apart from the fact that we don't know how to find T , this equation suffers the defect of being non-linear. We can simplify things by restricting ourselves to the case of *small vibrations*; then T is practically constant, and $\sqrt{1 + u_x^2}$ is practically 1. We have thus completed our devious path to the 1-dimensional "wave equation"

$$u_{xx} = \rho u_{tt}.$$

Since $\rho > 0$, a simple change of coordinates always gives us the equation

$$u_{xx} = u_{tt}.$$

This equation also describes sound waves in a long thin pipe; in this case, $u(x, t)$

represents the density of the air at distance x and time t . The 2-dimensional wave equation

$$u_{xx} + u_{yy} = u_{tt}$$

will describe the motion of a vibrating membrane, while the 3-dimensional wave equation

$$u_{xx} + u_{yy} + u_{zz} = u_{tt}$$

will describe sound waves, as well as certain phenomena involving electromagnetic waves. For our purposes, the 1-dimensional wave equation will be quite adequate.

The second idealized physical situation which we want to describe is the temperature distribution within a material body. It is important here to distinguish between the temperature and the heat energy of a body. The **temperature** of a body, which is operationally defined by putting it in contact with a thermometer, is the average kinetic energy of its molecules. We define the temperature $u(x, y, z)$ of a body B at the point (x, y, z) to be the limit of the temperatures of small parts of B which contain (x, y, z) . Naturally this doesn't really make much sense for a physical body made of molecules, so we must deal with an idealized situation when we consider temperature to be a function u defined on a certain subset $B \subset \mathbb{R}^3$.

Heat energy is something different. It takes a certain amount of energy to produce a unit increase in temperature within a unit amount of matter. How much energy depends on the particular kind of matter we have. There are two reasons for this. First of all, the molecules in two different kinds of matter have different weights, so different amounts of energy will be required to increase the average kinetic energy of the same number of molecules by the same amount. In perfect gases, this is the only influencing factor. In other cases, the strength of the intermolecular forces will also influence how much energy has to be put in to increase the average kinetic energy. The **specific heat** or **heat capacitance** C of a piece of matter is the amount of energy required to increase the temperature of a unit mass by a unit amount; we will consider only bodies with uniform specific heat. If $u(x, y, z)$ is the temperature at (x, y, z) of an object B with specific heat C and density ρ , then the total **heat energy** of B is

$$(a) \quad \text{heat energy} = C\rho \int_B u \, dV.$$

The basic experimental fact about heat is that when two bodies of different temperature are placed next to each other, the temperature of the hotter one decreases while the temperature of the cooler one increases, and the rate of change of temperature is proportional to the difference. So if we have two bodies which at each time t have uniform temperatures $T_1(t)$ and $T_2(t)$, then

$$\frac{d}{dt} T_1(t) = (\text{constant}) \cdot (T_1(t) - T_2(t)).$$

This constant will depend on the amount of surface area which the two bodies have in common, as well as on the nature of the material of which they are made. The simplest case to consider is that of a single piece of matter B with

two parts, B_1 and B_2 , initially at different temperatures, T_1 and T_2 . Of course, the two parts will not continue to have uniform temperatures, but at least we

can say that

$$\left. \frac{d}{dt} \right|_{t=0} T_1(t) = (\text{constant}) \cdot A \cdot (T_1(t) - T_2(t)),$$

where A is the area between them. By changing the constant, we can also write this as

$$(b) \quad \left. \frac{d}{dt} \right|_{t=0} C\rho T_1(t) = \kappa \cdot A \cdot (T_1(t) - T_2(t))$$

for some constant κ . This constant κ is called the **heat conductivity** of the matter in question, since it measures the rate at which heat energy is transferred. Roughly speaking, κ must depend on the way the molecules are arranged; this arrangement will somehow determine to what extent faster moving molecules can influence slower moving ones.

Now let us consider a body $B \subset \mathbb{R}^3$ with uniform density ρ , specific heat C , and heat conductivity κ , but with temperature $u(x, y, z, t)$ varying both with position and time. What will be the analogue of equation (b)? The left side of (b) represents the rate of change of the heat energy of the part of B with temperature T_1 . So for any subset $M \subset B$, equation (a) suggests that the analogue of the left side of (b) is

$$(L) \quad \frac{d}{dt} C\rho \int_M u \, dV = C\rho \int_M u_t \, dV.$$

Let us suppose that $M \subset B$ is a 3-dimensional manifold-with-boundary, and

that ν is the outward unit normal on ∂M . If X is the vector field

$$X = \text{grad } u = \left(\frac{\partial u}{\partial x}, \frac{\partial u}{\partial y}, \frac{\partial u}{\partial z} \right) \quad [X \text{ depends on } t],$$

then for fixed t the function $-\langle X, \nu \rangle$ measures how fast the temperature is decreasing as we cross ∂M from the inside to the outside; roughly speaking it measures the difference $T_1 - T_2$ on the two sides of ∂M . So the analogue of

the right side of (b) is

$$(R) \quad (-\kappa) \int_{\partial M} -\langle X, \nu \rangle dA = \kappa \int_{\partial M} \langle X, \nu \rangle dA.$$

Setting (L) = (R), we are led to the equation

$$(c) \quad C\rho \int_M u_t dV = \kappa \int_{\partial M} \langle X, \nu \rangle dA.$$

We could also obtain equation (c) by breaking M up into small cubes, each of which may be regarded as having constant temperature, and applying (b) to each cube; the term on the right of (b) is to be replaced by a sum over the faces of the cube.

Now applying the Divergence Theorem (Problem I.9-13), we are led from equation (c) to

$$(d) \quad \begin{aligned} C\rho \int_M u_t dV &= \kappa \int_M \operatorname{div} X dV \\ &= \kappa \int_M u_{xx} + u_{yy} + u_{zz} dV. \end{aligned}$$

Since this is supposed to hold for all M , the integrands must be equal, and we obtain the 3-dimensional “heat equation”

$$\frac{\kappa}{C\rho} \cdot (u_{xx} + u_{yy} + u_{zz}) = u_t.$$

Of course, we usually replace the positive constant $\kappa/C\rho$ by 1. The 1-dimensional heat equation

$$u_{xx} = u_t$$

describes temperature distribution in a long thin rod, while the 2-dimensional heat equation

$$u_{xx} + u_{yy} = u_t$$

describes temperature distribution in a thin plate.

We obtain a very special equation when we seek the “steady state” temperature distribution of a body. This is the temperature distribution it has when the temperature is *not* varying with time. For example, if we keep both ends of a bar at fixed temperatures by attaching them to “heat reservoirs”, mechanisms which maintain a fixed temperature at a point, then the temperature distribution will rapidly approach a linear function between these two values. To find the steady state temperature distribution, we just set $u_t = 0$ in the heat equation. Thus in

the 1-dimensional case we obtain simply $u_{xx} = 0$, whose solutions are simply linear functions on \mathbb{R} . In the 2- and 3-dimensional cases, we obtain

$$\begin{aligned} u_{xx} + u_{yy} &= 0 && \text{2-dimensional Laplace equation} \\ u_{xx} + u_{yy} + u_{zz} &= 0 && \text{3-dimensional Laplace equation.} \end{aligned}$$

Among these important equations of mathematical physics, we find representatives of each of the three types of second order PDE's. In particular, for two variables we have the following standard examples:

Elliptic equations

$u_{xx} + u_{yy} = 0$	the 2-dimensional Laplace equation
-----------------------	------------------------------------

Hyperbolic equations

$u_{xx} - u_{yy} = 0$	the 1-dimensional wave equation
-----------------------	---------------------------------

The equation $u_{xx}(x, y) = 0$ is a parabolic equation in 2 variables, but obviously a little too simple to be very representative. The standard representative is

Parabolic equations

$u_{xx} = u_y$	the 1-dimensional heat equation
----------------	---------------------------------

Parabolic equations are often slighted in introductory treatments of PDE's, and they will suffer the same treatment in our hands—we will never look at them again. We therefore say good-bye to the heat equation, and consider only the special case of Laplace's equation.

Now let us see what sort of mathematical questions these physical situations suggest. Consider first the 1-dimensional wave equation, which we will write as $u_{xx} - u_{tt} = 0$, to remind us that it describes a process involving time. In such processes, it is naturally of interest to predict what will happen later from a knowledge of what is happening now. It seems perfectly reasonable to hope that we can predict the motion of a string in terms of its initial position and initial velocity,

$$u(x, 0), \quad u_t(x, 0).$$

Moreover, there seems to be no reason why we should have to limit ourselves to analytic initial conditions. For example, if we “pluck” a string, then the simplest description involves an initial condition $u(x, 0)$ which is not even differentiable

everywhere. This example suggests that for *hyperbolic* equations the Cauchy problem is the right one to pose, and that we should not have to restrict ourselves to analytic initial data (which is all we can treat when we rely on the Cauchy-Kowalewski Theorem).

Another mathematical problem is suggested by the fact that in actuality vibrating strings are always secured at two ends. Given two functions $\phi, \psi: [0, L] \rightarrow \mathbb{R}$ with

$$\begin{aligned}\phi(0) &= \phi(L) = 0 \\ \psi(0) &= \psi(L) = 0,\end{aligned}$$

we can ask for a solution u of the 1-dimensional wave equation with

$$\begin{aligned}u(x, 0) &= \phi(x) & 0 \leq x \leq L \\ u_t(x, 0) &= \psi(x) & 0 \leq x \leq L \\ u(0, t) &= u(L, t) = 0 & \text{for all } t.\end{aligned}$$

This is an example of an “initial-boundary value” problem; although such problems are also quite important, we will not consider them at all.

Quite different questions are suggested by Laplace’s equation

$$u_{xx} + u_{yy} + u_{zz} = 0.$$

Here time is not involved at all; the equation describes the steady state heat distribution of some object $B \subset \mathbb{R}^3$. The Cauchy problem for this equation would correspond to the physical problem of predicting the temperature everywhere in B from a knowledge of its values along some plane in B , together with knowledge of its derivative in the perpendicular direction. Now this is hardly a reasonable problem, since it isn’t very easy to measure the temperature at various points inside a solid object. This is the sort of information we would

like to *predict*. The sort of thing we *can* measure is the temperature along the boundary. Similarly, for a region B in \mathbb{R}^2 , we would like to find the solutions u of the 2-dimensional Laplace equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$$

which has given values along the boundary of B . A problem of this sort is called a **Dirichlet problem**. The physics seems to suggest that for elliptic equations it is the Dirichlet problem rather than the Cauchy problem which should be of interest.

Now let us see how these physical speculations correspond to mathematical reality.

The 1-dimensional wave equation

$$(1) \quad u_{xx} - u_{yy} = 0$$

is admirably suited to illustrate the general behavior of hyperbolic equations, because the most general solution of (1) can be written down completely. The trick for doing this is simply to use the alternative standard form for a hyperbolic equation. We define v by

$$(2) \quad v(\xi, \eta) = u\left(\frac{\xi + \eta}{2}, \frac{\xi - \eta}{2}\right) \quad u(x, y) = v(x + y, x - y).$$

Then equation (1) for u gives

$$(3) \quad v_{\xi\eta} = 0.$$

At the very beginning of this chapter we mentioned that the general solution of equation (3) is

$$v(\xi, \eta) = f(\xi) + g(\eta).$$

So the general solution of (1) is

$$(4) \quad \begin{aligned} u(x, y) &= v(x + y, x - y) \\ &= f(x + y) + g(x - y). \end{aligned}$$

If we think of our equation in terms of position x and time t ,

$$u_{xx} - u_{tt} = 0,$$

then the solution

$$u(x, t) = f(x + t) + g(x - t)$$

represents the sum of two “waves”, the first moving to the left as t increases, the second moving to the right.

Using the representation (4) for the solution u of (1), it is easy to find solutions with given initial conditions

$$(5) \quad \begin{cases} u(x, 0) = \phi(x) \\ u_y(x, 0) = \psi(x). \end{cases}$$

Clearly we must have

$$(6) \quad \begin{cases} f(x) + g(x) = \phi(x) \\ f'(x) - g'(x) = \psi(x), \end{cases}$$

and therefore

$$\begin{cases} f'(x) + g'(x) = \phi'(x) \\ f'(x) - g'(x) = \psi(x), \end{cases}$$

which implies

$$f'(x) = \frac{\phi'(x) + \psi(x)}{2}, \quad g'(x) = \frac{\phi'(x) - \psi(x)}{2}.$$

This means that we must have

$$(7) \quad f(x) = \frac{\phi(x)}{2} + \frac{1}{2} \int_0^x \psi(s) ds + C_1, \quad g(x) = \frac{\phi(x)}{2} - \frac{1}{2} \int_0^x \psi(s) ds + C_2$$

for certain constants C_1, C_2 ; and to satisfy (6) we must have $C_1 = -C_2$. Using (4) we then find that u must be

$$(8) \quad u(x, y) = \frac{\phi(x+y) + \phi(x-y)}{2} + \frac{1}{2} \int_{x-y}^{x+y} \psi(s) ds.$$

It is clear, moreover, that this u is a solution of equation (1), with initial conditions (5).

Notice that the boundary values ϕ, ψ enter into the solution in quite a different way than for first order PDE's. If u is a solution of

$$F(x, y, u, p, q) = 0$$

with initial data $\bar{u}, \bar{p}, \bar{q}$ along a free curve σ , then the value $u(x, y)$ of u at a particular point (x, y) depends on the value of the initial data at one point (\bar{x}, \bar{y}) on σ , namely the intersection of σ with the base curve of the characteristic strip through $(x, y, u(x, y), u_x(x, y), u_y(x, y))$. Changing the initial data on an interval which does not contain (\bar{x}, \bar{y}) will not change the value of the solution u at (x, y) . But in the solution (8) of the 1-dimensional wave equation (1), we need to know the values of ϕ and ψ on the whole interval $[x-y, x+y]$ (or $[x+y, x-y]$ if $y < 0$). This interval is therefore called the “domain of dependence” of the point (x, y) .

dence” of the point (x, y) . Conversely, if we are given initial conditions ϕ, ψ

defined only on an interval $[a, b]$, then equation (8) defines u only on the set A of all points (x, y) whose domain of dependence is contained in $[a, b]$. Notice

that A is bounded by the curves through a and b which are characteristic for the PDE (1).

Naturally, we might ask about solutions of (1) along free curves other than the x -axis. In section 8 we will consider this question for even more general hyperbolic equations. If the 1-dimensional wave equation is indeed representative of general hyperbolic equations, then we should be able to solve the Cauchy problem for any hyperbolic equation, along any free curve, and without any assumptions about analyticity of the initial conditions.

The situation is completely different for the 2-dimensional Laplace equation

$$(9) \quad u_{xx} + u_{yy} = 0.$$

Solutions of this equation are called **harmonic** functions (on \mathbb{R}^2), and, as we have pointed out in Chapter 9, their study is closely related to the theory of complex analytic functions. In a simply-connected open subset of \mathbb{R}^2 , every harmonic function u is the real part of a complex analytic function $u + iv$; and conversely, the real part of a complex analytic function is always harmonic. This means, in particular, that *every* solution of (9) is automatically real analytic on \mathbb{R}^2 . So we cannot hope to solve equation (9) with initial conditions

$$(10) \quad \begin{cases} u(x, 0) = \phi(x) \\ u_y(x, 0) = \psi(x) \end{cases}$$

in a neighborhood of the x -axis unless ϕ and ψ are real analytic.* Moreover, if ϕ and ψ are real analytic, then the problem of finding a solution of (9) with initial conditions (10) is essentially trivial. We note that if $u + iv$ is analytic, then

*However, there may be solutions in the upper or lower half-plane.

the Cauchy-Riemann equations give $v_x = -u_y$. So the initial conditions allow us to determine v_x along the x -axis, and therefore determine v up to a constant along the x -axis. So the complex analytic function $u + iv$ is determined up to an imaginary constant on the x -axis, which means that $u + iv$ is determined up to an imaginary constant on the plane.

These remarks really amount to a restatement of the fact, already observed in the proof of the Cauchy-Kowalewski Theorem, that for analytic equations with analytic data, the coefficients of the presumptive analytic solution are easily determined. It is perhaps of interest to note that we can formally solve (9) by analogy with the wave equation (1). If we formally define

$$(11) \quad v(\xi, \eta) = u\left(\frac{\xi + \eta}{2}, \frac{\xi - \eta}{2i}\right) \quad u(x, y) = v(x + iy, x - iy),$$

then equation (9) becomes $v_{\xi\eta} = 0$, which leads us to

$$\begin{aligned} v(\xi, \eta) &= f(\xi) + g(\eta) \\ u(x, y) &= f(x + iy) + g(x - iy). \end{aligned}$$

Taking into account the initial conditions (10), we are led to the formal solution

$$(12) \quad u(x, y) = \frac{\phi(x + iy) + \phi(x - iy)}{2} + \frac{1}{2} \int_{x-iy}^{x+iy} \psi(z) dz.$$

If ϕ and ψ are real analytic, and hence have complex analytic extensions, then this formula makes sense—the integral may be taken along any path from $x - iy$ to $x + iy$. Because ϕ and ψ are real on the real axis, the function u is real-valued, and is easily seen to satisfy (9) and (10).

Our physical considerations suggest that we should be able to solve the Dirichlet problem for (9): given a function $f: \partial B \rightarrow \mathbb{R}$ on the boundary of a region $B \subset \mathbb{R}^2$, we ought to be able to find a solution u of (9) with $u = f$ on ∂B . In complex analysis courses it is shown that this is indeed the case.

7. HYPERBOLIC SYSTEMS IN TWO VARIABLES

In this section we will consider first order quasi-linear systems in two variables. Our initial manifolds for the Cauchy problem will therefore be curves in \mathbb{R}^2 , and we are naturally only interested in initial data for which the initial curve is free. So without loss of generality, we assume that our initial curve is an interval $[a, b]$ of the x -axis, and that our quasi-linear system of n equations

for n unknown functions $u^i: \mathbb{R}^2 \rightarrow \mathbb{R}$ is of the form

$$u_y^i(x, y) = \sum_{j=1}^n a_{ij}(x, y, u^1(x, y), \dots, u^n(x, y)) \cdot u_x^j(x, y) + b^i(x, y, u_1(x, y), \dots, u_n(x, y)).$$

We will often consider $u = (u^1, \dots, u^n)$ to be a column vector, just so that we can multiply on the left by a matrix. Then we can write our system as

$$u_y(x, y) = A(x, y, u(x, y)) \cdot u_x(x, y) + b(x, y, u(x, y))$$

where A is an $n \times n$ matrix of functions, and b is a column vector. More briefly, we have the system

$$u_y = A \cdot u_x + b.$$

This system is called **hyperbolic for given initial conditions** $\overset{\circ}{u} = (\overset{\circ}{u}^1, \dots, \overset{\circ}{u}^n)$ on an interval $[a, b]$ of the x -axis if A is diagonalizable in a neighborhood of all points $(x, 0, \overset{\circ}{u}(x))$ for $x \in [a, b]$; more precisely, it is C^k **hyperbolic** if there is a C^k matrix T such that TAT^{-1} is diagonalizable [this more precise formulation is necessary, because even if A is C^k and always diagonalizable, it may not be possible to choose the diagonalizing matrix T to be C^k]. The basic result is that a quasi-linear system with hyperbolic initial conditions has a solution with these initial conditions; in the next section we will apply this to a single second order equation.

In order to explain the main points of the argument, we will first sketch how the proof would go in the “semi-linear” case,

$$(a) \quad u_y(x, y) = A(x, y)u_x(x, y) + b(x, y, u(x, y)),$$

where A does not depend on u (although b might). Let T be the matrix which diagonalizes A , and define $v = (v^1, \dots, v^n)$ by

$$u(x, y) = T(x, y) \cdot v(x, y),$$

so that

$$u_x = T_x v + T v_x, \quad u_y = T_y v + T v_y.$$

Substituting into (a), we obtain

$$T_y v + T v_y = AT_x v + AT v_x + b,$$

so

$$(b) \quad \begin{aligned} v_y &= (T^{-1}AT)v_x + (T^{-1}AT_x v + T^{-1}b - T^{-1}T_y v) \\ &= Cv_x + d. \end{aligned}$$

Clearly u satisfies (a) with initial conditions $\overset{\circ}{u}$ if and only if v satisfies (b) with initial conditions

$$\overset{\circ}{v}(x) = T^{-1}(x, 0) \cdot \overset{\circ}{u}(x).$$

So we might as well assume that we have the equation

$$(l) \quad u_y = Cu_x + d,$$

where the matrix

$$C(x, y) = \begin{pmatrix} \lambda^1(x, y) & & 0 \\ & \ddots & \\ 0 & & \lambda^n(x, y) \end{pmatrix}$$

is a diagonal matrix. Thus our equation reads

$$(l') \quad -\lambda^i(x, y) \cdot u_x^i + u_y^i = d^i(x, y, u^1(x, y), \dots, u^n(x, y)).$$

The vector field

$$X_i(x, y) = (-\lambda^i(x, y), 1)$$

is called the i^{th} **characteristic vector field** of equation (l'), and the integral curves of X_i are the i^{th} family of **characteristic curves**. We might as well consider only characteristic curves of the form $t \mapsto (c(t), t)$. If u is a solution of (l') and $t \mapsto (c(t), t)$ is a characteristic curve of the i^{th} family, then

$$(2) \quad \begin{aligned} \frac{d}{dt} u^i(c(t), t) &= -\lambda^i(c(t), t) \cdot u_x^i(c(t), t) + u_y^i(c(t), t) \\ &= d^i(c(t), t, u(c(t), t)). \end{aligned}$$

Consequently,

$$(3) \quad u^i(c(\eta), \eta) = u^i(c(0), 0) + \int_0^\eta d^i(c(t), t, u(c(t), t)) dt.$$

In particular, let $t \mapsto (c^i(\xi, \eta), t)$ be the characteristic curve of the i^{th} family which satisfies

$$(4) \quad c^i(\xi, \eta)(\eta) = \xi.$$

If $c^i(\xi, \eta)(0) \in [a, b]$, then equations (3) and (4) give

$$(5) \quad u^i(\xi, \eta) = \bar{u}^i(c^i(\xi, \eta)(0)) + \int_0^\eta d^i(c^i(\xi, \eta)(t), t, u(c^i(\xi, \eta)(t), t)) dt.$$

Conversely, if u satisfies (5) in a region obtained by following all characteristic curves from $[a, b] \times \{0\}$ for a certain time interval in either direction, then u will be a solution of (1') with initial conditions \bar{u} on $[a, b] \times \{0\}$. Equation (5) is something like the integral equation which we solved in Chapter I.5, when we proved that differential equations have solutions, but it is more complicated, because the different components of u are integrated over different curves. Nevertheless, it can be solved in essentially the same way. We define an operator S which takes u to the n -tuple of functions Su given by

$$(Su)^i(\xi, \eta) = \bar{u}^i(c^i(\xi, \eta)(0)) + \int_0^\eta d^i(c^i(\xi, \eta)(t), t, u(c^i(\xi, \eta)(t), t)) dt.$$

Then we show that on a suitable complete space of functions the operator S is a contraction, so that it has a fixed point.

When we look at the quasi-linear system

$$(1) \quad u_y(x, y) = A(x, y, u(x, y)) \cdot u_x(x, y) + b(x, y, u(x, y)),$$

we run into a problem at the very first step. For the matrix T which diagonalizes A will depend on u . If we set

$$\begin{aligned} [T]_x &= \frac{\partial T(x, y, u(x, y))}{\partial x} = T_x + \sum_j T_{u^j} u_x^j \\ [T]_y &= \frac{\partial T(x, y, u(x, y))}{\partial y} = T_y + \sum_j T_{u^j} u_y^j, \end{aligned}$$

then the substitution $u(x, y) = T(x, y, u(x, y)) \cdot v(x, y)$ leads to equation (b) again, except that now T_x and T_y are replaced by $[T]_x$ and $[T]_y$, which involve u ; so we do not even obtain an equation for v . We can reduce our system

to one in diagonal form by means of a somewhat more complicated substitution; however, it will be necessary to assume that the matrix $A(x, y, u(x, y))$ in (1) is invertible [in a neighborhood of the points $(x, 0, \overset{\circ}{u}(x))$].

Suppose we have u satisfying (1), and $T(x, y, u)$ diagonalizes $A(x, y, u)$ for all (x, y, u) in a neighborhood of the points $(x, 0, \overset{\circ}{u}(x))$. Define v by

$$(2) \quad u_y = Tv \quad (\text{i.e., } u_y(x, y) = T(x, y, u(x, y)) \cdot v(x, y)).$$

Then

$$(3) \quad Tv = Au_x + b$$

$$\Downarrow$$

$$(4) \quad u_x = A^{-1}(Tv - b).$$

Differentiating (3) with respect to y , we obtain

$$\begin{aligned} Tv_y + [T]_y v &= Au_{xy} + [A]_y u_x + [b]_y \\ &= A(Tv)_x + [A]_y u_x + [b]_y \quad \text{by (2)} \\ &= A[T]_x v + ATv_x + [A]_y u_x + [b]_y, \end{aligned}$$

so

$$v_y = (T^{-1}AT)v_x + T^{-1}A[T]_x v + T^{-1}[A]_y u_x + T^{-1}[b]_y - T^{-1}[T]_y v.$$

Writing out $[T]_x$, $[A]_y$, \dots , substituting for the u_y from (2) and for the u_x from (4), we obtain

$$\begin{aligned} (5) \quad v_y &= (T^{-1}AT)v_x + T^{-1}A \left[T_x + \sum_j T_{u^j} \{A^{-1}(Tv - b)\}^j \right] v \\ &\quad + T^{-1} \left[A_y + \sum_j A_{u^j} (Tv)^j \right] A^{-1}(Tv - b) \\ &\quad + T^{-1} \left[b_y + \sum_j b_{u^j} (Tv)^j \right] - T^{-1} \left[T_y + \sum_j T_{u^j} (Tv)^j \right] v. \end{aligned}$$

If w is the column vector $u^1, \dots, u^n, v^1, \dots, v^n$, then equations (2) and (5) together can be written in the form

$$w_y = Cw_x + d$$

where C is *diagonal*. We have the initial conditions

$$(6) \quad w(x, 0) = \begin{pmatrix} \overset{\circ}{u}(x) \\ T^{-1}(x, 0, \overset{\circ}{u}(x)) \cdot [A(x, 0, \overset{\circ}{u}(x)) \cdot \overset{\circ}{u}'(x) + b(x, 0, \overset{\circ}{u}(x))] \end{pmatrix}.$$

Note that if A , b and u are C^2 , and A is C^2 diagonalizable, then C and d are C^1 ; if the initial condition $\overset{\circ}{u}$ is C^2 , then the initial condition for w is C^1 . Conversely, we have

9. LEMMA. Let $w = (u^1, \dots, u^n, v^1, \dots, v^n)$ be a C^1 solution of the system (2), (5) with C^1 coefficients C and d and C^1 initial conditions (6). Then u satisfies $u_y = Au_x + b$ (and is C^2).

PROOF. Substituting (2) into the last three terms of (5), multiplying by T , and rearranging, we find that

$$(7) \quad Tv_y + [T]_y v - [b]_y \\ = ATv_x + A \left[T_x + \sum_j T_{u^j} \{A^{-1}(Tv - b)\}^j \right] v + [A]_y A^{-1}(Tv - b).$$

Equation (2) implies that u_y has a continuous partial derivative with respect to x . Hence, by a theorem of calculus, u_x has a continuous first partial derivative with respect to y and $u_{xy} = u_{yx}$. Thus

$$(8) \quad u_{xy} = u_{yx} = (Tv)_x = Tv_x + [T]_x v.$$

Define

$$s = A^{-1}(Tv - b) - u_x.$$

Then s has a continuous first partial derivative with respect to y , and

$$\begin{aligned} s_y &= [A^{-1}]_y(Tv - b) + A^{-1}(Tv_y + [T]_y v - [b]_y) - u_{xy} \\ &= -A^{-1}[A]_y A^{-1}(Tv - b) + A^{-1}(Tv_y + [T]_y v - [b]_y) - u_{xy} \\ &= -A^{-1}[A]_y(s + u_x) + A^{-1}(Tv_y + [T]_y v - [b]_y) - u_{xy}. \end{aligned}$$

Multiplying by A we have

$$\begin{aligned} As_y &= -[A]_y s - [A]_y u_x + (Tv_y + [T]_y v - [b]_y) - Au_{xy} \\ &= -[A]_y s - [A]_y u_x \\ &\quad + ATv_x + A \left[T_x + \sum_j T_{u^j} \{A^{-1}(Tv - b)\}^j \right] v + [A]_y A^{-1}(Tv - b) \\ &\quad - A(Tv_x + [T]_x v) \quad \text{by (7) and (8)} \\ &= -[A]_y s - [A]_y u_x + A \left[T_x + \sum_j T_{u^j} s^j + \sum_j T_{u^j} u_x^j \right] v \\ &\quad + [A]_y(s + u_x) - A[T]_x v \\ &= A \left(\sum_j T_{u^j} s^j \right) v. \end{aligned}$$

Thus

$$s_y = \sum_j (T_{u^j} s^j) v.$$

For fixed x , this is a system of ordinary differential equations. But the initial conditions (6) show that $s^j(x, 0) = 0$. So by uniqueness of solutions, we have $s = 0$, which means that

$$\begin{aligned} Au_x + b &= Tv \\ &= u_y \quad \text{by (2).} \end{aligned}$$

Since v is C^1 , the partial derivative $u_y = Tv$ is C^1 ; hence $u_x = A^{-1}(u_y - b)$ is also C^1 . Thus u is C^2 . ♦

Because of Lemma 9, we now restrict our attention to equations

$$u_y(x, y) = C(x, y, u(x, y)) \cdot u_x(x, y) + d(x, y, u(x, y))$$

where $C(x, y, z)$ is a diagonal $n \times n$ matrix in a neighborhood of the points $(x, 0, \overset{\circ}{u}(x))$. One further simplification is possible. Introduce two new unknowns u^{n+1}, u^{n+2} , and consider the equations

$$\begin{cases} u_y(x, y) = C(u^{n+1}(x, y), u^{n+2}(x, y), u(x, y)) \cdot u_x(x, y) \\ \quad + d(u^{n+1}(x, y), u^{n+2}(x, y), u(x, y)) \\ u_y^{n+1}(x, y) = 0 \\ u_y^{n+2}(x, y) = 1 \end{cases}$$

with the initial conditions

$$\begin{cases} u(x, 0) = \overset{\circ}{u}(x) \\ u^{n+1}(x, 0) = x \\ u^{n+2}(x, 0) = 0. \end{cases}$$

A solution u, u^{n+1}, u^{n+2} of this system clearly gives a solution u of the original equation, with the initial conditions $u(x, 0) = \overset{\circ}{u}$. So we might as well consider an equation of the form

$$(1) \quad u_y(x, y) = C(u(x, y)) \cdot u_x(x, y) + d(u(x, y)),$$

with initial conditions

$$(1_0) \quad u(x, 0) = \overset{\circ}{u}(x),$$

where the matrix $C = \begin{pmatrix} \lambda^1 & & 0 \\ & \ddots & \\ 0 & & \lambda^n \end{pmatrix}$ is a diagonal matrix in a neighborhood of the points $\overset{\circ}{u}(x)$.

Our procedure for solving equation (1) is somewhat more involved than the procedure outlined in the semi-linear case since C now depends on u . For any function u , we define the i^{th} family of **characteristic curves** of u to be the curves $t \mapsto (c(t), t)$ with

$$\frac{dc(t)}{dt} = -\lambda^i(u(c(t), t)).$$

Let $c^i(u; \xi, \eta)$ satisfy this equation and the initial condition

$$c^i(u; \xi, \eta)(\eta) = \xi.$$

As before, we find that if u is a solution of (1), with initial conditions (l_0) , then

$$(2) \quad u^i(\xi, \eta) = \overset{\circ}{u}^i(c^i(u; \xi, \eta)(0)) + \int_0^\eta d^i(u(c^i(u; \xi, \eta)(t), t)) dt.$$

And, conversely, if u satisfies (2), then u will satisfy (1), with initial conditions (l_0) . We are thus led to define an operator S which takes u to the n -tuple of functions Su given by

$$(Su)^i(\xi, \eta) = \overset{\circ}{u}^i(c^i(u; \xi, \eta)(0)) + \int_0^\eta d^i(u(c^i(u; \xi, \eta)(t), t)) dt.$$

The problem is to show that on a suitable complete metric space of functions, the operator S is a contraction; its fixed point will then be a solution of our equation. The proof is carried out in detail in Courant and Lax [1]. It involves a series of estimates that only an analyst could love, and there doesn't seem to be much point reproducing it here, since the paper is readily accessible, and the sane differential geometer would probably skip it anyway. We would simply like to give a precise statement. Let K be a constant such that all $|\lambda^i| \leq K$ on a region containing $[a, b] \times \{0\}$. We consider the region $\Delta(\delta)$ in \mathbb{R}^2 bounded by the lines

$$\begin{aligned} y &= \delta, & y &= -\delta \\ y &= \frac{1}{K}(x - a), & y &= -\frac{1}{K}(x - a) \\ y &= -\frac{1}{K}(x - b), & y &= \frac{1}{K}(x - b) \end{aligned}$$

(then the characteristic curves of a function u will have slopes which are larger than the slopes of the sides of $\Delta(\delta)$; so if a characteristic curve begins in $\Delta(\delta)$, it will stay in $\Delta(\delta)$ until it hits the x -axis).

10. THEOREM. Consider a system, with initial conditions,

$$\begin{aligned} u_y &= Au_x + b \\ u_x(x, 0) &= \overset{\circ}{u}(x) \quad x \in [a, b], \end{aligned}$$

such that either

- (1) the system is semi-linear, A , b , and $\overset{\circ}{u}$ have continuous partial derivatives satisfying a Lipschitz condition, and A is diagonalizable by a matrix T with the same property

or

- (2) the system is quasi-linear, A is invertible, A , b , and $\overset{\circ}{u}$ have continuous second partial derivatives satisfying a Lipschitz condition, and A is diagonalizable by a matrix T with the same property.

Then for sufficiently small $\delta > 0$ (which depends on the constants in the Lipschitz conditions), there is a unique solution of the system in the region $\Delta(\delta)$. In case (1), the solution u has continuous partial derivatives satisfying a Lipschitz condition, and in case (2), the solution u has continuous second partial derivatives satisfying a Lipschitz condition.

We are stating this particular theorem simply because it is the most accessible in the literature. Other approaches allow all sorts of improvements. First of all, the differentiability requirements can be weakened. Second of all, the matrix A need not be invertible even in the quasi-linear case—but then the approach has to be changed considerably. More important, we would like to know that the solutions have a high degree of differentiability if the coefficients and initial conditions do. The proof of this requires considerations like those which are used to prove that the solutions of an ordinary differential equation are differentiable in the initial conditions, considerations which we already omitted in Volume I. We would also like to consider systems depending on parameters, and show that the solutions are differentiable in the parameters; in section 9 we will use this fact. As in the case of ordinary differential equations, differentiability in the parameters is not very hard, and readers may work this out for themselves, guided by Problem I.5-5.

Despite the somewhat unsatisfactory state in which this section ends, I hope the reader will feel fairly convinced that hyperbolic systems have solutions. In the next two sections we will use this fact to show the enormous difference between hyperbolic and elliptic solutions of second order equations.

8. HYPERBOLIC SECOND ORDER EQUATIONS IN TWO VARIABLES

Consider a second order equation

$$(I) \quad 0 = F(x, y, u, u_x, u_y, u_{xx}, u_{xy}, u_{yy}) = F(x, y, u, p, q, r, s, t),$$

an initial curve, and hyperbolic initial data along this curve such that the curve is free for the initial data. As we saw in section 2, by introducing a diffeomorphism of the plane, we can assume that the initial curve is a segment $[a, b]$ of the x -axis. The initial data then amount to functions

$$\overset{\circ}{u}, \overset{\circ}{q}, \overset{\circ}{t}$$

on $[a, b]$ satisfying

$$(I_0) \quad 0 = F(x, 0, \overset{\circ}{u}(x), \overset{\circ}{u}'(x), \overset{\circ}{q}(x), \overset{\circ}{u}''(x), \overset{\circ}{q}'(x), \overset{\circ}{t}(x)),$$

and the initial data will still be hyperbolic,

$$F_s^2 - 4F_r F_t > 0,$$

as we remarked in section 5. Setting

$$\alpha(x) = (x, 0, \overset{\circ}{u}(x), \overset{\circ}{u}'(x), \overset{\circ}{q}(x), \overset{\circ}{u}''(x), \overset{\circ}{q}'(x), \overset{\circ}{t}(x)),$$

the requirement that the initial curve $[a, b] \times \{0\}$ be free means that

$$0 \neq F_t(\alpha(x)), \quad \text{for } x \in [a, b].$$

We claim that we can also assume that $0 \neq F_r(\alpha(x))$. The reason for this is that $F_r = 0$ precisely when the direction of the y -axis is characteristic, and we can always avoid this by an appropriate transformation of the plane. In detail (compare page 53), define a new function v by

$$u(x, y) = v(x + \lambda y, y),$$

where λ is a constant. Note that the map $(x, y) \mapsto (x + \lambda y, y)$ takes the segment $[a, b]$ of the x -axis into itself. Now

$$\begin{array}{ll} u_x = v_x, & u_y = \lambda v_x + v_y \\ u_{xx} = v_{xx} & \\ u_{xy} = \lambda v_{xx} + v_{xy} & \\ u_{yy} = \lambda^2 v_{xx} + 2\lambda v_{xy} + v_{yy} & \end{array} \quad \begin{array}{l} \text{[all partials of } u \text{ evaluated} \\ \text{at } (x, y), \\ \text{all partials of } v \text{ evaluated} \\ \text{at } (x + \lambda y, y)]. \end{array}$$

So equation (I) is equivalent to the equation

$$0 = F(x - \lambda y, y, v, v_x, \lambda v_x + v_y, v_{xx}, \lambda v_{xx} + v_{xy}, \lambda^2 v_{xx} + 2\lambda v_{xy} + v_{yy})$$

[all functions v, \dots, v_{yy} evaluated at (x, y)].

This can be written

$$0 = G(x, y, v, v_x, v_y, v_{xx}, v_{xy}, v_{yy}),$$

where G has the form

$$G(_, r, s, t) = F(_, r, \lambda r + s, \lambda^2 r + 2\lambda s + t).$$

Then we have (leaving out the arguments for convenience)

$$G_r = F_r + \lambda F_s + \lambda^2 F_t.$$

By choosing λ sufficiently large we can insure that $G_r(\alpha(x)) \neq 0$ for all $x \in [a, b]$. So we can assume that $F_r(\alpha(x)), F_t(\alpha(x)) \neq 0$ for $x \in [a, b]$.

One way of treating equation (I) would be to first reduce it to an equivalent one by the considerations of section 2. Since $F_t \neq 0$, there is a function f , defined in a neighborhood of all points

$$\beta(x) = (x, 0, \overset{\circ}{u}(x), \overset{\circ}{u}'(x), \overset{\circ}{q}(x), \overset{\circ}{u}''(x), \overset{\circ}{q}'(x)),$$

such that

$$(a) \quad \overset{\circ}{t}(x) = f(\beta(x))$$

$$(b) \quad F(x, y, u, p, q, r, s, f(x, y, u, p, q, r, s)) = 0.$$

So equation (I) is equivalent to the equation

$$(I') \quad u_{yy} = f(x, y, u, u_x, u_y, u_{xx}, u_{xy}).$$

Differentiating (b) with respect to r and s we obtain

$$0 = F_r + F_t f_r$$

$$0 = F_s + F_t f_s,$$

so we have

$$F_r \neq 0 \implies f_r \neq 0$$

$$F_s^2 - 4F_r F_t > 0 \implies f_s^2 + 4f_r > 0$$

(the latter is nothing more than the condition that the solution u of the equation $f(x, y, u, p, q, r, s) - t = 0$ be hyperbolic).

In section 3 we showed that the Cauchy problem for equation (I') is equivalent to a Cauchy problem for the system

$$\begin{aligned}
 & u_y = v \\
 & \alpha_y = s \\
 & v_y = f(x, y, u, \alpha, v, r, s) \\
 (*) \quad & p_y = v_y \\
 & r_y = s_x \\
 & s_y = f_x + f_u \cdot p + f_\alpha \cdot r + f_v \cdot s + f_r \cdot r_x + f_s \cdot s_x.
 \end{aligned}$$

Setting $\phi = (u, \alpha, v, p, r, s)$, we can write this system as

$$\phi_y = A\phi_x + \psi \quad \text{where} \quad A = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & f_r & f_s & 0 \end{pmatrix}.$$

The eigenvalues of the matrix

$$A = \begin{pmatrix} 0 & 1 \\ f_r & f_s \end{pmatrix}$$

are the roots of $\lambda^2 - f_s\lambda - f_r = 0$, namely

$$\frac{f_s \pm \sqrt{f_s^2 + 4f_r}}{2}.$$

These roots are real and distinct, since $f_s^2 + 4f_r > 0$, and they are $\neq 0$, since $f_r \neq 0$. So A' is diagonalizable, and consequently A is. Theorem 10 then tells us that we can solve the system (*) with the appropriate initial conditions; hence we can solve the original equation (I) with the given hyperbolic initial conditions. The only slight problem is that Theorem 10 was stated only for non-singular A (although, as we mentioned, this requirement is not really necessary). We will therefore give another approach, based on the work of H. Lewy [4], which uses Theorem 10 only as stated, and we will work directly with equation (I), rather than (I'), without assuming that the initial curve is a segment of the x -axis. The new considerations which we will introduce are not only interesting in their own right, but will also be used in the next section.

We are thus considering the second order equation

$$(I) \quad 0 = F(x, y, u, u_x, u_y, u_{xx}, u_{xy}, u_{yy}) = F(x, y, u, p, q, r, s, t),$$

together with an initial curve $c = (c_1, c_2): [a, b] \rightarrow \mathbb{R}^2$ along with initial data $\overset{\circ}{u}, \overset{\circ}{p}, \overset{\circ}{q}, \overset{\circ}{r}, \overset{\circ}{s}, \overset{\circ}{t}: [a, b] \rightarrow \mathbb{R}$ satisfying

$$(I-1) \quad \begin{aligned} 0 &= F(c_1(\tau), c_2(\tau), \overset{\circ}{u}(\tau), \overset{\circ}{p}(\tau), \overset{\circ}{q}(\tau), \overset{\circ}{r}(\tau), \overset{\circ}{s}(\tau), \overset{\circ}{t}(\tau)) \\ &= F(C(\tau)), \quad \text{say.} \end{aligned}$$

In addition, the initial data must satisfy (compare page 34)

$$(I-2) \quad \begin{aligned} \frac{d\overset{\circ}{u}}{d\tau} &= \overset{\circ}{p} \frac{dc_1}{d\tau} + \overset{\circ}{q} \frac{dc_2}{d\tau} \\ \frac{d\overset{\circ}{p}}{d\tau} &= \overset{\circ}{r} \frac{dc_1}{d\tau} + \overset{\circ}{s} \frac{dc_2}{d\tau} \\ \frac{d\overset{\circ}{q}}{d\tau} &= \overset{\circ}{s} \frac{dc_1}{d\tau} + \overset{\circ}{t} \frac{dc_2}{d\tau}. \end{aligned}$$

The fact that the initial data is hyperbolic is expressed by the inequality

$$(I-3) \quad F_s^2 - 4F_r F_t > 0 \quad \text{for all } C(\tau).$$

In section 2 we wrote the condition that c be free as

$$F_r v_1^2 + F_s v_1 v_2 + F_t v_2^2 \neq 0$$

where (v_1, v_2) is a normal at $c(\tau)$ [and F_r, F_s, F_t are evaluated at $C(\tau)$]. If (X, Y) is tangent to c at τ , then the normal is a multiple of $(Y, -X)$, so we can also write this condition as

$$(I-4) \quad F_r Y^2 - F_s XY + F_t X^2 \neq 0.$$

By contrast, the characteristic directions are just those (X, Y) satisfying

$$(I-C) \quad F_r Y^2 - F_s XY + F_t X^2 = 0.$$

Arguments similar to the one given at the beginning of this section show that without loss of generality we can assume that we have $F_r, F_t \neq 0$ at all $C(\tau)$. Now in a neighborhood $\mathcal{U} \subset \mathbb{R}^8$ of $\{C(\tau)\}$ where we have

$$\begin{aligned} F_s^2 - 4F_r F_t &> 0 \\ F_r, F_t &\neq 0 \end{aligned}$$

we can find two continuous everywhere unequal real-valued functions ρ_1, ρ_2 which are solutions of

$$(a) \quad F_r \rho^2 - F_s \rho + F_t = 0.$$

The condition $F_r \neq 0$ guarantees that we have a genuine quadratic equation. The condition $F_t \neq 0$ insures that $\rho_1, \rho_2 \neq 0$, which will be important later on.

Now suppose that we actually have a solution u of (I). Let $\mathcal{V} \subset \mathbb{R}^2$ be $\{(x, y) : (x, y, u(x, y), u_x(x, y), \dots) \in \mathcal{U}\}$. For $R_i = \rho_i(x, y, u(x, y), \dots)$, the two vectors $(1, R_1)$ and $(1, R_2)$ are linearly independent at each point of \mathcal{V} [and equation (I-C) shows that they are always characteristic]. We can now use Proposition I.5-19 to choose an open set $\mathcal{W} \subset \mathbb{R}^2$, with standard coordinates (ξ, η) , say, and a diffeomorphism $\phi: \mathcal{W} \rightarrow \mathcal{V}$ such that

- (i) the parameter curves of ϕ are always characteristic, that is, their tangent vectors are multiples of $(1, R_1)$ or $(1, R_2)$,
- (ii) $\phi(\xi, \xi) = c(\xi)$ for $\xi \in [a, b]$.

Let \mathbf{x} and \mathbf{y} denote the compositions $x \circ \phi$ and $y \circ \phi$, for the standard coordinate system (x, y) on \mathcal{V} . Thus, \mathbf{x} and \mathbf{y} are just the component functions of ϕ . Similarly, let $\mathbf{u} = u \circ \phi$, $\mathbf{p} = p \circ \phi = u_x \circ \phi$, etc. For brevity, if $g: \mathcal{W} \rightarrow \mathbb{R}$ we will use g' to denote the partial derivative $\partial g / \partial \xi$, and g^{\setminus} to denote $\partial g / \partial \eta$. Condition (i) on our map ϕ means that

$$(*1) \quad \rho_1 \mathbf{x}' - \mathbf{y}' = 0$$

$$(*2) \quad \rho_2 \mathbf{x}^{\setminus} - \mathbf{y}^{\setminus} = 0,$$

where ρ_i actually means the function whose value at (ξ, η) is

$$\rho_i(\phi(\xi, \eta), u(\phi(\xi, \eta)), u_x(\phi(\xi, \eta)), \dots) = \rho_i(\mathbf{x}(\xi, \eta), \mathbf{y}(\xi, \eta), \mathbf{u}(\xi, \eta), \mathbf{p}(\xi, \eta), \dots).$$

We also have the general equations

$$(*3) \quad \mathbf{u}' - \mathbf{p}\mathbf{x}' - \mathbf{q}\mathbf{y}' = 0$$

$$(*4) \quad \mathbf{p}' - \mathbf{r}\mathbf{x}' - \mathbf{s}\mathbf{y}' = 0$$

$$(*5) \quad \mathbf{q}' - \mathbf{s}\mathbf{x}' - \mathbf{t}\mathbf{y}' = 0.$$

We obtain further equations as follows. When u is a solution of (I) we have

$$\begin{aligned} 0 &= \frac{\partial F(x, y, u(x, y), \dots)}{\partial x} \\ &= F_x + F_u \cdot u_x + F_p \cdot p_x + F_q \cdot q_x \\ &\quad + F_r \cdot r_x + F_s \cdot s_x + F_t \cdot t_x \\ &= F_r \cdot r_x + F_s \cdot s_x + F_t \cdot t_x + \dots, \end{aligned}$$

where F_x, F_u, F_p, \dots are evaluated at $(x, y, u(x, y), \dots)$. Composing with ϕ , we can write

$$(A) \quad 0 = F_r \cdot (r_x \circ \phi) + F_s \cdot (s_x \circ \phi) + F_t \cdot (t_x \circ \phi) + \{F\}_x,$$

where $\{F\}_x = F_x + F_u \cdot p + F_p \cdot q + F_q \cdot r,$

all partials of F being evaluated at (x, y, u, p, \dots) .

On the other hand, we always have

$$\begin{aligned} r' &= (r_x \circ \phi) \cdot x' + (r_y \circ \phi) \cdot y' \\ s' &= (s_x \circ \phi) \cdot x' + (s_y \circ \phi) \cdot y', \end{aligned}$$

and thus, using equality of mixed partials,

$$(B) \quad \begin{aligned} r' &= (r_x \circ \phi) \cdot x' + (s_x \circ \phi) \cdot y' \\ s' &= (s_x \circ \phi) \cdot x' + (t_x \circ \phi) \cdot y'. \end{aligned}$$

We can write equations (A) and (B) together in matrix form as

$$(C) \quad \begin{pmatrix} x' & y' & 0 \\ 0 & x' & y' \\ F_r & F_s & F_t \end{pmatrix} \cdot \begin{pmatrix} r_x \circ \phi \\ s_x \circ \phi \\ t_x \circ \phi \end{pmatrix} = \begin{pmatrix} r' \\ s' \\ -\{F\}_x \end{pmatrix}.$$

Now

$$\begin{aligned} \det \begin{pmatrix} x' & y' & 0 \\ 0 & x' & y' \\ F_r & F_s & F_t \end{pmatrix} &= (x')^2 F_t - x' y' F_s + (y')^2 F_r \\ &= (x')^2 (F_t - \rho_1 F_s + \rho_1^2 F_r) \quad \text{by } (*1) \\ &= 0, \quad \text{since } \rho_1 \text{ is a solution of (a).} \end{aligned}$$

Consequently

$$\text{rank} \begin{pmatrix} x' & y' & 0 \\ 0 & x' & y' \\ F_r & F_s & F_t \end{pmatrix} \leq 2.$$

Moreover, the last column of the matrix

$$\begin{pmatrix} x' & y' & 0 & r' \\ 0 & x' & y' & s' \\ F_r & F_s & F_t & -\{F\}_x \end{pmatrix}$$

is a linear combination of the first three columns, namely the linear combination $(r_x \circ \phi, s_x \circ \phi, t_x \circ \phi)$, by equation (C), so this matrix also has rank ≤ 2 . Consequently, the determinant of every 3×3 submatrix vanishes. In particular,

$$0 = \det \begin{pmatrix} x' & 0 & r' \\ 0 & y' & s' \\ F_r & F_t & -\{F\}_x \end{pmatrix} = -y' F_r r' - x' F_t s' - x' \{F\}_x y';$$

using (*1) this can be written as follows (note that we don't substitute for the second y'):

$$(*6) \quad \rho_1 F_r r' + F_t s' + \{F\}_x y' = 0.$$

Similarly, we have the following equation, which we will number as

$$(*8) \quad \rho_2 F_r r' + F_t s' + \{F\}_x y' = 0$$

Exactly the same manipulations may be carried out by differentiating with respect to y , instead of x . We have the equation

$$0 = F_r \cdot (r_y \circ \phi) + F_s \cdot (s_y \circ \phi) + F_t \cdot (t_y \circ \phi) + \{F\}_y,$$

together with

$$\begin{aligned} s' &= (r_y \circ \phi) \cdot x' + (s_y \circ \phi) \cdot y' \\ t' &= (s_y \circ \phi) \cdot x' + (t_y \circ \phi) \cdot y', \end{aligned}$$

which we can write as

$$\begin{pmatrix} x' & y' & 0 \\ 0 & x' & y' \\ F_r & F_s & F_t \end{pmatrix} \cdot \begin{pmatrix} r_y \circ \phi \\ s_y \circ \phi \\ t_y \circ \phi \end{pmatrix} = \begin{pmatrix} s' \\ t' \\ -\{F\}_y \end{pmatrix}.$$

So, as before, we have

$$(*7) \quad \rho_1 F_r s' + F_t t' + \{F\}_y y' = 0$$

(as well as an equation involving \cdot).

We have thus selected 8 equations satisfied by the 8 functions x, y, u, p, q, r, s, t when u is a solution of (I):

$$\begin{aligned}
 (*1) \quad & \rho_1 x' - y' = 0 \\
 (*2) \quad & \rho_2 x' - y' = 0 \\
 (*3) \quad & u' - px' - qy' = 0 \\
 (*4) \quad & p' - rx' - sy' = 0 \\
 (*5) \quad & q' - sx' - ty' = 0 \\
 (*6) \quad & \rho_1 F_r r' + F_t s' + (F_x + F_u p + F_p r + F_q s) y' = 0 \\
 (*7) \quad & \rho_1 F_r s' + F_t t' + (F_y + F_u q + F_p s + F_q t) y' = 0 \\
 (*8) \quad & \rho_2 F_r r' + F_t s' + (F_x + F_u p + F_p r + F_q s) y' = 0.
 \end{aligned}$$

We have

$$x(\xi, \xi) = x(\phi(\xi, \xi)) = x(c(\xi)) = c_1(\xi),$$

and similarly for y . And if u has the initial data for (I), then

$$u(\xi, \xi) = u(\phi(\xi, \xi)) = u(c(\xi)) = \overset{\circ}{u}(\xi),$$

and similarly for p, q, \dots . Thus, along the line segment $S = \{(\xi, \xi) : a \leq \xi \leq b\}$ the solutions x, y, u, \dots of (*1)–(*8) have the initial conditions

$$(*0) \quad \begin{cases} x(\xi, \xi) = c_1(\xi), & y(\xi, \xi) = c_2(\xi) \\ u(\xi, \xi) = \overset{\circ}{u}(\xi) \\ p(\xi, \xi) = \overset{\circ}{p}(\xi), & q(\xi, \xi) = \overset{\circ}{q}(\xi) \\ r(\xi, \xi) = \overset{\circ}{r}(\xi), & s(\xi, \xi) = \overset{\circ}{s}(\xi), \quad t(\xi, \xi) = \overset{\circ}{t}(\xi). \end{cases}$$

The beauty of this particular set of 8 equations is the fact that they automatically lead to solutions of equation (I). More precisely, consider 8 functions x, y, u, \dots, t satisfying the system (*), with the initial conditions (*0). We are denoting the 8 unknowns of our system by x, y, u, \dots, t simply for convenience—we are *not* assuming that $D_1 u = p$, etc.

11. LEMMA. Let $c, \overset{\circ}{u}, \overset{\circ}{p}, \overset{\circ}{q}, \overset{\circ}{r}, \overset{\circ}{s}, \overset{\circ}{t} : [a, b] \rightarrow \mathbb{R}$ satisfy (I-1)–(I-4). Suppose that x, y, u, p, q, r, s, t satisfy the system (*), with the initial conditions (*0). Then (x, y) is a coordinate system in a neighborhood of the diagonal line segment $S = \{(\xi, \xi) : a \leq \xi \leq b\}$, and $u \circ (x, y)^{-1}$ is a solution of the PDE (I) with the initial conditions $\overset{\circ}{u}, \overset{\circ}{p}, \overset{\circ}{q}, \overset{\circ}{r}, \overset{\circ}{s}, \overset{\circ}{t}$ on the curve c .

PROOF. Equations (*1) and (*2) show that $(\mathbf{x}', \mathbf{y}')$ and $(\mathbf{x}', \mathbf{y}')$ are characteristic directions, while c' is never characteristic by (I-4). In particular, $c'(\xi)$ is not a multiple of $(\mathbf{x}', \mathbf{y}')(\xi, \xi)$ or $(\mathbf{x}', \mathbf{y}')(\xi, \xi)$.

Our initial conditions on \mathbf{x} and \mathbf{y} give

$$\begin{aligned}\mathbf{x}'(\xi, \xi) + \mathbf{x}'(\xi, \xi) &= c_1'(\xi) \\ \mathbf{y}'(\xi, \xi) + \mathbf{y}'(\xi, \xi) &= c_2'(\xi).\end{aligned}$$

If we had $\mathbf{x}'(\xi, \xi) = 0$ then we would also have $\mathbf{y}'(\xi, \xi) = 0$ by (*1), which would make $(\mathbf{x}', \mathbf{y}')(\xi, \xi) = c'(\xi)$, which we have just noted is not possible. Similarly, we cannot have $\mathbf{x}'(\xi, \xi) = 0$. Thus, the map

$$\phi(\xi, \eta) = (\mathbf{x}(\xi, \eta), \mathbf{y}(\xi, \eta))$$

has Jacobian matrix

$$\begin{pmatrix} \mathbf{x}' & \mathbf{y}' \\ \mathbf{x}' & \mathbf{y}' \end{pmatrix} = \begin{pmatrix} \mathbf{x}' & \rho_1 \mathbf{x}' \\ \mathbf{x}' & \rho_2 \mathbf{x}' \end{pmatrix}$$

with determinant

$$\mathbf{x}' \mathbf{x}' \cdot (\rho_2 - \rho_1) \neq 0 \quad \text{at all points of } S.$$

So $\phi = (\mathbf{x}, \mathbf{y})$ is a coordinate system in a neighborhood of the compact set S .

We next claim that we have

$$(1) \quad 0 = F(\mathbf{x}, \mathbf{y}, \mathbf{u}, \mathbf{p}, \mathbf{q}, \mathbf{r}, \mathbf{s}, \mathbf{t}) \quad [= F(\mathbf{x}(\xi, \eta), \mathbf{y}(\xi, \eta), \mathbf{u}(\xi, \eta), \dots)].$$

To prove this, we add ρ_1 times equation (*7) to (*6), and replace \mathbf{y}' in equation (*6) by $\rho_1 \mathbf{x}'$ [using (*1)]; we thus obtain

$$\begin{aligned}\rho_1^2 F_r s' + \rho_1 F_t t' + \rho_1 (F_y + F_u \mathbf{q} + F_p \mathbf{s} + F_q \mathbf{t}) \mathbf{y}' \\ + \rho_1 F_r \mathbf{r}' + F_t s' + \rho_1 (F_x + F_u \mathbf{p} + F_p \mathbf{r} + F_q \mathbf{s}) \mathbf{x}' = 0.\end{aligned}$$

The coefficient of s' is

$$\rho_1^2 F_r + F_t = \rho_1 F_s,$$

so after dividing by $\rho_1 \neq 0$ we obtain

$$\begin{aligned}0 = F_r \mathbf{r}' + F_s s' + F_t t' + (F_x + F_u \mathbf{p} + F_p \mathbf{r} + F_q \mathbf{s}) \mathbf{x}' \\ + (F_y + F_u \mathbf{q} + F_p \mathbf{s} + F_q \mathbf{t}) \mathbf{y}'.\end{aligned}$$

Making use of (*3)(*5) we then have

$$\begin{aligned} 0 &= F_r r' + F_s s' + F_t t' + F_x x' + F_y y' + F_u u' + F_p p' + F_q q' \\ &= F'. \end{aligned}$$

On the other hand, since $\hat{u}, \hat{p}, \hat{q}, \dots$ are assumed to satisfy (I-2), the initial conditions (*₀) insure that $F = 0$ on the diagonal line segment S . Therefore we have $F = 0$ in a whole neighborhood of this interval.

To prove that $u \circ \phi^{-1} = u \circ (x, y)^{-1}$ is a solution to the equation (I) it thus suffices to prove that

$$p \circ \phi^{-1} = D_1(u \circ \phi^{-1}), \quad q \circ \phi^{-1} = D_2(u \circ \phi^{-1})$$

$$r \circ \phi^{-1} = D_1(p \circ \phi^{-1}), \quad s \circ \phi^{-1} = D_2(p \circ \phi^{-1}), \quad t \circ \phi^{-1} = D_2(q \circ \phi^{-1}).$$

Note that, with our standard notation $\partial/\partial x$ and $\partial/\partial y$ for the coordinate system (x, y) we have

$$D_1(u \circ \phi^{-1}) = \frac{\partial u}{\partial x} \circ \phi^{-1}, \text{ etc.,}$$

so what we have to show amounts to

$$\begin{aligned} p &= \frac{\partial u}{\partial x}, & q &= \frac{\partial u}{\partial y} \\ r &= \frac{\partial p}{\partial x}, & s &= \frac{\partial p}{\partial y}, & t &= \frac{\partial q}{\partial y}. \end{aligned}$$

By our usual chain rule, we have, for any function α ,

$$\begin{aligned} \frac{\partial \alpha}{\partial x} &= \frac{\partial \alpha}{\partial \xi} \cdot \frac{\partial \xi}{\partial x} + \frac{\partial \alpha}{\partial \eta} \cdot \frac{\partial \eta}{\partial x} \\ \frac{\partial \alpha}{\partial y} &= \frac{\partial \alpha}{\partial \xi} \cdot \frac{\partial \xi}{\partial y} + \frac{\partial \alpha}{\partial \eta} \cdot \frac{\partial \eta}{\partial y}, \end{aligned}$$

or, with our abbreviations,

$$\begin{aligned} \frac{\partial \alpha}{\partial x} &= \alpha' \cdot \frac{\partial \xi}{\partial x} + \alpha'' \cdot \frac{\partial \eta}{\partial x} \\ \frac{\partial \alpha}{\partial y} &= \alpha' \cdot \frac{\partial \xi}{\partial y} + \alpha'' \cdot \frac{\partial \eta}{\partial y}. \end{aligned}$$

The partials $\partial\xi/\partial\mathbf{x}, \dots$ are given by

$$\begin{pmatrix} \partial\xi/\partial\mathbf{x} & \partial\xi/\partial\mathbf{y} \\ \partial\eta/\partial\mathbf{x} & \partial\eta/\partial\mathbf{y} \end{pmatrix} = \begin{pmatrix} \mathbf{x}' & \mathbf{x}' \\ \mathbf{y}' & \mathbf{y}' \end{pmatrix}^{-1} = \frac{1}{\mathbf{x}'\mathbf{y}' - \mathbf{x}'\mathbf{y}'} \begin{pmatrix} \mathbf{y}' & -\mathbf{x}' \\ -\mathbf{y}' & \mathbf{x}' \end{pmatrix}.$$

Thus

$$\frac{\partial\alpha}{\partial\mathbf{x}} = \frac{\alpha'\mathbf{y}' - \alpha'\mathbf{y}'}{\mathbf{x}'\mathbf{y}' - \mathbf{x}'\mathbf{y}'}, \quad \frac{\partial\alpha}{\partial\mathbf{y}} = \frac{-\alpha'\mathbf{x}' + \alpha'\mathbf{x}'}{\mathbf{x}'\mathbf{y}' - \mathbf{s}'\mathbf{y}'}.$$

which can be written as

$$\begin{aligned} (2) \quad \mathbf{x}'\alpha' - \mathbf{x}'\alpha' &= \frac{\partial\alpha}{\partial\mathbf{y}}(\mathbf{x}'\mathbf{y}' - \mathbf{x}'\mathbf{y}') \\ \mathbf{y}'\alpha' - \mathbf{y}'\alpha' &= \frac{\partial\alpha}{\partial\mathbf{x}}(\mathbf{y}'\mathbf{x}' - \mathbf{y}'\mathbf{x}'). \end{aligned}$$

Now equations (*6) and (*8) can be written in the form

$$\begin{aligned} \frac{F_r}{\mathbf{x}'}\mathbf{r}' + \frac{F_t}{\mathbf{y}'}\mathbf{s}' + F_x + F_u\mathbf{p} + F_p\mathbf{r} + F_q\mathbf{s} &= 0 \\ \frac{F_r}{\mathbf{x}'}\mathbf{r}' + \frac{F_t}{\mathbf{y}'}\mathbf{s}' + F_x + F_u\mathbf{p} + F_p\mathbf{r} + F_q\mathbf{s} &= 0. \end{aligned}$$

Hence

$$\frac{F_r}{\mathbf{x}'}\mathbf{r}' + \frac{F_t}{\mathbf{y}'}\mathbf{s}' = \frac{F_r}{\mathbf{x}'}\mathbf{r}' + \frac{F_t}{\mathbf{y}'}\mathbf{s}'.$$

Using (2), this equation can be written

$$(3) \quad F_r \frac{\partial\mathbf{r}}{\partial\mathbf{y}} \left(\frac{\mathbf{y}'}{\mathbf{x}'} - \frac{\mathbf{y}'}{\mathbf{x}'} \right) + F_t \frac{\partial\mathbf{s}}{\partial\mathbf{x}} \left(\frac{\mathbf{x}'}{\mathbf{y}'} - \frac{\mathbf{x}'}{\mathbf{y}'} \right) = 0.$$

But

$$\frac{\mathbf{x}'}{\mathbf{y}'} \cdot \frac{\mathbf{x}'}{\mathbf{y}'} = \frac{1}{\rho_1\rho_2} = \frac{F_r}{F_t},$$

so from (3) we obtain the preliminary result

$$(4) \quad \frac{\partial\mathbf{r}}{\partial\mathbf{y}} = \frac{\partial\mathbf{s}}{\partial\mathbf{x}}.$$

Next note that we have

$$\begin{aligned} \mathbf{p}' &= \frac{\partial\mathbf{p}}{\partial\mathbf{x}}\mathbf{x}' + \frac{\partial\mathbf{p}}{\partial\mathbf{y}}\mathbf{y}' && \text{by the chain rule} \\ \mathbf{p}' &= \mathbf{r}\mathbf{x}' + \mathbf{s}\mathbf{y}' && \text{by (*4),} \end{aligned}$$

so that

$$(5) \quad \mathbf{x}' \left(\mathbf{r} - \frac{\partial \mathbf{p}}{\partial \mathbf{x}} \right) = \mathbf{y}' \left(\mathbf{s} - \frac{\partial \mathbf{p}}{\partial \mathbf{y}} \right).$$

On the other hand, the initial conditions $(*_0)$ give

$$\begin{aligned} \frac{d \circ \bar{\mathbf{p}}}{d\xi} &= \frac{d}{d\xi} \mathbf{p}(\xi, \xi) \\ &= \frac{\partial \mathbf{p}}{\partial \mathbf{x}}(\xi, \xi) \frac{d}{d\xi} \mathbf{x}(\xi, \xi) + \frac{\partial \mathbf{p}}{\partial \mathbf{y}}(\xi, \xi) \frac{d}{d\xi} \mathbf{y}(\xi, \xi) \\ &= \frac{\partial \mathbf{p}}{\partial \mathbf{x}}(\xi, \xi) c_1'(\xi) + \frac{\partial \mathbf{p}}{\partial \mathbf{y}}(\xi, \xi) c_2'(\xi), \end{aligned}$$

while the conditions (I-2) imply that

$$\frac{d \circ \bar{\mathbf{p}}}{d\xi} = \mathbf{r}(\xi, \xi) c_1'(\xi) + \mathbf{s}(\xi, \xi) c_2'(\xi),$$

so that

$$(6) \quad c_1'(\xi) \cdot \left[\mathbf{r} - \frac{\partial \mathbf{p}}{\partial \mathbf{x}} \right](\xi, \xi) = c_2'(\xi) \cdot \left[\mathbf{s} - \frac{\partial \mathbf{p}}{\partial \mathbf{y}} \right](\xi, \xi).$$

Equations (5) and (6) together give

$$\begin{pmatrix} c_1'(\xi) & c_2'(\xi) \\ \mathbf{x}'(\xi, \xi) & \mathbf{y}'(\xi, \xi) \end{pmatrix} \begin{pmatrix} \left[\mathbf{r} - \frac{\partial \mathbf{p}}{\partial \mathbf{x}} \right](\xi, \xi) \\ \left[\mathbf{s} - \frac{\partial \mathbf{p}}{\partial \mathbf{y}} \right](\xi, \xi) \end{pmatrix} = 0.$$

Since c' is not a multiple of $(\mathbf{x}', \mathbf{y}')$, as we observed at the beginning of the proof, it follows that we must have

$$\mathbf{r}(\xi, \xi) = \frac{\partial \mathbf{p}}{\partial \mathbf{x}}(\xi, \xi), \quad \mathbf{s}(\xi, \xi) = \frac{\partial \mathbf{p}}{\partial \mathbf{y}}(\xi, \xi).$$

So, if we set

$$P = \mathbf{p}' - \mathbf{r}\mathbf{x}' - \mathbf{s}\mathbf{y}',$$

then $P(\xi, \xi) = 0$. Moreover,

$$P' = \mathbf{p}'' - \mathbf{r}'\mathbf{x}' - \mathbf{s}'\mathbf{y}' - \mathbf{r}\mathbf{x}'' - \mathbf{s}\mathbf{y}'',$$

while equation (*4) gives

$$0 = p'^{\wedge} - r'x' - s'y' - rx'^{\wedge} - sy'^{\wedge}.$$

So we have

$$\begin{aligned} P' &= r'x' - r'x' + s'y' - s'y' \\ &= \left(\frac{\partial s}{\partial x} - \frac{\partial r}{\partial y} \right) (x'y' - x'y') \quad \text{by (2)} \\ &= 0 \quad \text{by (4).} \end{aligned}$$

Consequently, we have

$$(7) \quad 0 = P = p' - rx' - sy'$$

in a neighborhood of S . From (*4) and (7) we have

$$(8) \quad \begin{aligned} x'p' - x'p' &= s(x'y' - x'y') \\ y'p' - y'p' &= r(y'x' - y'x'). \end{aligned}$$

So (2) gives

$$(9) \quad r = \frac{\partial p}{\partial x}, \quad s = \frac{\partial p}{\partial y}.$$

Similarly, set

$$\begin{aligned} U &= u' - px' - qy' \\ Q &= q' - sx' - ty'. \end{aligned}$$

Then we have

$$U = u'^{\wedge} - p'x' - q'y' - px'^{\wedge} - qy'^{\wedge},$$

and

$$0 = u'^{\wedge} - p'x' - q'y' - px'^{\wedge} - qy'^{\wedge} \quad \text{from (*3),}$$

and thus

$$\begin{aligned} (10) \quad U' &= -p'x' - q'y' + p'x' + q'y' \\ &= -s(x'y' - x'y') - q'y' + q'y' \quad \text{by (8)} \\ &= (q' - sx' - ty')y' - (q' - sx' - ty')y' \\ &= Qy' \quad \text{by (*5).} \end{aligned}$$

Likewise,

$$\begin{aligned} Q' &= -s'x' - t'y' + s'x' + t'y' \\ &= \left(\frac{\partial t}{\partial x} - \frac{\partial s}{\partial y} \right) (x'y' - x'y') \quad \text{by (2).} \end{aligned}$$

Now (1) implies, using (9), that

$$0 = \frac{\partial F}{\partial x} = F_x + F_u \frac{\partial u}{\partial x} + F_p r + F_q \frac{\partial q}{\partial x} + F_r \frac{\partial r}{\partial x} + F_s \frac{\partial s}{\partial x} + F_t \frac{\partial t}{\partial x},$$

with a similar equation for $\partial F/\partial y$. Subtract the first of these equations from (*6) and the second from (*7), multiply the resulting equations by x' and y' , respectively, and add them. Taking into account (4), we obtain finally

$$\begin{aligned} &F_t \left(\frac{\partial t}{\partial x} - \frac{\partial s}{\partial y} \right) x' + F_q \left(\frac{\partial q}{\partial x} - s \right) x' + F_u \left(\frac{\partial u}{\partial x} - p \right) x' \\ &\quad - F_t \frac{x'}{y'} \left(\frac{\partial t}{\partial x} - \frac{\partial s}{\partial y} \right) y' + F_q \left(\frac{\partial q}{\partial y} - t \right) y' + F_u \left(\frac{\partial u}{\partial y} - q \right) y' = 0. \end{aligned}$$

Thus we have

$$\begin{aligned} \frac{F_t}{y'} Q' + F_q Q + F_u U &= 0 \\ U' &= Q y'. \end{aligned}$$

Along each line parallel to the ξ -axis, this is simply a system of ordinary differential equations for U and Q . Since $U = Q = 0$ on the diagonal segment S , we find that $U = Q = 0$ in a neighborhood of S . As before,

$$\begin{aligned} U = 0 \text{ and } (*3) &\implies p = \frac{\partial u}{\partial x}, & q = \frac{\partial u}{\partial y}, \\ Q = 0 \text{ and } (*5) &\implies s = \frac{\partial q}{\partial x}, & t = \frac{\partial q}{\partial y}, \end{aligned}$$

and this completes the proof. ♦

Now we want to know whether the system (*) does in fact have a solution with the initial conditions (*₀). We introduce the rotated coordinates (μ, ν) by

$$\begin{aligned}\mu &= \xi + \eta \\ \nu &= \xi - \eta.\end{aligned}$$

Then the segment $S = \{(\xi, \xi) : a \leq \xi \leq b\}$ corresponds to the segment $[2a, 2b]$ of the μ -axis, and

$$\begin{aligned}' &= \frac{\partial}{\partial \mu} + \frac{\partial}{\partial \nu} \\ ' &= \frac{\partial}{\partial \mu} - \frac{\partial}{\partial \nu}.\end{aligned}$$

Denoting x, y, u, \dots, t by ϕ_1, \dots, ϕ_8 , our equations (*1)–(*8) can be written as the following matrix equation, in which each row of the matrix \mathcal{Q} on the right is simply -1 times the corresponding row of the matrix on the left, except for rows 2 and 8, which are equal to $+1$ times the corresponding row [these rows correspond to equations (*2) and (*8) involving $'$]:

$$\begin{bmatrix} \rho_1 & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\ \rho_2 & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\ -p & -q & 1 & 0 & 0 & 0 & 0 & 0 \\ -r & -s & 0 & 1 & 0 & 0 & 0 & 0 \\ -s & -t & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & \{F\}_x & 0 & 0 & 0 & \rho_1 F_r & F_t & 0 \\ 0 & \{F\}_y & 0 & 0 & 0 & 0 & \rho_1 F_r & F_t \\ 0 & \{F\}_x & 0 & 0 & 0 & \rho_2 F_r & F_t & 0 \end{bmatrix} \cdot \begin{bmatrix} \partial \phi_1 / \partial \mu \\ \partial \phi_2 / \partial \mu \\ \partial \phi_3 / \partial \mu \\ \partial \phi_4 / \partial \mu \\ \partial \phi_5 / \partial \mu \\ \partial \phi_6 / \partial \mu \\ \partial \phi_7 / \partial \mu \\ \partial \phi_8 / \partial \mu \end{bmatrix} = \mathcal{Q} \cdot \begin{bmatrix} \partial \phi_1 / \partial \nu \\ \partial \phi_2 / \partial \nu \\ \partial \phi_3 / \partial \nu \\ \partial \phi_4 / \partial \nu \\ \partial \phi_5 / \partial \nu \\ \partial \phi_6 / \partial \nu \\ \partial \phi_7 / \partial \nu \\ \partial \phi_8 / \partial \nu \end{bmatrix}.$$

The determinant of the matrix on the left is easily seen to be

$$(\rho_2 - \rho_1) \det \begin{pmatrix} \rho_1 F_r & F_t & 0 \\ 0 & \rho_1 F_r & F_t \\ \rho_2 F_r & F_t & 0 \end{pmatrix} = (\rho_2 - \rho_1)^2 F_r F_t^2 \neq 0.$$

Writing our equation for short as

$$\mathcal{P} \cdot \phi_\mu = \mathcal{Q} \cdot \phi_\nu,$$

we have

$$\mathcal{Q} = \mathcal{D} \mathcal{P},$$

where \mathcal{D} is the diagonal matrix with -1 's on all diagonals except for $+1$'s at

positions (2, 2) and (8, 8). So we can write our equation as

$$\begin{aligned}\phi_v &= \mathcal{Q}^{-1} \mathcal{P} \phi_\mu \\ &= \mathcal{P}^{-1} \mathcal{D}^{-1} \mathcal{P} \phi_\mu \\ &= \mathcal{P}^{-1} \mathcal{D} \mathcal{P} \phi_\mu.\end{aligned}$$

Since $\mathcal{P}^{-1} \mathcal{D} \mathcal{P}$ is diagonalizable, Theorem 10 shows that we can solve the system (*) uniquely with the initial conditions (*₀). So Lemma 11 shows that our original PDE (I) has a solution with the given initial conditions. We summarize this result in

12. THEOREM. Consider a second order equation

$$F(x, y, u, u_x, u_y, u_{xx}, u_{xy}, u_{yy}) = 0,$$

an initial curve, and hyperbolic initial data along this curve satisfying (I-1) and (I-2), such that the curve is free for the initial data. Suppose that the initial curve, initial data, and F have continuous third partial derivatives satisfying a Lipschitz condition. Then in a neighborhood of this initial curve there is a unique solution with this initial data having continuous second partial derivatives satisfying a Lipschitz condition.

Actually, the hypotheses could be weakened considerably here (partly by weakening the hypotheses in Theorem 10, and even more so by using other methods), but we will not worry about this. More important, we would like to know that the solution u has a high order of differentiability if F , the initial curve, and the initial data do, but we must be content with merely asserting this, since we did not prove this for Theorem 10. One thing is clear, however. Even if F and the initial curve are highly differentiable, or even analytic, there may be solutions u which are far less differentiable. In fact, if we have any hyperbolic initial data, then nearby initial data will also be hyperbolic. We can choose this nearby data to be only C^3 , and then our solution is at most C^3 . As we will see in the next section, this is in marked contrast to the situation for elliptic solutions.

We briefly indicate the situation for the case where our initial curve is everywhere characteristic for the initial data. Assuming, as at the beginning of this section, that the initial curve is a segment $[a, b]$ of the x -axis, the initial data amount to functions

$$\overset{\circ}{u}, \overset{\circ}{q}, \overset{\circ}{t}$$

on $[a, b]$ satisfying

$$(I_0) \quad 0 = F(x, 0, \overset{\circ}{u}(x), \overset{\circ}{u}'(x), \overset{\circ}{q}(x), \overset{\circ}{u}''(x), \overset{\circ}{q}'(x), \overset{\circ}{t}(x)),$$

except that now we have

$$(I_C) \quad 0 = F_t(x, 0, \overset{\circ}{u}(x), \overset{\circ}{u}'(x), \overset{\circ}{q}(x), \overset{\circ}{u}''(x), \overset{\circ}{q}'(x), \overset{\circ}{t}(x)).$$

Differentiating (I_0) and using (I_C) , we find that we must have

$$(**) \quad F_r \overset{\circ}{u}''' + F_s \overset{\circ}{q}'' + (F_x + F_u \overset{\circ}{u}' + F_p \overset{\circ}{u}'' + F_q \overset{\circ}{q}') = 0,$$

and conversely, if $(**)$ and (I_C) are satisfied, and (I_0) holds at one point $(x_0, 0)$, then it holds everywhere on $[a, b]$. By choosing a free curve γ and initial data such that $\gamma(0) = (x_0, 0)$ and the initial data for γ agrees with our initial data along $[a, b]$ at the point $(x_0, 0)$, we can then find a solution having this initial data everywhere on the characteristic curve $[a, b]$.

One particular case will be very important in Chapter 12. We consider an equation

$$(1) \quad 0 = F(x, y, pq, r, s, t) = A(rt - s^2) + Br + Cs + Dt + E \\ = (Ar + D)t + (Br + Cs + E - As^2),$$

where A, \dots, E depend only on x, y, p, q , so that our equation is linear in r, s, t , and $rt - s^2$. Such equations are called "Monge-Ampère equations", and they are the kind we will always encounter. A calculation, using (VI) on page 50, shows that our equation remains a Monge-Ampère equation when we compose with a diffeomorphism of the plane.

Suppose that along the x -axis we have picked $\overset{\circ}{u}$ and $\overset{\circ}{q}$ as the first two functions for our initial data. We can already see if the x -axis is characteristic, because the condition for this is

$$(2) \quad 0 = F_t = Ar + D,$$

which only involves $\overset{\circ}{u}, \overset{\circ}{p} = \overset{\circ}{u}'$, and $\overset{\circ}{q}$ on the x -axis. If equation (2) holds, then there is no hope of selecting $\overset{\circ}{t}$ to complete our initial data unless we also have

$$(3) \quad 0 = Br - Cs + E - As^2$$

along the x -axis. On the other hand, if this equation holds, then any choice of $\overset{\circ}{t}$ will make $\overset{\circ}{u}, \overset{\circ}{q}, \overset{\circ}{t}$ satisfy (1), so if $\overset{\circ}{u}$ and $\overset{\circ}{q}$ satisfy (2) and (3), we can find solutions of (1) with initial data $\overset{\circ}{u}, \overset{\circ}{q}, \overset{\circ}{t}$ for arbitrary functions $\overset{\circ}{t}$.

9. ELLIPTIC SOLUTIONS OF SECOND ORDER EQUATIONS IN TWO VARIABLES

The most important topic in the study of elliptic equations is the Dirichlet problem, and if this were a book on PDE's, it would be inexcusable not to devote a great deal of time to this subject. But we won't say another word about it. Instead, we will consider another aspect of elliptic equations, which often isn't even mentioned in a first course in PDE's. We have already noted that every solution of $u_{xx} + u_{yy} = 0$ is automatically analytic. In this section we will prove that every elliptic solution of any second order equation $F(x, y, u, p, q, r, s, t) = 0$ is likewise analytic, provided of course that F is an analytic function of its arguments. This theorem holds for elliptic solutions of second order PDE's in any number of variables, but the proof we will give works only in the two variable case. This deficiency (which doesn't bother us, since we are interested only in the two variable case) is more than compensated for by its conceptual simplicity. Moreover, the proof, from H. Lewy [5], has one truly beautiful feature—there isn't a single inequality in it.

Since the details of the proof become somewhat complicated, it will probably help to first examine a special case. Consider the equation

$$u_{xx} + u_{yy} = f(x, y, u, p, q),$$

where f is a real analytic function of its arguments. We will show that u can be extended to a complex analytic function from \mathbb{C}^2 to \mathbb{C} ; consequently u must be real analytic.

We recall first that if

$$\alpha(x, y) = \beta(x, y) + i\gamma(x, y)$$

for real-valued β, γ , then the Cauchy-Riemann equations for α are

$$\beta_x = \gamma_y, \quad \beta_y = -\gamma_x;$$

these two equations are equivalent to the single equation

$$(1) \quad \alpha_x = -i\alpha_y.$$

We will rewrite our equation for u as

$$(2) \quad u_{x_1 x_1} + u_{y_1 y_1} = f(x_1, y_1, u, p, q).$$

We denote the two coordinates in \mathbb{R}^2 by x_1, y_1 so that we can consider $\mathbb{R}^2 \subset \mathbb{C}^2$, where \mathbb{C}^2 has coordinates $x = x_1 + ix_2, y = y_1 + iy_2$. Thus we think of u as

a function such that $u(x_1, 0, y_1, 0)$ is defined. We first want to find a complex-valued extension $u(x_1, 0, y_1, y_2)$ of u which is complex analytic in $y_1 + iy_2$. Equation (1) shows that our desired extension should satisfy

$$(3) \quad u_{x_1 x_1} - u_{y_2 y_2} = f(x_1, y_1 + iy_2, u, u_{x_1}, -iu_{y_2})$$

at all points $(x_1, 0, y_1, y_2)$. For each fixed y_1 , consider equation (3) in the (x_1, y_2) -plane, with the initial conditions

$$(4) \quad u(x_1, 0, y_1, 0) = \text{the original } u(x_1, 0, y_1, 0)$$

$$(5) \quad u_{y_2}(x_1, 0, y_1, 0) = i \cdot u_{y_1}(x_1, 0, y_1, 0), \quad \text{for the original } u(x_1, 0, y_1, 0).$$

Equation (3) is hyperbolic. Actually this statement is misleading, for the right side of (3) is already complex-valued, so we have to allow the solution u to be complex-valued; thus we have to consider (3) as an equation for the real and imaginary parts of u . However, if we replace (3) by a system of quasi-linear equations, and make a new system by looking at the real and imaginary parts of all the functions in the old system, then the new system will in fact be hyperbolic. The reader may check this (we will write things out explicitly later on, for the general case). Then Theorem 10 shows* that we really can solve (3) with initial conditions (4) and (5).

Differentiating (5) gives

$$u_{y_2 y_1} = i u_{y_1 y_1} \quad \text{at } (x_1, 0, y_1, 0),$$

while subtracting (3) from (2) gives

$$u_{y_1 y_1} + u_{y_2 y_2} = 0 \quad \text{at } (x_1, 0, y_1, 0).$$

From these two equations we have

$$(6) \quad u_{y_2 y_2} = i u_{y_1 y_2} \quad \text{at } (x_1, 0, y_1, 0).$$

Equations (5) and (6) can also be written

$$(7) \quad \begin{cases} u_{y_1} + i u_{y_2} = 0 \\ \frac{\partial}{\partial y_2}(u_{y_1} + i u_{y_2}) = 0 \end{cases} \quad \text{at } (x_1, 0, y_1, 0).$$

*If we use the system of equations derived in the previous section, then Theorem 10 suffices. If we use the system of equations derived in section 3, then we would need the stronger form of Theorem 10 which allows the matrix A to be singular.

On the other hand, we can also obtain an equation for $\omega = u_{y_1} + iu_{y_2}$. To equation (3) we apply the operator $\nabla = \partial/\partial y_1 + i\partial/\partial y_2$; in the notation of Addendum 1 to Chapter 9, $\frac{1}{2}\nabla u$ would be written $u_{\bar{y}}$. Then we have

$$\begin{aligned}\omega_{x_1 x_1} - \omega_{y_2 y_2} &= \nabla(u_{x_1 x_1} - u_{y_2 y_2}) \\ &= f_y \nabla y + f_u \nabla u + f_p \nabla(u_{x_1}) - i f_q \nabla(u_{y_2}) \\ &\quad \text{since } f \text{ is analytic (compare pg. IV.320)} \\ &= 0 + f_u \omega + f_p \omega_{x_1} - i f_q \omega_{y_2}.\end{aligned}$$

This is a hyperbolic system for ω . Thus (7) implies that $\omega = 0$, by uniqueness of solutions. Hence

$$(8) \quad u_{y_1}(x_1, 0, y_1, y_2) + iu_{y_2}(x_1, 0, y_1, y_2) = 0.$$

Now we will extend u to \mathbb{R}^4 . We do this by considering the equation

$$(9) \quad u_{y_1 y_1} - u_{x_2 x_2} = f(x_1 + ix_2, y, u, -iu_{x_2}, u_{y_2});$$

here x_1 and y_2 are the parameters. We use the initial conditions

$$(10) \quad u(x_1, 0, y_1, y_2) = \text{the } u(x_1, 0, y_1, y_2) \text{ already obtained}$$

$$(11) \quad u_{x_2}(x_1, 0, y_1, y_2) = i \cdot u_{x_1}(x_1, 0, y_1, y_2),$$

for the $u(x_1, 0, y_1, y_2)$ already obtained.

Again we obtain a hyperbolic system, so we can solve (9), with the initial conditions (10) and (11).

Differentiating (11) gives

$$u_{x_1 x_2} = iu_{x_1 x_1} \quad \text{at } (x_1, 0, y_1, y_2),$$

while differentiating (8) with respect to y_1 and y_2 , and then subtracting, gives

$$u_{y_1 y_1} + u_{y_2 y_2} = 0 \quad \text{at } (x_1, 0, y_1, y_2).$$

Finally, subtracting (3) from (9) gives

$$u_{y_1 y_1} + u_{y_2 y_2} - u_{x_1 x_1} - u_{x_2 x_2} = 0 \quad \text{at } (x_1, 0, y_1, y_2).$$

From these three equations we obtain

$$(12) \quad u_{x_2 x_2} = iu_{x_1 x_2} \quad \text{at } (x_1, 0, y_1, y_2).$$

Equations (11) and (12) can be written

$$(13) \quad \begin{cases} u_{x_1} + iu_{x_2} = 0 \\ \frac{\partial}{\partial x_2}(u_{x_1} + iu_{x_2}) = 0 \end{cases} \quad \text{at } (x_1, 0, y_1, y_2).$$

As before, we can also derive an equation for $u_{x_1} + iu_{x_2}$ and conclude that we must have $u_{x_1} + iu_{x_2} = 0$ everywhere. Similarly, we prove that $u_{y_1} + iu_{y_2} = 0$ everywhere. Hence u is complex analytic, and the real-valued solution of the original equation $u_{xx} + u_{yy} = f(x, y, u, p, q)$ is real analytic.

Now we are ready to tackle the general case. We consider an elliptic solution u of a general second order equation

$$0 = F(x, y, u, u_x, u_y, u_{xx}, u_{xy}, u_{yy}) = F(x, y, u, p, q, r, s, t).$$

For convenience, we will often speak as if u were defined on all of \mathbb{R}^2 , although actually the arguments are entirely local. Ellipticity of u means that

$$0 < 4F_r F_t - F_s^2$$

[where F_r, F_s, F_t are evaluated at $(x, y, u(x, y), \dots, u_{yy}(x, y))$], so that, in particular, $F_r, F_t \neq 0$. Let ρ_1, ρ_2 be the two continuous everywhere unequal complex-valued functions which are solutions of

$$F_t - F_s \rho + F_r \rho^2 = 0,$$

and let

$$\begin{aligned} ' &= \frac{\partial}{\partial x} + \rho_1 \frac{\partial}{\partial y} \\ ^\wedge &= \frac{\partial}{\partial x} + \rho_2 \frac{\partial}{\partial y}. \end{aligned}$$

Then we automatically have

$$\begin{aligned} \rho_1 x' - y' &= 0 \\ \rho_2 x^\wedge - y^\wedge &= 0. \end{aligned}$$

Together with the considerations of the previous section we obtain eight equations

$$(*) \quad \begin{cases} \sum_{j=1}^8 a_{ij} \phi_j' = 0 & i = 1, \dots, 6 \\ \sum_{j=1}^8 a_{ij} \phi_j^\wedge = 0 & i = 7, 8, \end{cases}$$

where ϕ_1, \dots, ϕ_8 stand for x, y, u, \dots, t , and the a_{ij} are now complex-valued

functions of ϕ_1, \dots, ϕ_8 . Since F is assumed analytic in all its arguments, the functions a_{ij} are *complex analytic* in some region of \mathbb{C}^2 containing the set $\mathbb{R}^2 \subset \mathbb{C}^2$ where they are defined. We can arrange our equations as in the previous section, with the matrix (a_{ij}) being the matrix \mathcal{P} on page 95.

It will be convenient to use $\xi_1, \xi_2, \eta_1, \eta_2$ as coordinates on \mathbb{R}^4 . Thus we regard the ϕ_j as functions with $\phi_j(\xi_1, 0, \eta_1, 0)$ defined; in particular, we have

$$\begin{aligned} x(\xi_1, 0, \eta_1, 0) &= \phi_1(\xi_1, 0, \eta_1, 0) = \xi_1, \\ y(\xi_1, 0, \eta_1, 0) &= \phi_2(\xi_1, 0, \eta_1, 0) = \eta_1. \end{aligned}$$

The operators $'$ and \backslash in the (ξ_1, η_1) -plane = the (x, y) -plane are then given by

$$(*) \quad \begin{cases} ' = \frac{\partial}{\partial \xi_1} + \rho_1 \frac{\partial}{\partial \eta_1} \\ \backslash = \frac{\partial}{\partial \xi_1} + \rho_2 \frac{\partial}{\partial \eta_1}. \end{cases}$$

We consider the functions a_{ij} as already extended to complex analytic functions of their eight arguments in a suitable region of \mathbb{C}^2 . Now for fixed η_1 , consider equations $(*)$ as equations in the (ξ_1, η_2) -plane, with the operations $'$ and \backslash now being defined by

$$(*) \quad \begin{cases} ' = \frac{\partial}{\partial \xi_1} + \frac{\partial}{\partial \eta_2} \\ \backslash = -\frac{\partial}{\partial \xi_1} + \frac{\partial}{\partial \eta_2}. \end{cases}$$

This is equivalent to taking $\rho_1 = 1$ and $\rho_2 = -1$. So we can write our equations as the matrix equation on page 95, with $\rho_1 = 1$ and $\rho_2 = -1$.

Setting

$$\begin{aligned} \phi_1 &= \psi_1 + i\psi_2 \\ \phi_2 &= \psi_3 + i\psi_4 & \psi_i \text{ real-valued,} \\ &\vdots \end{aligned}$$

and writing our equations in terms of the ψ_i , we obtain a matrix equation

$$\mathbf{P} \cdot \psi_{\eta_2} = \mathbf{Q} \cdot \psi_{\xi_1},$$

with

$$\mathbf{Q} = \mathbf{D}\mathbf{P},$$

where \mathbf{D} is obtained from \mathcal{D} simply by writing each row twice. So by Theorem 10, we can solve (*), with ' and \ given by (*₂); as our initial conditions we just choose

$$\phi_j(\xi_1, 0, \eta_1, 0) = \text{the original } \phi_j(\xi_1, 0, \eta_1, 0).$$

Similarly, we now extend the functions $\phi_j(\xi_1, 0, \eta_1, \eta_2)$ to \mathbb{R}^4 by fixing ξ_1 and η_2 , and considering equations (*) in the (ξ_2, η_1) -plane, with the operations ' and \ now defined by

$$(*)_3 \quad \begin{cases} ' = \frac{\partial}{\partial \xi_2} - \frac{\partial}{\partial \eta_1} \\ \backslash = \frac{\partial}{\partial \xi_2} + \frac{\partial}{\partial \eta_1}. \end{cases}$$

Among the extended functions ϕ_j , we have "x" = ϕ_1 and "y" = ϕ_2 . Since the ϕ_j are now complex-valued, we have four real-valued functions on \mathbb{R}^4 defined by

$$x = x_1 + ix_2, \quad y = y_1 + iy_2.$$

We claim that x_1, x_2, y_1, y_2 is a coordinate system in a neighborhood of any point in the (ξ_1, η_1) -plane. To prove this, we have to compute the Jacobian of (x_1, x_2, y_1, y_2) . First of all, since x_1, x_2, y_1, y_2 are simply $\xi_1, \xi_2, \eta_1, \eta_2$ on the (ξ_1, η_1) -plane, at the point in question we have

$$(1) \quad \begin{cases} \frac{\partial x_1}{\partial \xi_1} = 1, & \frac{\partial x_2}{\partial \xi_1} = 0, & \frac{\partial y_1}{\partial \xi_1} = 0, & \frac{\partial y_2}{\partial \xi_1} = 0 \\ \frac{\partial x_1}{\partial \eta_1} = 0, & \frac{\partial x_2}{\partial \eta_1} = 0, & \frac{\partial y_1}{\partial \eta_1} = 1, & \frac{\partial y_2}{\partial \eta_1} = 0. \end{cases}$$

To compute other derivatives, we first write the two complex-conjugate roots ρ_1, ρ_2 of $F_t - F_s \rho + F_r \rho^2 = 0$ as

$$\rho_1 = \sigma_1 + i\sigma_2, \quad \rho_2 = \sigma_1 - i\sigma_2, \quad \sigma_2 \neq 0.$$

The equations $y' - \rho_1 x' = 0$ and $y\backslash - \rho_2 x\backslash = 0$, with the two different meanings (*₂) and (*₃) for ' and \, give the following equations [after making use of (1)]:

$$(2) \quad \begin{cases} \frac{\partial y_1}{\partial \eta_2} + i \frac{\partial y_2}{\partial \eta_2} - (\sigma_1 + i\sigma_2) \left(1 + \frac{\partial x_1}{\partial \eta_2} + i \frac{\partial x_2}{\partial \eta_2} \right) = 0 \\ \frac{\partial y_1}{\partial \eta_2} + i \frac{\partial y_2}{\partial \eta_2} - (\sigma_1 - i\sigma_2) \left(-1 + \frac{\partial x_1}{\partial \eta_2} + i \frac{\partial x_2}{\partial \eta_2} \right) = 0 \end{cases}$$

$$(3) \quad \begin{cases} \frac{\partial y_1}{\partial \xi_2} + i \frac{\partial y_2}{\partial \xi_2} - 1 - (\sigma_1 + i\sigma_2) \left(\frac{\partial x_1}{\partial \xi_2} + i \frac{\partial x_2}{\partial \xi_2} \right) = 0 \\ \frac{\partial y_1}{\partial \xi_2} + i \frac{\partial y_2}{\partial \xi_2} + 1 - (\sigma_1 - i\sigma_2) \left(\frac{\partial x_1}{\partial \xi_2} + i \frac{\partial x_2}{\partial \xi_2} \right) = 0 \end{cases}$$

Subtracting the first equation of (2) from the second gives

$$\begin{aligned} 2\sigma_1 + 2i\sigma_2 \left(\frac{\partial x_1}{\partial \eta_2} + i \frac{\partial x_2}{\partial \eta_2} \right) = 0 &\implies \frac{\partial x_1}{\partial \eta_2} + i \frac{\partial x_2}{\partial \eta_2} = i \frac{\sigma_1}{\sigma_2} \\ &\implies \frac{\partial x_1}{\partial \eta_2} = 0, \quad \frac{\partial x_2}{\partial \eta_2} = \frac{\sigma_1}{\sigma_2}. \end{aligned}$$

Then we get

$$\begin{aligned} \frac{\partial y_1}{\partial \eta_2} + i \frac{\partial y_2}{\partial \eta_2} &= (\sigma_1 + i\sigma_2) \left(1 + i \frac{\sigma_1}{\sigma_2} \right) = \frac{i(\sigma_1^2 + \sigma_2^2)}{\sigma_2} \\ &\implies \frac{\partial y_1}{\partial \eta_2} = 0, \quad \frac{\partial y_2}{\partial \eta_2} = \frac{\sigma_1^2 + \sigma_2^2}{\sigma_2}. \end{aligned}$$

Similarly, from (3) we get

$$\begin{aligned} 2 + 2i\sigma_2 \left(\frac{\partial x_1}{\partial \xi_2} + i \frac{\partial x_2}{\partial \xi_2} \right) = 0 &\implies \frac{\partial x_1}{\partial \xi_2} + i \frac{\partial x_2}{\partial \xi_2} = \frac{i}{\sigma_2} \\ &\implies \frac{\partial x_1}{\partial \xi_2} = 0, \quad \frac{\partial x_2}{\partial \xi_2} = \frac{1}{\sigma_2}, \end{aligned}$$

and then

$$\begin{aligned} \frac{\partial y_1}{\partial \xi_2} + i \frac{\partial y_2}{\partial \xi_2} &= 1 + (\sigma_1 + i\sigma_2) \frac{i}{\sigma_2} = i \frac{\sigma_1}{\sigma_2} \\ &\implies \frac{\partial y_1}{\partial \xi_2} = 0, \quad \frac{\partial y_2}{\partial \xi_2} = \frac{\sigma_1}{\sigma_2}. \end{aligned}$$

So at the point in question, the matrix of derivatives of x_1, x_2, y_1, y_2 with respect to $\xi_1, \xi_2, \eta_1, \eta_2$ is

$$(4) \quad \begin{array}{c} \begin{matrix} x_1 & x_2 & y_1 & y_2 \end{matrix} \\ \begin{matrix} \xi_1 \\ \xi_2 \\ \eta_1 \\ \eta_2 \end{matrix} \end{array} \begin{pmatrix} 1 & 0 & 0 & 0 \\ 1 & \frac{1}{\sigma_2} & 0 & \frac{\sigma_1}{\sigma_2} \\ 0 & 0 & 1 & 0 \\ 0 & \frac{\sigma_1}{\sigma_2} & 0 & \frac{\sigma_1^2 + \sigma_2^2}{\sigma_2} \end{pmatrix}.$$

The determinant equals 1, so (x_1, x_2, y_1, y_2) is indeed a coordinate system.

Now all partials $\partial/\partial \xi_1, \dots, \partial/\partial \eta_2$ can be written as certain linear combinations of $\partial/\partial x_1, \dots, \partial/\partial y_2$. So we can also write

$$(5) \quad \frac{\partial}{\partial \xi_1} + \frac{\partial}{\partial \eta_2} = A_1 \frac{\partial}{\partial x_1} + B_1 \frac{\partial}{\partial y_1} + C_1 \left(\frac{\partial}{\partial x_1} + i \frac{\partial}{\partial x_2} \right) + D_1 \left(\frac{\partial}{\partial y_1} + i \frac{\partial}{\partial y_2} \right).$$

Now the equation $y' - \rho_1 x' = 0$, where $'$ has the significance $(*_2)$, gives

$$(6) \quad \left(\frac{\partial}{\partial \xi_1} + \frac{\partial}{\partial \eta_2} \right) (y_1 + iy_2) - \rho_1 \left(\frac{\partial}{\partial \xi_1} + \frac{\partial}{\partial \eta_2} \right) (x_1 + ix_2) = 0.$$

But $\partial/\partial x_1 + i\partial/\partial x_2$ gives zero when applied to $x_1 + ix_2$ (or any analytic function of x_1, x_2), and similarly for $\partial/\partial y_1 + i\partial/\partial y_2$. So when we replace the operator $\partial/\partial \xi_1 + \partial/\partial \eta_2$ in equation (6) by its expression in (5) we end up with

$$B_1 - \rho_1 A_1 = 0.$$

Note that if we had $A_1 = 0$, then the operator (5) would not be real unless $C_1 = D_1 = 0$, which is impossible, since $\partial/\partial \xi_1 \neq -\partial/\partial \eta_2$. So $A_1 \neq 0$. Thus we have

$$(7) \quad \frac{\partial}{\partial \xi_1} + \frac{\partial}{\partial \eta_2} = A_1 \frac{\partial}{\partial x_1} + \rho_1 A_1 \frac{\partial}{\partial y_1} + C_1 \left(\frac{\partial}{\partial x_1} + i \frac{\partial}{\partial x_2} \right) + D_1 \left(\frac{\partial}{\partial y_1} + i \frac{\partial}{\partial y_2} \right),$$

and similarly

$$(8) \quad -\frac{\partial}{\partial \xi_1} + \frac{\partial}{\partial \eta_2} = A_2 \frac{\partial}{\partial x_1} + \rho_2 A_2 \frac{\partial}{\partial y_1} + C_2 \left(\frac{\partial}{\partial x_1} + i \frac{\partial}{\partial x_2} \right) + D_2 \left(\frac{\partial}{\partial y_1} + i \frac{\partial}{\partial y_2} \right),$$

$$(9) \quad \frac{\partial}{\partial \xi_2} - \frac{\partial}{\partial \eta_1} = E_1 \frac{\partial}{\partial x_1} + \rho_1 E_1 \frac{\partial}{\partial y_1} + G_1 \left(\frac{\partial}{\partial x_1} + i \frac{\partial}{\partial x_2} \right) + H_1 \left(\frac{\partial}{\partial y_1} + i \frac{\partial}{\partial y_2} \right),$$

$$(10) \quad \frac{\partial}{\partial \xi_2} + \frac{\partial}{\partial \eta_1} = E_2 \frac{\partial}{\partial x_1} + \rho_2 E_2 \frac{\partial}{\partial y_1} + G_2 \left(\frac{\partial}{\partial x_1} + i \frac{\partial}{\partial x_2} \right) + H_2 \left(\frac{\partial}{\partial y_1} + i \frac{\partial}{\partial y_2} \right),$$

where $A_1, A_2, E_1, E_2 \neq 0$. All quantities A_1, \dots, H_2 are simply linear combinations of the derivatives of x_1, x_2, y_1, y_2 with respect to $\xi_1, \xi_2, \eta_1, \eta_2$. For

example, we obviously have

$$\begin{aligned}
 iC_1 &= \left(\frac{\partial}{\partial \xi_1} + \frac{\partial}{\partial \eta_2} \right) x_2, & iD_1 &= \left(\frac{\partial}{\partial \xi_1} + \frac{\partial}{\partial \eta_2} \right) y_2, \\
 iC_2 &= \left(-\frac{\partial}{\partial \xi_1} + \frac{\partial}{\partial \eta_2} \right) x_2, & iD_2 &= \left(-\frac{\partial}{\partial \xi_1} + \frac{\partial}{\partial \eta_2} \right) y_2, \\
 iG_1 &= \left(\frac{\partial}{\partial \xi_2} - \frac{\partial}{\partial \eta_1} \right) x_2, & iH_1 &= \left(\frac{\partial}{\partial \xi_2} - \frac{\partial}{\partial \eta_1} \right) y_2, \\
 iG_2 &= \left(\frac{\partial}{\partial \xi_2} + \frac{\partial}{\partial \eta_1} \right) x_2, & iH_2 &= \left(\frac{\partial}{\partial \xi_2} + \frac{\partial}{\partial \eta_1} \right) y_2.
 \end{aligned}$$

In particular, at a point in the (ξ_1, η_1) -plane we have, from the entries of the matrix (4),

$$\begin{aligned}
 iC_1 &= \frac{\sigma_1}{\sigma_2}, & iD_1 &= \frac{\sigma_1^2 + \sigma_2^2}{\sigma_2}, \\
 iC_2 &= \frac{\sigma_1}{\sigma_2}, & iD_2 &= \frac{\sigma_1^2 + \sigma_2^2}{\sigma_2}, \\
 iG_1 &= \frac{1}{\sigma_2}, & iH_1 &= \frac{\sigma_1}{\sigma_2}, \\
 iG_2 &= \frac{1}{\sigma_2}, & iH_2 &= \frac{\sigma_1}{\sigma_2}.
 \end{aligned}
 \tag{11}$$

Notice that up till now we have used only the two simplest equations of (*). We will now use the whole set. In the initial plane, the equations (*) hold in three different forms, corresponding to the three meanings of the operators ' and ', namely

$$\begin{aligned}
 (*) \quad \left\{ \begin{array}{l} ' = \frac{\partial}{\partial x_1} + \rho_1 \frac{\partial}{\partial y_1} \\ ' = \frac{\partial}{\partial x_1} + \rho_2 \frac{\partial}{\partial y_1} \end{array} \right. & \quad (*) \quad \left\{ \begin{array}{l} ' = \frac{\partial}{\partial \xi_1} + \frac{\partial}{\partial \eta_2} \\ ' = -\frac{\partial}{\partial \xi_1} + \frac{\partial}{\partial \eta_2} \end{array} \right. & \quad (*) \quad \left\{ \begin{array}{l} ' = \frac{\partial}{\partial \xi_2} - \frac{\partial}{\partial \eta_1} \\ ' = \frac{\partial}{\partial \xi_2} + \frac{\partial}{\partial \eta_1} \end{array} \right.
 \end{aligned}$$

From the equations with (*) we have, making use of (7) and (11),

$$\begin{aligned}
 (12) \quad \sum_j a_{ij} \left[A_1 \frac{\partial}{\partial x_1} + \rho_1 A_1 \frac{\partial}{\partial y_1} \right. \\
 \left. + \frac{\sigma_1}{i\sigma_2} \left(\frac{\partial}{\partial x_1} + i \frac{\partial}{\partial x_2} \right) + \frac{\sigma_1^2 + \sigma_2^2}{i\sigma_2} \left(\frac{\partial}{\partial y_1} + i \frac{\partial}{\partial y_2} \right) \right] \phi_j = 0
 \end{aligned}$$

for $i = 1, \dots, 6$. From the equations with $(*_1)$, we have, after multiplying by A_1 ,

$$(13) \quad \sum_j a_{ij} \left[A_1 \frac{\partial}{\partial x_1} + \rho_1 A_1 \frac{\partial}{\partial y_1} \right] \phi_j = 0$$

for $i = 1, \dots, 6$. Subtracting (13) from (12) gives

$$(14) \quad \sum_j a_{ij} \left[\frac{\sigma_1}{i\sigma_2} \left(\frac{\partial}{\partial x_1} + i \frac{\partial}{\partial x_2} \right) + \frac{\sigma_1^2 + \sigma_2^2}{i\sigma_2} \left(\frac{\partial}{\partial y_1} + i \frac{\partial}{\partial y_2} \right) \right] \phi_j = 0.$$

If we do the same thing for $i = 7, 8$, except multiply by A_2 instead of A_1 , we find that (14) holds also for $i = 7, 8$. Since $\det(a_{ij}) \neq 0$, it follows that

$$(15) \quad \left[\frac{\sigma_1}{\sigma_2} \left(\frac{\partial}{\partial x_1} + i \frac{\partial}{\partial x_2} \right) + \frac{\sigma_1^2 + \sigma_2^2}{\sigma_2} \left(\frac{\partial}{\partial y_1} + i \frac{\partial}{\partial y_2} \right) \right] \phi_j = 0 \quad j = 1, \dots, 8.$$

Similarly, if we start from the equations with $(*_3)$, and then subtract the equations with $(*_1)$, multiplied by E_1 and E_2 , we find that

$$(16) \quad \left[\frac{1}{\sigma_2} \left(\frac{\partial}{\partial x_1} + i \frac{\partial}{\partial x_2} \right) + \frac{\sigma_1}{\sigma_2} \left(\frac{\partial}{\partial y_1} + i \frac{\partial}{\partial y_2} \right) \right] \phi_j = 0 \quad j = 1, \dots, 8.$$

For each particular ϕ_j , equations (15) and (16) give two equations for ϕ_j , and since

$$\det \begin{pmatrix} \frac{\sigma_1}{\sigma_2} & \frac{\sigma_1^2 + \sigma_2^2}{\sigma_2} \\ \frac{1}{\sigma_2} & \frac{\sigma_1}{\sigma_2} \end{pmatrix} = -1 \neq 0,$$

we must have

$$(17) \quad \left(\frac{\partial}{\partial x_1} + i \frac{\partial}{\partial x_2} \right) \phi_j = 0 \quad \text{and} \quad \left(\frac{\partial}{\partial y_1} + i \frac{\partial}{\partial y_2} \right) \phi_j = 0.$$

Thus, we see that the Cauchy-Riemann equations for ϕ_j hold in the plane $x_2 = y_2 = 0$.

Now we want to show that the Cauchy-Riemann equations hold for the y_1, y_2 variables. Let

$$\nabla_x = \frac{\partial}{\partial x_1} + i \frac{\partial}{\partial x_2}, \quad \nabla_y = \frac{\partial}{\partial y_1} + i \frac{\partial}{\partial y_2}.$$

We denote the partials of the functions a_{ij} with respect to their 8 variables by $\partial a_{ij} / \partial \phi_l$, etc. Because the a_{ij} are *analytic*, we have

$$\nabla_x a_{ij} = \sum_l \frac{\partial a_{ij}}{\partial \phi_l} \nabla_x \phi_l, \quad \nabla_y a_{ij} = \sum_l \frac{\partial a_{ij}}{\partial \phi_l} \nabla_y \phi_l.$$

Consider the first 6 equations (*), with ' and ` given by (*₂); after division by A_1 they can be written

$$\sum_j a_{ij} \frac{\phi_j'}{A_1} = \sum_j a_{ij} \left[\frac{\partial}{\partial x_1} + \rho_1 \frac{\partial}{\partial y_1} + \frac{C_1}{A_1} \nabla_x + \frac{D_1}{A_1} \nabla_y \right] \phi_j = 0 \quad i = 1, \dots, 6.$$

Apply ∇_x to this equation. Since we have

$$\begin{aligned} \nabla_x \frac{\phi_j'}{A_1} &= \nabla_x \left(\left(\frac{\partial}{\partial x_1} + \rho_1 \frac{\partial}{\partial y_1} + \frac{C_1}{A_1} \nabla_x + \frac{D_1}{A_1} \nabla_y \right) \phi_j \right) \\ &= \left(\frac{\partial}{\partial x_1} + \rho_1 \frac{\partial}{\partial y_1} + \frac{C_1}{A_1} \nabla_x + \frac{D_1}{A_1} \nabla_y \right) \nabla_x \phi_j \\ &\quad + \left(\nabla_x \frac{C_1}{A_1} \right) \cdot \nabla_x \phi_j + \left(\nabla_x \frac{D_1}{A_1} \right) \cdot \nabla_y \phi_j + \frac{\partial \phi_j}{\partial y_1} \sum_{l=1}^8 \frac{\partial \rho_1}{\partial \phi_l} \nabla_x \phi_l \\ &= \frac{1}{A_1} (\nabla_x \phi_j)' + \left(\nabla_x \frac{C_1}{A_1} \right) \cdot \nabla_x \phi_j + \left(\nabla_x \frac{D_1}{A_1} \right) \cdot \nabla_y \phi_j + \frac{\partial \phi_j}{\partial y_1} \sum_{l=1}^8 \frac{\partial \rho_1}{\partial \phi_l} \nabla_x \phi_l, \end{aligned}$$

we obtain an equation of the form

$$(18) \quad \sum_j a_{ij} (\nabla_x \phi_j)' + \sum_j (b_{ij} \nabla_x \phi_j + c_{ij} \nabla_y \phi_j) = 0 \quad i = 1, \dots, 6.$$

Treating the equations for $i = 7, 8$ similarly, except dividing by A_2 , we obtain

$$(19) \quad \sum_j a_{ij} (\nabla_x \phi_j)' + \sum_j (b_{ij} \nabla_x \phi_j + c_{ij} \nabla_y \phi_j) = 0 \quad i = 7, 8.$$

Applying ∇_y similarly to these same equations, we obtain

$$(20) \quad \sum_j a_{ij} (\nabla_y \phi_j)' + \sum_j (d_{ij} \nabla_x \phi_j + e_{ij} \nabla_y \phi_j) = 0 \quad i = 1, \dots, 6$$

$$(21) \quad \sum_j a_{ij} (\nabla_y \phi_j)' + \sum_j (d_{ij} \nabla_x \phi_j + e_{ij} \nabla_y \phi_j) = 0 \quad i = 7, 8.$$

Equations (18)–(21) are 16 equations for 16 complex-valued functions $\nabla_x \phi_j$, $\nabla_y \phi_j$. The matrix of the system is

$$\begin{pmatrix} (a_{ik}) & 0 \\ 0 & (a_{ik}) \end{pmatrix}.$$

So we easily see that the corresponding system of 32 equations for 32 real-valued functions is hyperbolic. But we know from (17) that $\nabla_x \phi_j = \nabla_y \phi_j = 0$ for $\eta_2 = 0$. By uniqueness of solutions, it follows that $\nabla_x \phi_j = \nabla_y \phi_j$ for all $(\xi_1, 0, \eta_1, \eta_2)$.

In exactly the same way, we show finally that $\nabla_x \phi_j = \nabla_y \phi_j = 0$ for all $(\xi_1, \xi_2, \eta_1, \eta_2)$. Thus all extended ϕ_j , in particular $u = \phi_3$, are complex analytic. So the original real solution u of our equation is real analytic.

In this proof we need the ϕ_j to have continuous second partial derivatives satisfying a Lipschitz condition (so that the $\nabla_x \phi_j, \nabla_y \phi_j$ in the last step will have continuous partials satisfying a Lipschitz condition). Thus we require u to have continuous fourth partial derivatives satisfying a Lipschitz condition. Actually, the result holds even if u is C^3 , but that information comes out of other proofs (it might also be derivable from the present proof with enough extra work). We will merely state this stronger result in the summary of all the work of this section:

13. THEOREM. If u is a C^3 elliptic solution of the equation

$$F(x, y, u, u_x, u_y, u_{xx}, u_{xy}, u_{yy}) = 0,$$

where F is a real analytic function of its 8 arguments, then u is real analytic.

ADDENDUM 1

DIFFERENTIAL SYSTEMS;
THE CARTAN-KÄHLER THEOREM

Suppose we are given everywhere linearly independent 1-forms $\omega_1, \dots, \omega_l$ on an n -manifold M . The Frobenius integrability theorem, in the differential form version (Proposition I.7-14), tells us when every point $p \in M$ lies in some $(n-l)$ -dimensional manifold $N \subset M$ such that all ω_j restricted to N are zero: this happens if and only if each $d\omega_j$ is in the ideal generated by the $\{\omega_j\}$. Our proof rested on the observation that the $d\omega_j$ have this property if and only if the $(n-l)$ -dimensional distribution $\Delta = \bigcap_k \ker \omega_j$ has the property that $[X, Y]$ belongs to Δ whenever X and Y do. On the other hand, simple direct considerations could have shown us that the condition on the $d\omega_j$ is certainly necessary. For suppose that $N \subset M$ is an $(n-l)$ -dimensional submanifold of M on which all ω_j vanish (i.e., $i^*\omega_j = 0$, where $i: N \rightarrow M$ is the inclusion map). Then the $d\omega_j$ also vanish on N , since

$$i^*(d\omega_j) = d(i^*\omega_j) = 0.$$

But the 2-forms $\omega_j \wedge \omega_k$ also vanish on N , and because the ω_j are everywhere linearly independent, at each point $p \in N$ the $\{\omega_j(p) \wedge \omega_k(p)\}$ already span the set of all elements of $\Omega^2(M_p)$ which vanish on N_p . Thus $d\omega_j(p)$ must be a linear combination of the $\{\omega_j(p) \wedge \omega_k(p)\}$.

We could also have given a direct proof that this necessary condition is sufficient, without appealing to the first version of the Frobenius integrability theorem. We will briefly outline this proof, for it not only shows just how the condition on the $d\omega_i$ is related to the classical integrability criterion, but it is also similar in approach to the proof of the main theorem which we will be proving later.

For convenience we set $k = n - l$, and number our forms as $\omega_{k+1}, \dots, \omega_n$. Since the result is essentially local, we can assume that $M = \mathbb{R}^n$, that the point $p \in M$ in question is $0 \in \mathbb{R}^n$, and, by changing our axes if necessary, that $dx^1, \dots, dx^k, \omega_{k+1}, \dots, \omega_n$ span $(\mathbb{R}_0^n)^*$. This means that near 0 we can write

$$(1) \quad dx^\rho = \sum_{h=1}^k A_{h\rho} dx^h + \sum_{r=k+1}^n B_{r\rho} \omega_r \quad \rho = k+1, \dots, n.$$

Now take d of equation (1), and consider the coefficient of a term $dx^i \wedge dx^j$ ($i < j \leq k$), when the right side is expressed in terms of the 2-forms

$$dx^i \wedge dx^j, \quad dx^i \wedge \omega_r, \quad \omega_r \wedge \omega_s,$$

which are linearly independent near 0. When we write $d\omega_r$ in this way, the coefficients of $dx^i \wedge dx^j$ must vanish, since by hypothesis $d\omega_r$ is in the ideal generated by the ω_r . So we obtain

$$\begin{aligned}
 0 &= \text{coefficient of } dx^i \wedge dx^j \text{ in } \sum_{h=1}^k dA_{h\rho} \wedge dx^h \\
 &= \text{coefficient of } dx^i \wedge dx^j \text{ in } \sum_{h=1}^k \sum_{\sigma=1}^n \frac{\partial A_{h\rho}}{\partial x^\sigma} dx^\sigma \wedge dx^h \\
 &= \frac{\partial A_{j\rho}}{\partial x^i} - \frac{\partial A_{i\rho}}{\partial x^j} \\
 &\quad + \text{coefficient of } dx^i \wedge dx^j \text{ in } \sum_{h=1}^k \sum_{\sigma=k+1}^n \sum_{t=1}^k \frac{\partial A_{h\rho}}{\partial x^\sigma} A_{t\sigma} dx^t \wedge dx^h \\
 &\quad \text{by (1)}
 \end{aligned}$$

and thus, finally,

$$(2) \quad 0 = \frac{\partial A_{j\rho}}{\partial x^i} - \frac{\partial A_{i\rho}}{\partial x^j} + \sum_{\sigma=k+1}^n \frac{\partial A_{j\rho}}{\partial x^\sigma} A_{i\sigma} - \sum_{\sigma=k+1}^n \frac{\partial A_{i\rho}}{\partial x^\sigma} A_{j\sigma}.$$

But now the classical integrability result (Theorem I.6-1) shows that we can find functions f^{k+1}, \dots, f^n in a neighborhood of 0 in \mathbb{R}^k such that

$$(3) \quad \frac{\partial f^\rho}{\partial x^h}(x_1, \dots, x_k) = A_{h\rho}(x_1, \dots, x_k, f^{k+1}(x_1, \dots, x_k), \dots, f^n(x_1, \dots, x_k)).$$

Equation (3) is precisely the condition that the ω_r vanish on the submanifold $\{(x_1, \dots, x_k, f^{k+1}(x_1, \dots, x_k), \dots, f^n(x_1, \dots, x_k))\}$, so the proof is complete.

Now we want to consider a more general question. Suppose we are given an ideal \mathfrak{d} of differential forms on M , not necessarily generated by 1-forms, which satisfies $d\mathfrak{d} \subset \mathfrak{d}$. When is there a submanifold $N \subset M$ such that all forms of \mathfrak{d} vanish on N ? We warn right away that everything is going to be much more complicated. The basic information regarding this situation is contained in the Cartan-Kähler theorem (first proved by Cartan when \mathfrak{d} is generated by 1-forms and 2-forms, and then generalized by Kähler). We will never use this result, except to give an alternative proof of a theorem, in the Addendum to Chapter 11, but I felt that it should be included here, not only because it is an application of the Cauchy-Kowalewski theorem, but also because it plays such a crucial role in the work of É. Cartan. It enables one to say, in a sense that will

be clarified later on, “how many” different submanifolds of \mathbb{R}^n satisfy a given geometric condition, e.g., the condition that H is constant [here we are considering the *local* theory of submanifolds, without any completeness requirements]; numerous such examples are worked out in É. Cartan {2}. The Cartan-Kähler theorem may be thought of as a result about integrability conditions for systems of partial differential equations, of a more complex type than (3). Nevertheless, the systems to be considered are still very special, since they come from differential forms—one could compare this situation with the Poincaré Lemma, which also involves integrability conditions of a very special sort.

Before we can state the Cartan-Kähler theorem, some preliminary definitions will be required. First we want to be more precise about ideals of differential forms. Let $\Omega^k(M)$ be the vector space of all k -forms on M . Then the direct sum $\Omega(M) = \Omega^0(M) \oplus \cdots \oplus \Omega^n(M)$ is a ring under \wedge . For any ideal $\mathcal{I} \subset \Omega(M)$, we set $\mathcal{I}_k = \mathcal{I} \cap \Omega^k(M)$. We will consider only ideals \mathcal{I} which are **homogeneous**, meaning that

$$\mathcal{I} = \mathcal{I}_0 \oplus \mathcal{I}_1 \oplus \cdots \oplus \mathcal{I}_n.$$

Thus, for example, if \mathcal{I} contains $\omega_1 + \omega_2$ where ω_1 is a 1-form and ω_2 is a 2-form, then \mathcal{I} must contain ω_1 and ω_2 (so \mathcal{I} could not be the ideal generated by $\omega_1 + \omega_2$). For a homogeneous ideal \mathcal{I} it is certainly clear what we mean by the condition $d\mathcal{I} \subset \mathcal{I}$: for each k -form $\omega \in \mathcal{I}$, the $(k+1)$ -form $d\omega$ must also be in \mathcal{I} . A homogeneous ideal with this property is called a **differential ideal**, or sometimes a **differential system**. For the present we will assume that our differential system \mathcal{I} does not contain functions, i.e., that $\mathcal{I}_0 = 0$.

Let \mathcal{I} be any homogeneous ideal with $\mathcal{I}_0 = 0$ (not necessarily satisfying $d\mathcal{I} \subset \mathcal{I}$). An l -dimensional submanifold $N \subset M$, with inclusion map $i: N \rightarrow M$, is called an **integral submanifold** of \mathcal{I} if $i^*\omega = 0$ for all forms $\omega \in \mathcal{I}$. It is easy to see that, because \mathcal{I} is an ideal, this condition holds if $i^*\omega = 0$ for all forms $\omega \in \mathcal{I}_l$. It is also easy to see that if \mathcal{I} is generated by a set of elements S , then it suffices to have $i^*\omega = 0$ for all $\omega \in S$ of degree $\leq l$. In order to analyze integral submanifolds of \mathcal{I} , we consider the possible tangent spaces for them. An l -dimensional subspace $W \subset M_p$ of M_p is called an (**l -dimensional**) **integral element** of \mathcal{I} if all $\omega(p)$ are zero when restricted to W , for all $\omega \in \mathcal{I}$; again, it suffices to have this for all $\omega \in \mathcal{I}_l$, or for all ω of degree $\leq l$ in a generating set S . Notice that a subspace of an integral element is also an integral element. We will also allow the 0-dimensional subspace of M_p , which we will identify with p . It is always an integral element, since we are assuming that $\mathcal{I}_0 = 0$.

When the ideal \mathcal{I} is generated by 1-forms, we must assume, for the Frobenius integrability theorem, that locally \mathcal{I} is generated by a fixed number of linearly independent 1-forms. The analogous requirements for an arbitrary differential

system \mathcal{I} are more involved. Let $W \subset M_p$ be a k -dimensional integral element, and let X_1, \dots, X_k be any basis. We define the “polar space”

$$\mathcal{E}(W) = \{X \in M_p : \omega(p)(X_1, \dots, X_k, X) = 0 \text{ for all } \omega \in \mathcal{I}_{k+1}\}.$$

[For $k = 0$, this means that $\mathcal{E}(p) = \{X \in M_p : \omega(p)(X) = 0 \text{ for all } \omega \in \mathcal{I}_1\}$.] This definition is clearly independent of the basis X_1, \dots, X_k , and we have $W \subset \mathcal{E}(W)$. Using the fact that \mathcal{I} is an *ideal*, we easily see that for all $X \in \mathcal{E}(W)$ and all $h \leq k$ we have

$$\omega(p)(X_{i_1}, \dots, X_{i_h}, X) = 0 \quad \text{for all } \omega \in \mathcal{I}_{h+1}.$$

This means that for every $X \in \mathcal{E}(W)$ which is not in W , the space $W \oplus \mathbb{R} \cdot X$ is an extension of W to a $(k + 1)$ -dimensional integral element; conversely, any $(k + 1)$ -dimensional integral element extending W is of this form. We will also find it useful to consider explicitly the ordered bases (X_1, \dots, X_k) of integral elements. Let

$$\begin{aligned} \mathcal{M}_k &= \{(p, X_1, \dots, X_k) : X_1, \dots, X_k \text{ span a} \\ &\quad k\text{-dimensional integral element of } M_p\} \\ &\subset M \times TM \times \dots \times TM. \end{aligned}$$

For each $(p, X_1, \dots, X_k) \in \mathcal{M}_k$, we define

$$\begin{aligned} \mathcal{E}(p, X_1, \dots, X_k) &= \{X \in M_p : \omega(p)(X_1, \dots, X_k, X) = 0 \text{ for all } \omega \in \mathcal{I}_{k+1}\} \\ &= \mathcal{E}(k\text{-dimensional integral element spanned by } X_1, \dots, X_k). \end{aligned}$$

We now define **regular** integral elements inductively as follows. The point p is a **regular** 0-dimensional integral element if $\dim \mathcal{E}_1(p') = \dim \mathcal{E}_1(p)$ for all p' in a neighborhood of p . A k -dimensional integral element W is **regular** if

- (a) W contains a $(k - 1)$ -dimensional regular integral element,
- (b) $\dim \mathcal{E}_{k+1}(W') = \dim \mathcal{E}_{k+1}(W)$ for all k -dimensional integral elements W' in a neighborhood of W .

In order to talk about a neighborhood of W , we have to specify the topology involved. The k -dimensional integral elements are topologized as a subset of the set of all k -dimensional subspaces of all M_q ; locally this looks like $\mathbb{R}^n \times (k\text{-dimensional subspaces of } \mathbb{R}^n)$, and we use the obvious topology on k -dimensional subspaces of \mathbb{R}^n (described in detail in Chapter 13, section 2).

Equivalently, W is regular if it has some basis X_1, \dots, X_k such that for each $h \leq k$ we have $\dim \mathcal{E}_{h+1}(p', X'_1, \dots, X'_h) = \dim \mathcal{E}_{h+1}(p, X_1, \dots, X_h)$ for all $(p', X'_1, \dots, X'_h) \in \mathcal{M}_h$ in a neighborhood of (p, X_1, \dots, X_h) . Notice that the definition does not preclude the possibility that the regular k -dimensional integral element W contains a $(k-1)$ -dimensional integral element which is not regular. That is why our second criterion for regularity merely requires the existence of *some* basis (X_1, \dots, X_k) with the requisite property—there may also be bases which do not have this property. A basis (X_1, \dots, X_k) which does have the required property will be called **good**.

For a k -dimensional integral element W , consider the codimension

$$c_{k+1}(W) = n - \dim \mathcal{E}_{k+1}(W);$$

similarly, for $(p, X_1, \dots, X_k) \in \mathcal{M}_k$, set

$$c_{k+1}(p, X_1, \dots, X_k) = n - \dim \mathcal{E}_{k+1}(p, X_1, \dots, X_k).$$

Clearly $c_{k+1}(W)$ is the maximum number of $(k+1)$ -forms $\omega^{(1)}, \omega^{(2)}, \dots \in \mathcal{L}_{k+1}$ such that the $c_{k+1}(W)$ linear functions

$$Y \mapsto \omega^{(\alpha)}(p)(X_1, \dots, X_k, Y) \quad Y \in M_p \quad ((X_1, \dots, X_k) \text{ a basis of } W)$$

are linearly independent. It follows that the function $W \mapsto c_{k+1}(W)$ is lower semi-continuous on the set of all k -dimensional integral elements [that is, the value of this function may be greater than $c_{k+1}(W)$ arbitrarily close to W , but it cannot be less than $c_{k+1}(W)$ arbitrarily close to W]. Consequently, the function $W \mapsto \dim \mathcal{E}_{k+1}(W)$ is *upper* semi-continuous. It follows easily that condition (b) holds on an open dense subset of the set of all k -dimensional integral elements. It certainly holds if $\dim \mathcal{E}_{k+1}(W)$ has the minimum possible value. [In particular, condition (b) holds if $\dim \mathcal{E}_{k+1}(W) = 0$, in which case there is no $(k+1)$ -dimensional integral element containing W .] It is easy to see that if M is a connected analytic manifold, and we consider only *analytic* forms, then condition (b) is equivalent to $\dim \mathcal{E}_{k+1}(W)$ having the minimum possible value.

The appropriateness of the regularity condition is attested to by the following

14. LEMMA. Let \mathcal{L} be a homogeneous ideal with $\mathcal{L}_0 = 0$. If $X_1, \dots, X_k \in M_p$ is a good basis for a regular k -dimensional integral element of \mathcal{L} , and $X_{k+1} \in \mathcal{E}_{k+1}(p, X_1, \dots, X_k)$ is linearly independent of X_1, \dots, X_k , then near (p, X_1, \dots, X_{k+1}) , the set \mathcal{M}_{k+1} is a submanifold of $M \times TM \times \dots \times TM$, of dimension

$$n(k+2) - c_1(p) - c_2(p, X_1) - \dots - c_{k+1}(p, X_1, \dots, X_k).$$

PROOF. We can assume that $M = \mathbb{R}^n$. Recall that for $Y \in \mathbb{R}^n$, we let $Y_q = (q, Y)$ be the corresponding tangent vector $\in \mathbb{R}^n_q$. Choose A_1, \dots, A_k with $X_i = (A_i)_p$. Set

$$\tilde{\mathcal{M}}_{k+1} = \{(q, Y_1, \dots, Y_{k+1}) \in \mathbb{R}^{n(k+2)} : (q, (Y_1)_q, \dots, (Y_{k+1})_q) \in \mathcal{M}_{k+1}\}.$$

Then \mathcal{M}_{k+1} is the image of $\tilde{\mathcal{M}}_{k+1}$ under an imbedding $\mathbb{R}^{n(k+2)} \rightarrow \mathbb{R}^n \times T\mathbb{R}^n \times \dots \times T\mathbb{R}^n$, so it suffices to prove that $\tilde{\mathcal{M}}_{k+1}$ is a manifold. We will use induction on k , the case $k = 0$ being easy. So suppose that $\tilde{\mathcal{M}}_h \subset \mathbb{R}^{n(h+1)}$ is known to be a submanifold, of dimension

$$(1) \quad \dim \tilde{\mathcal{M}}_h = n(h+1) - c_1(p) - \dots - c_h(p, X_1, \dots, X_{h-1}).$$

For convenience, set

$$c_{h+1} = c_{h+1}(p, X_1, \dots, X_h).$$

Choose c_{h+1} $(h+1)$ -forms $\omega^{(1)}, \omega^{(2)}, \dots \in \mathfrak{L}_{h+1}$ such that the c_{h+1} linear functions

$$(*) \quad Y \mapsto \omega^{(\alpha)}(p)(X_1, \dots, X_h, Y_p)$$

are linearly independent. We adopt the convention that if $q, Y_1, \dots, Y_{h+1} \in \mathbb{R}^n$, then

$$\omega^{(\alpha)}(q, Y_1, \dots, Y_{h+1}) \quad \text{denotes} \quad \omega^{(\alpha)}(q)((Y_1)_q, \dots, (Y_{h+1})_q).$$

Thus we can consider $\omega^{(\alpha)}$ as a function on $\mathbb{R}^{n(h+2)}$. Since X_1, \dots, X_h is a good basis, we know that for $(q, Y_1, \dots, Y_h) \in \tilde{\mathcal{M}}_h$ close to (p, A_1, \dots, A_h) , the linear functions

$$Y \mapsto \omega^{(\alpha)}(q, Y_1, \dots, Y_h, Y)$$

already span the set of linear functions

$$Y \mapsto \omega(q, Y_1, \dots, Y_h, Y) \quad \text{for all } \omega \in \mathfrak{L}_{h+1}.$$

This means that near (p, A_1, \dots, A_h) , the set $\tilde{\mathcal{M}}_{h+1}$ is precisely the set of $(q, Y_1, \dots, Y_h, Y_{h+1})$ such that

$$\begin{cases} (q, Y_1, Y_h) \in \tilde{\mathcal{M}}_h \\ \omega^{(\alpha)}(q, Y_1, \dots, Y_h, Y_{h+1}) = 0 \end{cases} \quad \alpha = 1, \dots, c_{h+1}.$$

Thus, if we define

$$F: \tilde{\mathcal{M}}_h \times \mathbb{R}^n \rightarrow \mathbb{R}^{c_{h+1}}$$

by

$$\begin{aligned} F(q, Y_1, \dots, Y_h, Y_{h+1}) \\ = (\omega^{(1)}(q, Y_1, \dots, Y_h, Y_{h+1}), \omega^{(2)}(q, Y_1, \dots, Y_h, Y_{h+1}), \dots), \end{aligned}$$

then $\tilde{\mathcal{M}}_{h+1}$ is just $F^{-1}(0)$ near $(p, A_1, \dots, A_h, A_{h+1})$. Let Z_1, \dots, Z_n denote the

last n basis vectors of $\mathbb{R}^{n(h+2)}$. Then the linear independence of the functions (*) shows that the vectors

$$F_*((Z_i)_{(p, A_1, \dots, A_h, A_{h+1})}) \in (\mathbb{R}^{c_{h+1}})_0$$

are linearly independent. Thus F_* has rank c_{h+1} at $(p, A_1, \dots, A_h, A_{h+1})$. So in a neighborhood of $(p, A_1, \dots, A_h, A_{h+1})$ the set

$$\tilde{\mathcal{M}}_{h+1} = F^{-1}(0) \subset \tilde{\mathcal{M}}_h \times \mathbb{R}^n$$

is a manifold, of dimension

$$\begin{aligned} \dim \tilde{\mathcal{M}}_{h+1} &= \dim(\tilde{\mathcal{M}}_h \times \mathbb{R}^n) - c_{h+1} \\ &= n(h+2) - c_1(p) - \dots - c_h(p, X_1, \dots, X_{h-1}) - c_{h+1}, \quad \text{by (I). } \spadesuit \end{aligned}$$

Our goal is to show that if our ideal \mathcal{I} is a differential system ($d\mathcal{I} \subset \mathcal{I}$), then, at least in the analytic case, a k -dimensional integral element at p which contains a $(k-1)$ -dimensional regular integral element (but which need not be regular itself), is the tangent space at p of some k -dimensional integral submanifold of \mathcal{I} . We will derive this result as a corollary of a more precise one, which tells when a k -dimensional integral submanifold of \mathcal{I} can be extended to a $(k+1)$ -dimensional integral submanifold.

Suppose $W \subset M_p$ is a k -dimensional regular integral element of \mathcal{I} which is the tangent space at p of some k -dimensional integral submanifold N of \mathcal{I} .

Suppose that $\dim \mathcal{E}_{k+1}(W) > k$, so that there is a vector $X \in \mathcal{E}_{k+1}(W)$ which is not in W ; then $W \oplus \mathbb{R} \cdot X$ is a $(k+1)$ -dimensional integral element. We will show that there is a $(k+1)$ -dimensional integral manifold $N' \supset N$ whose tangent space at p is $W \oplus \mathbb{R} \cdot X$. We can also say precisely how many such integral manifolds N' there are. To do this, we choose a submanifold P of M of dimension

$$\dim P = k + 1 + c_{k+1}(W),$$

such that

- (a) $P \supset N$
- (b) $P_p \cap \mathcal{E}_{k+1}(W) = W \oplus \mathbb{R} \cdot X$.

We will show that near p there is an (essentially unique) $(k+1)$ -dimensional integral submanifold N' of \mathcal{I} with $N \subset N' \subset P$ and $N'_p = W \oplus \mathbb{R} \cdot X$.

All such submanifolds P can be described locally as follows. Choose $Z \subset M_p$ with $\mathcal{E}_{k+1}(W) \oplus Z = M_p$, so that

$$\dim Z = n - \dim \mathcal{E}_{k+1}(W) = c_{k+1}(W).$$

Then $W \oplus \mathbb{R} \cdot X \oplus Z$ has dimension

$$\dim(W \oplus \mathbb{R} \cdot X \oplus Z) = k + 1 + c_{k+1}(W).$$

Also choose $U \subset M_p$ with $W \oplus \mathbb{R} \cdot X \oplus U = \mathcal{E}_{k+1}(W)$, so that

$$\dim U = \dim \mathcal{E}_{k+1}(W) - k - 1.$$

Then P can be written as the graph of a function from $W \oplus \mathbb{R} \cdot X \oplus Z$ to U . In classical terminology, the submanifolds P , and hence the desired integral manifolds N' , “depend on $\dim \mathcal{E}_{k+1}(W) - k - 1$ arbitrary functions of $k + 1 + c_{k+1}(W)$ variables”.

To prove that N' exists, we can assume without loss of generality that $M = \mathbb{R}^n$, with $p = 0 \in \mathbb{R}^n$, and that

$$\begin{aligned} (e_1)_0, \dots, (e_k)_0 &\text{ is a good basis for } W \\ X &\text{ is } (e_{k+1})_0 \\ \mathcal{E}_{k+1}(W) &\text{ is spanned by } (e_1)_0, \dots, (e_k)_0, (e_{k+1})_0, \dots, (e_l)_0 \\ Z &\text{ is spanned by } (e_{l+1})_0, \dots, (e_n)_0 \\ U &\text{ is spanned by } (e_{k+2})_0, \dots, (e_l)_0. \end{aligned}$$

By Theorem I.2-10(2), we can assume, by composing \mathbb{R}^n with a diffeomorphism, that

$$(1) \quad P = \{(x^1, \dots, x^{k+1}, 0, \dots, 0, x^{l+1}, \dots, x^n)\}.$$

Let N be

$$N = \{(x^1, \dots, x^k, f_{k+1}(x^1, \dots, x^k), \dots, f_n(x^1, \dots, x^k))\},$$

for certain functions f_{k+1}, \dots, f_n with

$$(2) \quad D_i f_t = 0 \quad i = 1, \dots, k; \quad t = k + 1, \dots, n.$$

In order to have $P \supset N$ we must have

$$\begin{aligned} f_{k+1}(x^1, \dots, x^k) &= x^{k+1} \\ f_{k+2}(x^1, \dots, x^k) &= \dots = f_l(x^1, \dots, x^k) = 0 \\ f_v(x^1, \dots, x^k) &= x^v \quad v = l + 1, \dots, n. \end{aligned}$$

Now the map

$$(x^1, \dots, x^n) \mapsto (x^1, \dots, x^l, x^{l+1} - f_{l+1}(x^1, \dots, x^k), \dots, x^n - f_n(x^1, \dots, x^k))$$

has Jacobian matrix equal to the identity at 0, by (2); so by another application of Theorem I.2-10(2) we can assume that

$$(3) \quad N = \{(x^1, \dots, x^k, 0, \dots, 0)\}.$$

The required N' must be of the form

$$(4) \quad N' = \{(x^1, \dots, x^{k+1}, 0, \dots, 0, g_{l+1}(x^1, \dots, x^{k+1}), \dots, g_n(x^1, \dots, x^{k+1}))\},$$

where the functions g_v satisfy

$$(5) \quad g_v(x^1, \dots, x^k, 0) = 0 \quad v = l+1, \dots, n.$$

If

$$\omega = \sum_{i_1 < \dots < i_{k+1}} \omega_{i_1 \dots i_{k+1}} dx^{i_1} \wedge \dots \wedge dx^{i_{k+1}}$$

is any $(k+1)$ -form, then ω restricted to N' is zero if and only if the coefficient of $dx^1 \wedge \dots \wedge dx^{k+1}$ is zero when we replace

$$\begin{aligned} \omega_{i_1 \dots i_{k+1}} & \text{ by} \\ (x^1, \dots, x^{k+1}) & \mapsto \omega_{i_1 \dots i_{k+1}}(x^1, \dots, x^{k+1}, 0, \dots, 0, g_{l+1}(x^1, \dots, x^{k+1}), \\ & \dots, g_n(x^1, \dots, x^{k+1})) \end{aligned}$$

$$dx^j \text{ by } 0 \quad j = k+2, \dots, l$$

$$dx^v \text{ by } \sum_{i=1}^{k+1} \frac{\partial g_v}{\partial x^i} dx^i \quad v = l+1, \dots, n.$$

Thus ω restricted to N' is zero if and only if

$$\begin{aligned} & \sum_{\mu=l+1}^n \omega_{12 \dots p \mu}(x^1, \dots, x^{k+1}, 0, \dots, 0, g_{l+1}(x^1, \dots, x^{k+1}), \\ & \dots, g_n(x^1, \dots, x^{k+1})) \frac{\partial g_\mu}{\partial x^{k+1}} \\ & = \text{certain terms involving the } \partial g_\rho / \partial x^h, \quad h \leq k. \end{aligned}$$

We can write this as

$$\begin{aligned} (6) \quad & \sum_{\mu=l+1}^n C_\mu(x^1, \dots, x^{k+1}, g_{l+1}, \dots, g_n) \cdot \frac{\partial g_\mu}{\partial x^{k+1}} \\ & = D \left(x^1, \dots, x^{k+1}, \dots, g_\rho, \dots, \frac{\partial g_\rho}{\partial x^h}, \dots \right) \\ & \quad [\text{all } g_\rho \text{ and } \partial g_\rho / \partial x^h \text{ evaluated at } (x^1, \dots, x^{k+1})], \end{aligned}$$

where

$$(7) \quad C_\mu(x^1, \dots, x^{k+1}, g_{l+1}, \dots, g_n) \\ = \omega_{12 \dots p\mu}(x^1, \dots, x^{k+1}, 0, \dots, 0, g_{l+1}, \dots, g_n).$$

Choose $n - l$ ($k + 1$)-forms

$$\omega^{l+1}, \dots, \omega^n \in \mathfrak{L}_{k+1}$$

so that, with the conventions of the proof of Lemma 14, the $n - l$ linear functions

$$Y \mapsto \omega^{(v)}(0, e_1, \dots, e_k, Y)$$

are linearly independent. This means that

$$0 \neq \det(\omega^{(v)}(0, e_1, \dots, e_k, e_\mu)) \quad l + 1 \leq \mu, v \leq n.$$

So if we write $\omega^{(v)}$ as

$$\omega^{(v)} = \sum_{i_1 < \dots < i_{k+1}} \omega_{i_1 \dots i_{k+1}}^{(v)} dx^{i_1} \wedge \dots \wedge dx^{i_{k+1}},$$

then

$$(8) \quad 0 \neq \det(\omega_{12 \dots k\mu}^{(v)}(0)) \quad l + 1 \leq \mu, v \leq n.$$

Consider the equations (6) for each $\omega^{(v)}$:

$$(9) \quad \sum_{\mu=l+1}^n C_\mu^{(v)}(x^1, \dots, x^{k+1}, g_{l+1}, \dots, g_n) \frac{\partial g_\mu}{\partial x^{k+1}} \\ = D \left(x^1, \dots, x^{k+1}, \dots, g_\rho, \dots, \frac{\partial g_\rho}{\partial x^h}, \dots \right).$$

Equation (7), together with (8), shows that

$$0 \neq \det(C_\mu^{(v)}(0)) \quad l + 1 \leq \mu, v \leq n.$$

So equations (9) can be written, near 0, as

$$(10) \quad \frac{\partial g_v}{\partial x^{k+1}} = E_v \left(x^1, \dots, x^{k+1}, \dots, g_\rho, \dots, \frac{\partial g_\rho}{\partial x^h}, \dots \right).$$

Now we have arrived at a familiar looking problem.

15. **THEOREM (THE CARTAN-KÄHLER THEOREM).** Let M be an analytic manifold, and let \mathcal{I} be a differential system (of analytic forms) with $\mathcal{I}_0 = 0$. Let $W \subset M_p$ be a regular k -dimensional integral element, and let N be a k -dimensional integral submanifold of \mathcal{I} with $N_p = W$. Let $X \in \mathcal{E}_{k+1}(W)$ be a vector not in W , and let P be an analytic submanifold of M of dimension $k + 1 + c_{k+1}(W)$ such that $P \supset N$ and $P_p \cap \mathcal{E}_{k+1}(W) = W \oplus \mathbb{R} \cdot X$. Then there is a unique analytic $(k + 1)$ -dimensional integral submanifold N' of \mathcal{I} with $N \subset N' \subset P$ and $N'_p = W \oplus \mathbb{R} \cdot X$.

PROOF. The previous considerations show that the existence of N' is equivalent to the existence of functions g_ν satisfying

$$g_\nu(x^1, \dots, x^k, 0) = 0 \quad \nu = l + 1, \dots, n$$

and also equations (6) for all $\omega \in \mathcal{I}_{k+1}$. In particular, the functions g_ν must satisfy (10), with the above initial conditions. The Cauchy-Kowalewski theorem (together with the considerations at the end of section 3) shows that there are unique analytic functions g_ν with this property. This already proves uniqueness, and proves the existence of N' , with inclusion map $i: N' \rightarrow \mathbb{R}^n$, satisfying

$$i^* \omega^{l+1} = \dots = i^* \omega^n = 0.$$

To complete the proof of existence we must show that $i^* \omega = 0$ for all $\omega \in \mathcal{I}_{k+1}$. Here is where the regularity of W is required.

We will continue to use the convention in the proof of Lemma 14. For each $h \leq k$, choose $(h + 1)$ -forms $\omega_{h+1}^{(\alpha)}$ such that the linear functions

$$Y \mapsto \omega_{h+1}^{(\alpha)}(0, e_1, \dots, e_h, Y) \quad \alpha = 1, \dots, c_{h+1} = c_{h+1}(0, e_1, \dots, e_h)$$

are linearly independent. Thus the forms $\omega_{k+1}^{(\alpha)}$ are the forms $\omega^{l+1}, \dots, \omega^n$ introduced previously. Consider the $(k + 1)$ -forms

$$(I) \quad \left\{ \begin{array}{ll} \omega_1^{(\alpha)} \wedge dx^2 \wedge dx^3 \wedge \dots \wedge dx^{k+1} & \alpha = 1, \dots, c_1 \\ \omega_2^{(\alpha)} \wedge dx^3 \wedge \dots \wedge dx^{k+1} & \alpha = 1, \dots, c_2 \\ \vdots & \\ \omega_{k+1}^{(\alpha)} & \alpha = 1, \dots, c_{k+1}. \end{array} \right.$$

We use all of these forms to construct a map $G: \mathbb{R}^{n(k+2)} \rightarrow \mathbb{R}^{c_1 + \dots + c_{k+1}}$, defined by

$$G(q, Y_1, \dots, Y_{k+1}) = \left((\omega_1^{(1)} \wedge dx^2 \wedge \dots \wedge dx^{k+1})(q, Y_1, \dots, Y_{k+1}), \right. \\ \left. \dots, \omega_{k+1}^{(c_{k+1})}(q, Y_1, \dots, Y_{k+1}) \right).$$

Since

$$\omega_i^{(\alpha)} \in \mathcal{I}_i \implies (\omega_i^{(\alpha)} \wedge dx^{i+1} \wedge \dots \wedge dx^{k+1})(0, e_1, \dots, e_i, \dots, Y_h, \dots, e_{k+1}) = 0,$$

the Jacobian matrix of G has the form

$$\begin{array}{c} c_1 \{ \\ c_2 \{ \\ \vdots \\ c_{k+1} \{ \end{array} \begin{pmatrix} q & Y_1 & Y_2 & Y_3 & \dots & Y_{k+1} \\ \boxed{A_1} & 0 & 0 & \dots & 0 \\ & \boxed{A_2} & 0 & \dots & 0 \\ & & \boxed{A_3} & & \vdots \\ & & & \ddots & 0 \\ & & & & \boxed{A_{k+1}} \end{pmatrix} \quad \text{at } (0, e_1, \dots, e_{k+1}).$$

By our choice of the $\omega_{h+1}^{(\alpha)}$, the block A_{h+1} has rank c_{h+1} . So the whole matrix has maximal rank $c_1 + \dots + c_{k+1}$. Thus $G^{-1}(0)$ is an (analytic) submanifold of $\mathbb{R}^{c_1 + \dots + c_{k+1}}$ near $(0, e_1, \dots, e_{k+1})$, of dimension $n(k+2) - c_1 - \dots - c_{k+1}$. But the forms (I) are all in the ideal \mathcal{I} , so $G^{-1}(0)$ contains the manifold $\tilde{\mathcal{M}}_{k+1}$ in the proof of Lemma 14. It also has the same dimension as this manifold, so it *equals* this manifold near $(0, e_1, \dots, e_{k+1})$. We will write the forms in (I) as

$$(II) \quad \begin{cases} \eta^{(\beta)} \wedge dx^{k+1} & \beta = 1, \dots, d = c_1 + \dots + c_k \\ \omega_{k+1}^{(\alpha)} & \alpha = 1, \dots, c_{k+1}, \end{cases}$$

where the forms $\eta^{(\beta)}$ are all in \mathcal{I}_k .

Now consider an arbitrary $(k+1)$ -form $\omega \in \mathcal{I}_{k+1}$. Since W is a regular integral element, we know that we can write

$$\omega(q, Y_1, \dots, Y_k, Y) = \sum_{\alpha=1}^{c_{k+1}} B_{\alpha}(q, Y_1, \dots, Y_k) \cdot \omega_{k+1}^{(\alpha)}(q, Y_1, \dots, Y_k, Y)$$

for all $(q, Y_1, \dots, Y_k) \in \tilde{\mathcal{M}}_k$ close to $(0, e_1, \dots, e_k)$. The functions B_{α} can be solved for explicitly by Cramer's rule, so they are actually analytic functions in a whole neighborhood of $(0, e_1, \dots, e_k)$ in $\mathbb{R}^{n(k+1)}$, even though the equation need hold only for $(q, Y_1, \dots, Y_k) \in \tilde{\mathcal{M}}_k$. We may express this situation as

follows:

$$\left\{ \begin{array}{l} \text{the function} \\ \text{(a)} \quad \omega - \sum_{\alpha=1}^{c_{k+1}} B_{\alpha} \omega^{(\alpha)} \\ \text{on } \mathbb{R}^{n(k+2)} \text{ vanishes on the submanifold } \tilde{\mathcal{M}}_k \times \mathbb{R}^n, \text{ and hence on the} \\ \text{(analytic) submanifold } \tilde{\mathcal{M}}_{k+1}, \text{ defined by the equations} \\ \text{(b)} \quad \eta^{(\beta)} \wedge dx^{k+1} = 0, \quad \omega_{k+1}^{(\alpha)} = 0. \end{array} \right.$$

It follows easily (Problem 1) that locally the function (a) is a sum of analytic functions times the functions in (b). Consequently, we can write

$$\begin{aligned} \omega(q, Y_1, \dots, Y_{k+1}) &= \sum_{\alpha=1}^{c_{k+1}} C_{\alpha}(q, Y_1, \dots, Y_{k+1}) \cdot \omega^{(\alpha)}(q, Y_1, \dots, Y_{k+1}) \\ &\quad + \sum_{\beta=1}^d D_{\beta}(q, Y_1, \dots, Y_{k+1}) \cdot (\eta^{(\beta)} \wedge dx^{k+1})(q, Y_1, \dots, Y_{k+1}), \end{aligned}$$

for analytic C_{α} and D_{β} . This implies that if $q \in N'$, and Y_1, \dots, Y_{k+1} are tangent to N' , then

$$\begin{aligned} (i^* \omega)(q, Y_1, \dots, Y_{k+1}) &= 0 + \sum_{\beta=1}^d D_{\beta}(q, Y_1, \dots, Y_{k+1}) i^*(\eta^{(\beta)} \wedge dx^{k+1})(q, Y_1, \dots, Y_{k+1}). \end{aligned}$$

So it suffices to show that

$$i^*(\eta^{(\beta)} \wedge dx^{k+1}) = 0 \quad \beta = 1, \dots, d.$$

From the form of N' (equation (4) on page 119) it is clear that x^1, \dots, x^{k+1} is a coordinate system on N' . So we write each $i^* \eta^{(\beta)}$ as

$$i^* \eta^{(\beta)} = \sum_{j=1}^{k+1} (-1)^{j+1} h_j^{(\beta)} dx^1 \wedge \dots \wedge \widehat{dx^j} \wedge \dots \wedge dx^{k+1}.$$

Now the above analysis for the $(k+1)$ -form $\omega \in \mathfrak{L}_{k+1}$ can be applied, in particular, for $\omega = \eta^{(\beta)} \wedge dx^j$. Thus each $i^*(\eta^{(\beta)} \wedge dx^j)$ is a linear combination, with analytic coefficients, of the forms $i^*(\eta^{(\beta)} \wedge dx^{k+1})$. Since

$$\begin{aligned} i^*(dx^j \wedge \eta^{(\beta)}) &= dx^j \wedge i^*\eta^{(\beta)} = h_j^{(\beta)} dx^1 \wedge \cdots \wedge dx^{k+1} & j \leq k \\ i^*(dx^{k+1} \wedge \eta^{(\beta)}) &= h_{k+1}^{(\beta)} dx^1 \wedge \cdots \wedge dx^{k+1} \\ &= H^{(\beta)} dx^1 \wedge \cdots \wedge dx^{k+1}, \quad \text{say,} \end{aligned}$$

this shows that we can write $h_j^{(\beta)}$ for $j \leq k$ as an analytic linear combination of the $H^{(\beta)}$,

$$h_j^{(\beta)} = \sum_{\gamma=1}^d E_{j\beta\gamma} H^{(\gamma)}.$$

Since $d\mathfrak{L} \subset \mathfrak{L}$, we can also write each $i^*d\eta^{(\beta)}$ as a linear combination of the $i^*(\eta^{(\beta)} \wedge dx^{k+1})$,

$$i^*d\eta^{(\beta)} = \sum_{\gamma=1}^d F_{\beta\gamma} H^{(\gamma)} dx^1 \wedge \cdots \wedge dx^{k+1}.$$

But

$$\begin{aligned} i^*d\eta^{(\beta)} &= di^*\eta^{(\beta)} \\ &= d\left(\sum_{j=1}^{k+1} (-1)^{j+1} h_j^{(\beta)} dx^1 \wedge \cdots \wedge \widehat{dx^j} \wedge \cdots \wedge dx^{k+1}\right) \\ &= \left[\frac{\partial h_1^{(\beta)}}{\partial x^1} + \cdots + \frac{\partial h_{k+1}^{(\beta)}}{\partial x^{k+1}}\right] dx^1 \wedge \cdots \wedge dx^{k+1} \\ &= \left[\frac{\partial(\sum_{\gamma} E_{1\beta\gamma} H^{(\gamma)})}{\partial x^1} + \cdots + \frac{\partial(\sum_{\gamma} E_{k\beta\gamma} H^{(\gamma)})}{\partial x^k} + \frac{\partial H^{(\beta)}}{\partial x^{k+1}}\right] dx^1 \wedge \cdots \wedge dx^{k+1}. \end{aligned}$$

Comparing with the original expression for $i^*d\eta^{(\beta)}$, we see that we have a system of equations

$$(*) \quad \frac{\partial H^{(\beta)}}{\partial x^{k+1}} = \sum_{\gamma=1}^d F_{\beta\gamma} H^{(\gamma)} + \sum_{j=1}^k G_{j\beta\gamma} \frac{\partial H^{(\gamma)}}{\partial x^j}, \quad \beta = 1, \dots, d,$$

with everything in sight being analytic. Finally, we have to use the fact that the original manifold N (equation (3) on page 119) is an integral submanifold of \mathcal{L} . This implies that all forms $\eta^{(\beta)}$ vanish on N , which means that

$$(*) \quad H^{(\beta)}(x^1, \dots, x^k, 0) = 0, \quad \beta = 1, \dots, d.$$

The uniqueness part of the Cauchy-Kowalewski theorem shows that the only solutions $H^{(\beta)}$ of $(*)$ with the initial conditions $(*_0)$ is $H^{(\beta)} = 0$. Thus all $h_j^{(\beta)} = 0$, so all $i^*\eta^{(\beta)} = 0$. ♦

As an immediate consequence we obtain

16. COROLLARY. Let M be an analytic manifold, and let \mathcal{L} be a differential system (of analytic forms) with $\mathcal{L}_0 = 0$. Let $W \subset M_p$ be a k -dimensional integral element which contains a regular $(k - 1)$ -dimensional integral element. Then there is a k -dimensional analytic integral submanifold N of \mathcal{L} with $N_p = W$.

PROOF. Choose a good basis X_1, \dots, X_k of W , and consider the subspaces $W_1 \subset W_2 \subset \dots \subset W_k$ with W_i the subspace spanned by X_1, \dots, X_i . The desired result then follows by induction from Theorem 15, starting with p as a 0-dimensional integral submanifold. ♦

The reader may easily check that if \mathcal{L} is an ideal generated by linearly independent 1-forms $\omega_1, \dots, \omega_l$, then for every k -dimensional integral element W we have $c_{k+1}(W) = n - l$. Consequently, every integral element is regular. Thus the Frobenius theorem follows, in the analytic case, from the Cartan-Kähler theorem.

As a final remark, we point out that it is not hard to take care of the case $\mathcal{L}_0 \neq 0$. One merely has to assume that $\{q \in M : f(q) = 0 \text{ for all } f \in \mathcal{L}_0\}$ is a submanifold $M' \subset M$ near p , and then apply the previous considerations to $\mathcal{L}|_{M'}$.

ADDENDUM 2

AN ELEMENTARY MAXIMUM PRINCIPLE

It is well-known that if u is harmonic ($\partial^2 u / \partial x^2 + \partial^2 u / \partial y^2 = 0$), then u cannot have a relative maximum at an interior point of an open set. A more general principle holds, and its proof, although tricky, is elementary.

On an open set $U \subset \mathbb{R}^n$, consider the second order differential operator L defined by

$$(*) \quad Lu = \sum_{i,j=1}^n a_{ij} \frac{\partial^2 u}{\partial x_i \partial x_j} + \sum_{i=1}^n b_i \frac{\partial u}{\partial x_i} + cu,$$

for certain functions a_{ij}, b_i, c on U . We assume that $a_{ij} = a_{ji}$, and that the matrix $A = (a_{ij})$ is everywhere definite. [Thus the equation $Lu = 0$ is the most general second order linear elliptic equation.] To be more specific, we will assume that $A = (a_{ij})$ is *positive* definite. Thus $\sum_{i,j} a_{ij} \xi_i \xi_j > 0$ for $0 \neq \xi \in \mathbb{R}^n$; equivalently, if t denotes the transpose, the 1×1 matrix

$$\xi \cdot A \cdot \xi^t > 0 \quad \text{for } 0 \neq \xi \in \mathbb{R}^n.$$

An elementary observation about definite matrices will be needed. Suppose that B is also positive definite, so that

$$\xi \cdot B \cdot \xi^t > 0 \quad \text{for } 0 \neq \xi \in \mathbb{R}^n.$$

For any non-singular matrix P we then have

$$\xi \cdot PBP^t \cdot \xi^t = (\xi P)B(\xi P)^t > 0 \quad \text{for } 0 \neq \xi \in \mathbb{R}^n,$$

so $PBP^t = C = (c_{ij})$ is also positive definite. Now the symmetric matrix A can be diagonalized—there is an orthogonal matrix P such that

$$PAP^{-1} = PAP^t = \begin{pmatrix} \lambda_1 & & 0 \\ & \ddots & \\ 0 & & \lambda_n \end{pmatrix} \quad \lambda_i > 0.$$

Then

$$\begin{aligned} \text{trace } AB &= \text{trace } PABP^t = \text{trace}(PAP^t)(PBP^t) \\ &= \text{trace} \begin{pmatrix} \lambda_1 & & 0 \\ & \ddots & \\ 0 & & \lambda_n \end{pmatrix} C \\ &= \text{trace}(\lambda_i c_{ij}) \\ &= \sum_i \lambda_i c_{ii} > 0. \end{aligned}$$

Similarly, we have $\text{trace } AB \geq 0$ if B is positive semi-definite, and $\text{trace } AB \leq 0$ if B is negative semi-definite.

Now consider the operator $(*)$, where we assume that

$$(i) \quad c \leq 0 \quad \text{in } U.$$

Suppose that $u: U \rightarrow \mathbb{R}$ is a twice differentiable function with a relative maximum at some point $p \in U$. Assume, moreover, that

$$(ii) \quad u(p) \geq 0.$$

From (i) and (ii) we have

$$(iii) \quad \sum_{i,j=1}^n a_{ij} \frac{\partial^2 u}{\partial x_i \partial x_j}(p) = (Lu)(p) - c(p)u(p) \geq Lu(p).$$

On the other hand, since u has a relative maximum at p , the matrix

$$B = \left(\frac{\partial^2 u}{\partial x_i \partial x_j}(p) \right)$$

is negative semi-definite. Hence we have

$$(iv) \quad 0 \geq \text{trace } A(p) \cdot B = \sum_{i,j=1}^n a_{ij} \frac{\partial^2 u}{\partial x_i \partial x_j}(p).$$

Since (iii) and (iv) imply that $Lu(p) \leq 0$, we find

- (A) If the operator $(*)$ has (a_{ij}) positive definite on U and $c \leq 0$ on U , and the twice differentiable function u satisfies $Lu > 0$ on U , then u cannot have a non-negative relative maximum on U .

The significant fact is that we can replace the condition $Lu > 0$ by $Lu \geq 0$, provided that we consider actual maxima rather than relative maxima.

17. THEOREM (E. HOPF). Consider a second order differential operator

$$Lu = \sum_{i,j=1}^n a_{ij} \frac{\partial^2 u}{\partial x_i \partial x_j} + \sum_{i=1}^n b_i \frac{\partial u}{\partial x_i} + cu \quad c \leq 0$$

on a connected open set $U \subset \mathbb{R}^n$. Assume that the functions b_i and c are locally bounded, and that in a neighborhood of any point of U there are constants $\varepsilon, M > 0$ such that the matrix (a_{ij}) satisfies

$$\varepsilon \cdot \sum_{i=1}^n \xi_i^2 \leq \sum_{i,j=1}^n a_{ij} \xi_i \xi_j \leq M \cdot \sum_{i=1}^n \xi_i^2 \quad \xi \in \mathbb{R}^n.$$

Suppose that u is a twice differentiable function on U satisfying

$$Lu \geq 0.$$

Then u cannot have a non-negative maximum on U , unless u is a constant.

PROOF. Suppose u has a maximum at $p \in U$, with $u(p) \geq 0$. If u is not constant, then there is clearly a point $q \in U$ and an open ball B centered at q with $\bar{B} \subset U$ such that $u(q) < u(p)$, but $u(p^*) = u(p)$ for some $p^* \in$ boundary B . Moreover, by choosing the smallest ball B with this property, we

can assume that $u < u(p)$ in B . Let r be a point on the open segment $\overline{qp^*}$, set

$$\rho = d(r, p^*) \quad \text{and choose} \quad 0 < \rho' < \rho.$$

Let B' be the open ball of radius ρ' around p^* ; assume ρ' chosen sufficiently small so that $\bar{B'} \subset U$.

Now consider the function

$$v(x) = e^{-kd(r,x)^2} - e^{-k\rho^2}$$

$$Lv(x) = e^{-kd(r,x)^2} \left[4k^2 \sum_{i,j} a_{ij} (x_i - r_i)(x_j - r_j) - 2k \sum_i b_i (x_i - r_i) \right] + c \left[e^{-k\rho^2} - e^{-kd(r,x)^2} \right].$$
$$(1) \quad L(u + \lambda v) = Lu + \lambda Lv > 0 \quad \text{in } \overline{B'}.$$
$$(2) \quad v(p^*) = 0 \implies (u + \lambda v)(p^*) = u(p^*) = u(p).$$
$$\begin{aligned} x \in C &\implies d(x, r) > \rho \\ &\implies v(x) < 0 \\ x \in D &\implies x \in B \implies u(x) < u(p). \end{aligned}$$

$$(3) \quad u + \lambda v < u(p) \quad \text{on } S'.$$

The example

$$u = -(x^2 + y^2) - 4$$
$$Lu = \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} - u = x^2 + y^2 \geq 0$$

shows that the function u in Theorem 17 may well have a negative maximum on U . The example

$$u = -(x^2 + y^2) + 5$$

$$Lu = \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + u = 1 - (x^2 + y^2) \geq 0 \quad \text{for } x^2 + y^2 \leq 1$$

shows that the hypothesis $c \leq 0$ is essential. If we assume $c = 0$, then we get a stronger conclusion:

18. COROLLARY. Consider the operator L of Theorem 17, with $c = 0$. If u is a twice differentiable function on U with $Lu \geq 0$, then u cannot have a maximum on U unless u is a constant.

PROOF. Suppose u has a maximum at p . Let $v = u - u(p)$. Then v has a maximum of 0 at p . Moreover,

$$Lv = Lu \geq 0.$$

So Theorem 17 implies that v is a constant. ♦

As an application, consider a function $f: M \rightarrow \mathbb{R}$ on a Riemannian manifold M . Then we have the Laplacian Δf , defined in Addendum 1 to Chapter 7. In a coordinate system (x^1, \dots, x^n) on M , the formula for Δf (pg. IV.133) is precisely of the form considered in Corollary 18. So if $\Delta f \geq 0$, then Δf cannot have a maximum on M , unless f is a constant function. This gives another proof of Bochner's Lemma (Lemma 7-60).

In contrast to Corollary 18, where we assume $c = 0$, there is another result where c is arbitrary.

19. COROLLARY. Consider the operator L of Theorem 17, with arbitrary c . If u is a twice differentiable function on U with $Lu \geq 0$ and $u \leq 0$, then u cannot have the value 0 anywhere on U unless u is identically 0.

PROOF. Let

$$Pu = \sum_{i,j=1}^n a_{ij} \frac{\partial^2 u}{\partial x_i \partial x_j} + \sum_{i=1}^n b_i \frac{\partial u}{\partial x_i}.$$

Then we have

$$Pu + cu = Lu \geq 0.$$

Hence

$$Pu + \min(c, 0)u = [\min(c, 0) - c]u + Lu.$$

Now

$$\begin{aligned} \min(c, 0) &\leq 0 \\ \min(c, 0) - c &\leq 0 \implies [\min(c, 0) - c]u \geq 0 \quad \text{since } u \leq 0 \\ &\implies [\min(c, 0) - c]u + Lu \geq 0. \end{aligned}$$

Applying Theorem 17 to the operator $Pu + \min(c, 0)u$, we conclude that u cannot have a non-negative maximum unless it is a constant. ♦

There is also a version of Theorem 17 when u has its maximum at a boundary point of U .

20. THEOREM. Consider a second order differential operator L as in Theorem 17. Let u be a twice differentiable function on U satisfying $Lu \geq 0$ and such that at some point $p \in \text{boundary } U$ the function u has a maximum $u(p) \geq 0$ on $U \cup \{p\}$. Suppose moreover that there is some closed ball $\overline{B_\rho(r)} \subset U \cup \{p\}$ containing p on its boundary, and that the directional derivative of u at p in the

direction from p to r is ≥ 0 (all directional derivatives in directions tangent to the boundary of $B_\rho(r)$ are clearly equal to 0). Assume, finally, that the functions a_{ij}, b_i, c have the same properties as in Theorem 17, but in $U \cup \{p\}$. Then u is a constant function.

PROOF. Suppose u is not a constant function. Choose $0 < \rho_1 < \rho = d(p, r)$, and let

$$K = \{x : d(x, r) \leq \rho \text{ and } d(x, p) \leq \rho_1\}.$$

Again define

$$v(x) = e^{-kd(r,x)^2} - e^{-k\rho^2}.$$

The boundary of K is the union of a closed set $C \subset U$ and a closed set D on which $v = 0$. Theorem 17 implies (choosing ρ smaller if necessary) that $u(x) < u(p)$ for $x \in C$. So for sufficiently small $\lambda > 0$ we have

$$-\lambda v(x) \geq u(x) - u(p) \quad \text{for } x \in \text{boundary } K.$$

But for sufficiently large k , we have $Lv > 0$ in K . So

$$L(u - u(p) + \lambda v) = Lu - cu(p) + \lambda Lv > 0.$$

It follows from (A) that

$$-\lambda v(x) \geq u(x) - u(p) \quad \text{for all } x \in K.$$

So the directional derivative of u at p , in the direction from p to r , is less than or equal to this directional derivative at p of $-\lambda v$. But we easily compute that the latter directional derivative is

$$-2\lambda k \rho e^{-k\rho^2} < 0,$$

contradicting the hypotheses. ♦

Naturally, there are analogous versions of Corollaries 18 and 19.

PROBLEM

1. (a) Let $f: \mathbb{R}^n \rightarrow \mathbb{R}$ be a C^∞ [respectively, C^ω] function such that $f = 0$ on the points $(0, \dots, 0, x^{n-k+1}, \dots, x^n)$ near 0. Show that there are C^∞ [C^ω] functions h_i near 0 such that

$$f = \sum_{i=1}^k h_i x^i.$$

[The C^ω case is actually trivial; the C^∞ case can be proved by generalizing the argument in the proof of Lemma I.3-2.]

- (b) Let $g: \mathbb{R}^n \rightarrow \mathbb{R}^k$ be a C^∞ [C^ω] function whose Jacobian has rank k on $g^{-1}(0)$, and let $f: \mathbb{R}^n \rightarrow \mathbb{R}$ be a C^∞ [C^ω] function which vanishes on $g^{-1}(0)$. Then near any point of $g^{-1}(0)$ there are C^∞ [C^ω] functions h_i such that

$$f = \sum_{i=1}^k h_i g^i.$$

CHAPTER 11

EXISTENCE AND NON-EXISTENCE OF ISOMETRIC IMBEDDINGS

In the past we have had some very special results about the non-existence of isometric imbeddings of certain Riemannian manifolds in other Riemannian manifolds. For example, a compact surface of everywhere negative curvature cannot be isometrically imbedded, or even immersed, in \mathbb{R}^3 , nor can a complete surface of constant negative curvature be isometrically immersed in \mathbb{R}^3 . Ideally, differential geometry should be replete with such results, so that we could have a reasonable chance of finding the smallest dimensional Euclidean space into which a given Riemannian manifold can be isometrically imbedded. But at present only quite isolated facts are known, and a general theory can hardly be said to exist.

There are, first of all, purely topological, or at any rate differential-topological, questions which have to be considered in any imbedding problem—for there is no point trying to isometrically immerse or imbed a Riemannian manifold in \mathbb{R}^m unless its underlying differentiable manifold has some differentiable immersion or imbedding in \mathbb{R}^m . Generally speaking, the methods used to settle such questions are of little interest to differential geometry *per se*. We note, however, that one special result of this sort has already been proved in Volume I: A compact hypersurface imbedded in \mathbb{R}^m is always orientable (Theorem I.11-14). Thus, for example, there is no imbedding of the projective plane \mathbb{P}^2 in \mathbb{R}^3 . We can supplement this result with a simple differential geometric one: If $\langle \ , \ \rangle$ is a metric on \mathbb{P}^2 with $K > 0$, then $(\mathbb{P}^2, \langle \ , \ \rangle)$ cannot even be isometrically immersed in \mathbb{R}^3 ; this follows directly from Hadamard's Theorem (Theorem 2-11).

At the other extreme from these global topological restrictions, there are certain purely local results. For example, if $n \geq 3$, and M^n has all sectional curvatures < 0 , then M^n cannot be locally isometrically imbedded in \mathbb{R}^{n+1} ; for the principal curvatures k_1, \dots, k_n would have to satisfy $k_i k_j < 0$ for all i, j , while some pair k_i, k_j must have the same sign. Similarly, Theorem 7-50 shows that if $n \geq 3$, and $M^n \subset \mathbb{R}^{n+1}$ has Ricci tensor $\text{Ric} = 0$, then M is flat; so for $n \geq 3$, a non-flat M^n with $\text{Ric} = 0$ is not isometrically imbeddable in \mathbb{R}^{n+1} . Historically, this was first used to show that the 4-dimensional Schwartzschild metric of general relativity is not imbeddable in \mathbb{R}^5 .

To obtain purely local results for higher codimension, we need to replace the trivial algebraic considerations used previously by something more substantial.

1. LEMMA. Let $s: \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}^k$ be a symmetric bilinear map, and let $\langle \cdot, \cdot \rangle$ be a positive definite inner product on \mathbb{R}^k . Let $S^{n-1} \subset \mathbb{R}^n$ be the unit sphere (with respect to the usual inner product $\langle \cdot, \cdot \rangle$ on \mathbb{R}^n), and consider the function $f(x) = |s(x, x)|^2$ for $x \in S^{n-1}$.

(1) If $x \in S^{n-1}$ is a critical point of f , then

$$\langle s(x, x), s(x, y) \rangle = 0 \quad \text{for all } y \text{ with } \langle x, y \rangle = 0.$$

Consequently, if $f(x) \neq 0$, then

$$s(x, y) = 0 \implies \langle x, y \rangle = 0.$$

(2) If $x \in S^{n-1}$ is a minimum point of f , then for all $y \in S^{n-1}$ with $\langle x, y \rangle = 0$ we have

$$\langle s(x, x), s(y, y) \rangle + 2\langle s(x, y), s(x, y) \rangle \geq \langle s(x, x), s(x, x) \rangle.$$

PROOF. (1) Using the fact that the derivative $DA(x)$ of a linear transformation A is always A itself, we easily see that the map $S: \mathbb{R}^n \rightarrow \mathbb{R}^k$ defined by $S(x) = s(x, x)$ has derivative $DS(x): \mathbb{R}^n \rightarrow \mathbb{R}^k$ given by

$$(DS)(x)(y) = 2s(x, y).$$

It follows that

$$(Df)(x)(y) = 2\langle S(x)(y), S(x) \rangle = 4\langle s(x, y), s(x, x) \rangle.$$

Since $x \in S^{n-1}$ is a critical point for f , we must have $(Df)(x)(y) = 0$ for all $y \in S^{n-1}_x$, i.e., for $\langle x, y \rangle = 0$.

Now suppose $s(x, y) = 0$ and $s(x, x) \neq 0$. Writing $y = \lambda x + y'$, with

$$\langle x, y' \rangle = 0 \implies \langle s(x, x), s(x, y') \rangle = 0 \quad \text{by the above paragraph,}$$

we have

$$\begin{aligned} 0 &= \langle s(x, x), s(x, y) \rangle \\ &= \langle s(x, x), s(x, \lambda x) \rangle + \langle s(x, x), s(x, y') \rangle \\ &= \langle s(x, x), s(x, \lambda x) \rangle. \end{aligned}$$

Since $s(x, x) \neq 0$, this implies that $\lambda = 0$.

(2) Let c be the curve in S^{n-1} defined by

$$c(t) = (\cos t)x + (\sin t)y.$$

Since x is a minimum of f we have

$$0 \leq \left. \frac{d^2}{dt^2} \right|_{t=0} f(c(t)).$$

A short computation shows that the right side is

$$4[-\langle s(x, x), s(x, x) \rangle + \langle s(x, x), s(y, y) \rangle + 2\langle s(x, y), s(x, y) \rangle]. \diamond$$

From this we derive, first of all, a purely local result.

2. PROPOSITION. Let N be a manifold of dimension $2n-2$ with all sectional curvatures $\geq K_0$, and let M be a manifold of dimension n with all sectional curvatures $< K_0$. Then M cannot be isometrically immersed in N . The result also holds if all sectional curvatures of N are $> K_0$ and all sectional curvatures of M are $\leq K_0$.

PROOF. Suppose we could isometrically immerse M in N , and let s be the second fundamental form. For any $p \in M$, and orthonormal $X, Y \in M_p$, Gauss' equation gives, under the first hypothesis,

$$\begin{aligned} K_0 &\leq \langle R'(X, Y)Y, X \rangle \\ &= \langle R(X, Y)Y, X \rangle + \langle s(X, Y), s(X, Y) \rangle - \langle s(X, X), s(Y, Y) \rangle \\ &< K_0 + \langle s(X, Y), s(X, Y) \rangle - \langle s(X, X), s(Y, Y) \rangle. \end{aligned}$$

Under the second hypothesis the \leq and $<$ are interchanged. In either case, we obtain

$$(1) \quad \langle s(X, X), s(Y, Y) \rangle - \langle s(X, Y), s(X, Y) \rangle < 0, \quad \begin{array}{l} X, Y \in M_p \\ \text{linearly independent} \end{array}$$

(for this final inequality we do not need X, Y to be orthonormal). Choose $X \in M_p$ to be a minimum point of $X \mapsto |s(X, X)|$ on the unit sphere of M_p . Since $\{Y : s(X, Y) = 0\}$ has dimension ≥ 2 , there is a unit vector Y linearly independent of X with

$$(2) \quad s(X, Y) = 0.$$

From (1) and (2) we see that we must have $s(X, X) \neq 0$. But then Lemma 1(1) implies that $\langle X, Y \rangle = 0$, so Lemma 1(2) gives

$$\langle s(X, X), s(Y, Y) \rangle + 0 \geq \langle s(X, X), s(X, X) \rangle \geq 0,$$

contradicting (1) and (2). \diamond

In particular, an n -manifold M of constant curvature $K < K_0$ cannot be locally isometrically immersed in a $(2n - 2)$ -manifold N of constant curvature K_0 . An example of a (non-complete) n -manifold of constant negative curvature in \mathbb{R}^{2n-1} is given in Problem 1. It seems reasonable to conjecture that there is no immersion of a complete n -manifold of constant negative curvature in \mathbb{R}^{2n-1} , but this has not been proved (whether one can be found in \mathbb{R}^{2n} is any body's guess). It is known, however, that no such immersion exists if M is compact. This follows from the next theorem, whose proof combines the local information from Lemma 1 with just a smidgen of globalness.

3. PROPOSITION. Let N be the complete simply-connected $(2n - 1)$ -dimensional manifold of constant curvature $K_0 \leq 0$, and let M be a compact n -manifold with all sectional curvatures ≤ 0 . Then M cannot be isometrically immersed in N .

PROOF. Suppose there were an isometric immersion $f: M \rightarrow N$. Let $q_0 \in N$ be a fixed point, and choose $p \in M$ so that $f(p)$ is furthest from q_0 . Then (pg. IV.118) there is $\xi \in M_p^\perp$ with

$$(1) \quad \langle s(X, X), \xi \rangle > \sqrt{-K_0} \implies \langle s(X, X), s(X, X) \rangle > -K_0 \quad \text{for } X \in M_p.$$

Choose $X \in M_p$ to be the minimum point of $X \mapsto |s(X, X)|^2$ on the unit sphere in M_p . Since $\{Y : s(X, Y) = 0\}$ has dimension ≥ 1 , there is a unit vector $Y \in M_p$ with

$$(2) \quad s(X, Y) = 0 \implies \langle X, Y \rangle = 0 \quad \text{by Lemma 1(1).}$$

Then Lemma 1(2) gives

$$(3) \quad \langle s(X, X), s(Y, Y) \rangle \geq \langle s(X, X), s(X, X) \rangle > -K_0, \quad \text{by (1).}$$

Moreover, applying Gauss' equation to the plane $P \subset M_p$ spanned by the orthonormal vectors X, Y , we have

$$\begin{aligned} K(P) &= \langle s(X, X), s(Y, Y) \rangle - \langle s(X, Y), s(X, Y) \rangle + K_0 \\ &> -K_0 + 0 + K_0 \quad \text{by (2) and (3).} \end{aligned}$$

This contradicts the assumption that $K(P) \leq 0$. ♦

Remark: More generally, if each tangent space M_p contains an l -dimensional subspace on which all sectional curvatures are ≤ 0 , and the compact manifold M can be isometrically immersed in the complete simply-connected $(n+k)$ -dimensional manifold of sectional curvature $K_0 \leq 0$, then we must have $k \geq l$. Proposition 2 can be generalized similarly.

4. COROLLARY (TOMPKINS). An n -dimensional compact flat Riemannian manifold cannot be isometrically immersed in \mathbb{R}^{2n-1} .

Obviously $2n - 1$ is the best possible dimension here, since the flat n -torus $S^1 \times \cdots \times S^1$ is isometrically imbedded in \mathbb{R}^{2n} . It is also isometrically imbedded in $H^{2n}(K_0)$ for any $K_0 < 0$, since it is isometrically imbedded in S^{2n-1} , and there are spheres of all curvatures in $H^{2n}(K_0)$. I do not know if there is a non-flat compact n -manifold in \mathbb{R}^{2n} or $H^{2n}(K_0)$ with all sectional curvatures ≤ 0 .

The proof of Proposition 3 breaks down if N is a sphere, with constant curvature $K_0 > 0$, since we cannot guarantee the existence of the requisite point $p \in M$ unless we know that M lies in a hemisphere. Indeed, the n -dimensional flat torus $S^1 \times \cdots \times S^1$ can be isometrically imbedded in S^{2n-1} . It seems reasonable to assume that M^n cannot be isometrically immersed in S^{2n-1} if all sectional curvatures of M are > 0 and < 1 . For the special case where M has constant curvature, see Problem 2.

Now we are going to consider some more elaborate algebraic results. Let V be a real vector space, and let $\Phi: V \times V \rightarrow \mathbb{R}$ be bilinear. With Φ we can associate a linear transformation $\tilde{\Phi}: V \rightarrow V^*$ by

$$\tilde{\Phi}(v)(w) = \Phi(v, w).$$

A collection Φ^1, \dots, Φ^n of bilinear forms on V is called **exteriorly orthogonal** if for all $v_1, v_2 \in V$ we have

$$\sum_{i=1}^n \tilde{\Phi}^i(v_1) \wedge \tilde{\Phi}^i(v_2) = 0 \in \Omega^2(V);$$

equivalently,

$$\sum_{i=1}^n [\Phi^i(v_1, w_1) \Phi^i(v_2, w_2) - \Phi^i(v_1, w_2) \Phi^i(v_2, w_1)] = 0$$

for all $v_1, v_2, w_1, w_2 \in V$. Before stating the main result about exteriorly orthogonal bilinear forms, we make a simple observation. If $\Phi \neq 0$ is $\Phi = \phi \otimes \phi$ for some $\phi \in V^*$, so that $\Phi(v, w) = \phi(v) \cdot \phi(w)$, then $\tilde{\Phi}(v) = \phi(v) \cdot \phi$, and consequently $\text{range } \tilde{\Phi} \subset V^*$ is 1-dimensional. Conversely, if $\text{range } \tilde{\Phi} \subset V^*$ is 1-dimensional, then $\tilde{\Phi}$ must be of the form

$$\tilde{\Phi}(v)(w) = \psi(v) \cdot \phi(w)$$

for $\phi, \psi \in V^*$. If, moreover, $\tilde{\Phi}$ is symmetric, so that $\psi(v) \cdot \phi(w) = \psi(w) \cdot \phi(v)$ for all v, w , then we must have $\phi = \psi$ [since $(\phi - \psi)(w) = 0$ for some $w \neq 0$], so Φ is of the form $\Phi = \phi \otimes \phi$.

5. THEOREM (É. CARTAN). Let V be a real vector space of dimension n , and let Φ^1, \dots, Φ^n be n exteriorly orthogonal symmetric bilinear forms on V . Suppose that

$$(*) \quad 0 = \bigcap_{i=1}^n \ker \tilde{\Phi}^i = \{v \in V : \Phi^i(v, w) = 0 \text{ for all } v \in V \text{ and all } i\}.$$

Then there is an orthogonal $n \times n$ matrix A and linearly independent $\phi^1, \dots, \phi^n \in V^*$ such that

$$\Phi^i = \sum_{j=1}^n A_j^i \phi^j \otimes \phi^j.$$

PROOF. We claim that there is a vector $v \in V$ such that the $\tilde{\Phi}^i(v) \in V^*$ are linearly independent. To prove this, let $v_0 \in V$ be a vector such that the subspace

$$[\tilde{\Phi}^1(v_0), \dots, \tilde{\Phi}^n(v_0)] \subset V^*$$

spanned by the $\tilde{\Phi}^i(v_0)$ has maximal dimension $d \leq n$, and suppose that $d < n$. Replacing the $\{\tilde{\Phi}^i\}$ by an orthogonal linear combination of them changes neither the hypotheses nor the conclusion of the theorem, so without loss of generality we can assume that

$$\begin{aligned} \tilde{\Phi}^1(v_0), \dots, \tilde{\Phi}^d(v_0) &\text{ are linearly independent,} \\ \tilde{\Phi}^{d+1}(v_0) &= \dots = \tilde{\Phi}^n(v_0) = 0. \end{aligned}$$

Then for any vector $v \in V$ we have

$$\sum_{i=1}^d \tilde{\Phi}^i(v_0) \wedge \tilde{\Phi}^i(v) = 0.$$

Cartan's Lemma thus implies that for $i = 1, \dots, d$, the $\tilde{\Phi}^i(v)$ are a linear combination of the $\tilde{\Phi}^i(v_0)$, $i = 1, \dots, d$. Consequently

$$\mathcal{V} = \{\tilde{\Phi}^i(v) : v \in V, 1 \leq i \leq d\} \subset V^*$$

also has dimension exactly d . Since $d < n$, there is a vector $0 \neq w \in V$ such that $\phi(w) = 0$ for all $\phi \in \mathcal{V}$. But by $(*)$ there is some i and some $v \in V$ such that $\Phi^i(v, w) \neq 0$; clearly $i > d$. Now consider the vector $v_0 + \varepsilon v$. If $\varepsilon > 0$ is sufficiently small, then

$$\dim[\tilde{\Phi}^1(v_0 + \varepsilon v), \dots, \tilde{\Phi}^d(v_0 + \varepsilon v)] = \dim[\tilde{\Phi}^1(v_0), \dots, \tilde{\Phi}^d(v_0)] = d$$

$$\Downarrow$$

$$[\tilde{\Phi}^1(v_0 + \varepsilon v), \dots, \tilde{\Phi}^d(v_0 + \varepsilon v)] = \mathcal{V}, \quad \text{since } \dim \mathcal{V} = d.$$

But $\tilde{\Phi}^i(v_0 + \varepsilon v) \notin \mathcal{V}$, by the choice of v and i . So

$$\dim[\tilde{\Phi}^1(v_0 + \varepsilon v), \dots, \tilde{\Phi}^n(v_0 + \varepsilon v)] > d,$$

contradicting the definition of d . This establishes the claim.

Now choose a basis v_1, \dots, v_n of V such that $\tilde{\Phi}^1(v_1), \dots, \tilde{\Phi}^n(v_1)$ are linearly independent. Since

$$\sum_{i=1}^n \tilde{\Phi}^i(v_1) \wedge \tilde{\Phi}^i(v_j) = 0,$$

Cartan's Lemma implies that there is a symmetric matrix $C(j)$, with $C(1) =$ identity, such that

$$\tilde{\Phi}^i(v_j) = \sum_{h=1}^n C(j)_h^i \tilde{\Phi}^h(v_1).$$

The equation

$$\sum_h \tilde{\Phi}^h(v_j) \wedge \tilde{\Phi}^h(v_k) = 0$$

implies that $C(j)$ and $C(k)$ commute. Then a well-known theorem of linear algebra (Problem 3) states that there is an orthogonal matrix B such that the matrices $B \cdot C(i) \cdot B^t$ are diagonal for all i , where t denotes the transpose. If we set

$$\Psi^i = \sum_h B_h^i \Phi^h,$$

then $\tilde{\Psi}^i(v_j)$ is a constant times $\tilde{\Psi}^i(v_1)$. Thus range $\tilde{\Psi}^i$ is 1-dimensional, so $\Psi^i = \phi^i \otimes \phi^i$ for some $\phi^i \in V^*$. We choose $A = B^{-1}$. The ϕ^i must be linearly independent, for otherwise there is $0 \neq v \in V$ such that $\phi^i(v) = 0$ for all i , contradicting (*). ♦

The hypothesis (*) in Theorem 5 may be interpreted as saying that the set $\{\Phi^i\}$ "depends on n variables"—we cannot find $\phi^1, \dots, \phi^{n-1} \in V^*$ such that each Φ^i is a linear combination of the $\phi^j \otimes \phi^k$, $1 \leq j, k \leq n-1$. More generally, if Φ^1, \dots, Φ^k are bilinear forms on V , then the set $\{\Phi^i\}$ **depends on q variables** if the subspace $\bigcap_{i=1}^k \ker \tilde{\Phi}^i$ has codimension q .

6. COROLLARY. Let V be a real vector space of dimension n , and let Φ^1, \dots, Φ^k be k exteriorly orthogonal symmetric bilinear forms on V which depend on

$l \geq k$ variables (so necessarily $k \leq n$). Then $l = k$ and there is an orthogonal $k \times k$ matrix A and linearly independent $\phi^1, \dots, \phi^k \in V^*$ such that

$$\Phi^i = \sum_{j=1}^k A_j^i \phi^j \otimes \phi^j.$$

In particular, k exteriorly orthogonal symmetric bilinear forms always depend on $\leq k$ variables.

PROOF. Without loss of generality, we can assume that $l = n$ [by applying the result to a subspace of V complementary to $\bigcap_{i=1}^k \ker \tilde{\Phi}^i$]. If $k < l = n$, we set

$$\Phi^{k+1} = \dots = \Phi^n = 0.$$

The n bilinear forms Φ^1, \dots, Φ^n are then exteriorly orthogonal and $\bigcap_{i=1}^n \ker \tilde{\Phi}^i = 0$. By the Theorem, there is an orthogonal $n \times n$ matrix A , and linearly independent $\phi^1, \dots, \phi^n \in V^*$ with

$$\Phi^i = \sum_{j=1}^n A_j^i \phi^j \otimes \phi^j.$$

So we cannot have $\Phi^i = 0$ for any i , which shows that actually $k = n = l$. ♦

These algebraic results were used by Cartan for a systematic local study of n -dimensional manifolds M of constant curvature K isometrically imbedded in an $(n + k)$ -dimensional manifold N of constant curvature $K_0 > K$. For an adapted orthonormal moving frame X_1, \dots, X_m on $M \subset N$ we have, as in Chapter 1,

$$\psi_j^r = \sum_i s_{ij}^r \theta^i, \quad s_{ij}^r = s_{ji}^r;$$

the second fundamental forms Π^r are given by

$$\Pi^r = \sum_i \psi_i^r \otimes \theta^i.$$

We also have

$$\begin{aligned} K_0 \theta^i \wedge \theta^j &= \Omega_j^i - \sum_r \psi_i^r \wedge \psi_j^r \\ &= K \theta^i \wedge \theta^j - \sum_r \psi_i^r \wedge \psi_j^r, \end{aligned}$$

or equivalently

$$(1) \quad \sum_r (s_{ij}^r s_{kl}^r - s_{il}^r s_{kj}^r) = (K - K_0)(\delta_{ij}\delta_{kl} - \delta_{il}\delta_{kj}).$$

If we define

$$\Psi = \sqrt{K_0 - K} \left(\sum_i \theta^i \otimes \theta^i \right),$$

then equation (1) says that the $k + 1$ bilinear forms $\{\Pi^r, \Psi\}$ are exteriorly orthogonal. The collection $\{\Pi^r, \Psi\}$ certainly depends on all n variables, since Ψ alone does. So Corollary 6 implies that $n \leq k + 1$, showing once again that M^n cannot be isometrically imbedded in N^{2n-2} . Cartan showed, using his theory of exterior differential systems (Chapter 10, Addendum 1) that the analytic local imbeddings of M^n in N^{2n-1} depend upon $n(n - 1)$ functions of one variable.

Another consequence of Corollary 6 depends on two definitions, one intrinsic and one extrinsic. For a point p of a Riemannian manifold M^n , we define the **index of nullity** at p to be

$$\mu(p) = \dim\{X \in M_p : R(X, Y) = 0 \text{ for all } Y \in M_p\}.$$

Equivalently, $n - \mu(p)$ is the minimum number of 1-forms in terms of which we can express the collection of 2-forms $\{\Omega_j^i(p)\}$. For $M^n \subset \mathbb{R}^{n+k}$, with second fundamental form s , we define the **index of relative nullity** at p to be

$$\begin{aligned} \nu(p) &= \dim\{X \in M_p : A_\xi(X) = 0 \text{ for all } \xi \in M_p^\perp\} \\ &= \dim\{X \in M_p : s(X, Y) = 0 \text{ for all } Y \in M_p\}. \end{aligned}$$

Equivalently, $n - \nu(p)$ is the minimum number of 1-forms in terms of which we can express the collection of forms $\{\Pi^r(p)\}$, for an orthonormal set $\nu^{n+1}, \dots, \nu^{n+k} \in M_p^\perp$.

7. PROPOSITION. For $M^n \subset \mathbb{R}^{n+k}$ we have

$$\nu(p) \leq \mu(p) \leq \nu(p) + \text{rank } s(p) \leq \nu(p) + k.$$

PROOF. The first inequality follows from Gauss' equation, which shows that

$$\begin{aligned} \{X \in M_p : s(X, Y) = 0 \text{ for all } Y \in M_p\} \\ \subset \{X \in M_p : R(X, Y) = 0 \text{ for all } Y \in M_p\}. \end{aligned}$$

For the second we can assume, by choosing the v^r appropriately, that $\Pi^{n+1}(p), \dots, \Pi^{n+d}(p)$ are linearly independent, for $d = \text{rank } s(p)$, while the other $\Pi^r(p)$ are all 0. Then Gauss' equation shows that $\Pi^{n+1}(p), \dots, \Pi^{n+d}(p)$ are exteriorly orthogonal when restricted to $\{X \in M_p : R(X, Y) = 0 \text{ for all } Y \in M_p\}$. Let W be a subspace such that

$$\begin{aligned} \{X \in M_p : R(X, Y) = 0 \text{ for all } Y \in M_p\} \\ = W \oplus \{X \in M_p : s(X, Y) = 0 \text{ for all } Y \in M_p\}. \end{aligned}$$

Then $\Pi^{n+1}(p), \dots, \Pi^{n+d}(p)$ are exteriorly orthogonal on W , and depend on all variables of W . Corollary 6 implies that $d \geq \dim W = v(p) - \mu(p)$. ♦

Remark: We have a similar result for $M^n \subset N^{n+k}$, where N^{n+k} has constant curvature K_0 , provided we redefine

$$\mu(p) = \dim\{X \in M_p : R(X, Y)Z = K_0[\langle Y, Z \rangle X - \langle X, Z \rangle Y]\}.$$

8. COROLLARY. If M^n is a compact manifold immersed in \mathbb{R}^{n+k} , then

$$k \geq \min_{p \in M} \mu(p).$$

PROOF. Proposition 7-30 shows that for some $p \in M$ we have $v(p) = 0$. ♦

Note that Corollary 4 is a special case (admittedly the only reasonably general consequence we can give). Recently Corollary 6 has been used to prove results of quite another sort, which we will mention in the next chapter.

This ends our treatment of non-imbeddability theorems, and pretty much exhausts the subject in its present state (a few other special results are mentioned in the Bibliography). Now we will take a more positive approach to life and try to prove that under certain circumstances isometric imbeddings do exist. We first consider the purely local problem of isometrically imbedding a surface in \mathbb{R}^3 . So we assume that we are given functions g_{ij} ($= E, F, G$) on a neighborhood of $0 \in \mathbb{R}^2$, with $\det(g_{ij}) > 0$, and we want to find a function $f : U \rightarrow \mathbb{R}^3$, on some smaller neighborhood U of $0 \in \mathbb{R}^2$, such that $I_f = f^*(\langle \cdot, \cdot \rangle)$ has components g_{ij} . This means that the component functions f^α of f must satisfy

$$g_{ij} = \sum_{\alpha=1}^3 \langle f^\alpha_i, f^\alpha_j \rangle,$$

so that we have three (non-linear) partial differential equations in three unknowns. We also know that f can be found once we have functions l_{ij} satisfying Gauss' equation and the Codazzi-Mainardi equation, which again gives us three equations in three unknowns. There is also a way of introducing a single second order equation, which was used classically. Suppose that the required f exists; let N be its normal map, and let l_{ij} be the components of Π_f . Then for each component function f^α of f we have the Gauss formulas

$$(1) \quad \begin{aligned} f^\alpha_{11} - \Gamma_{11}^1 f^\alpha_1 - \Gamma_{11}^2 f^\alpha_2 &= l_{11} N^\alpha \\ f^\alpha_{12} - \Gamma_{12}^1 f^\alpha_1 - \Gamma_{12}^2 f^\alpha_2 &= l_{12} N^\alpha \\ f^\alpha_{22} - \Gamma_{22}^1 f^\alpha_1 - \Gamma_{22}^2 f^\alpha_2 &= l_{22} N^\alpha. \end{aligned}$$

If we denote these component functions of f by u, v, w , then

$$\begin{aligned} N &= \frac{f_1 \times f_2}{\sqrt{\det(g_{ij})}} = \frac{(u_1, v_1, w_1) \times (u_2, v_2, w_2)}{\sqrt{\det(g_{ij})}} \\ &= \frac{(v_1 w_2 - v_2 w_1, w_1 u_2 - u_1 w_2, u_1 v_2 - u_2 v_1)}{\sqrt{\det(g_{ij})}}. \end{aligned}$$

So, for example, the third component N^3 of N satisfies

$$\begin{aligned} \det(g_{ij}) \cdot (N^3)^2 &= (u_1 v_2 - u_2 v_1)^2 \\ &= (u_1^2 + v_1^2)(u_2^2 + v_2^2) - (u_1 u_2 + v_1 v_2)^2 \\ &= (g_{11} - w_1^2)(g_{22} - w_2^2) - (g_{12} - w_1 w_2)^2 \\ &= \det(g_{ij}) - (g_{22} w_1^2 - 2g_{12} w_1 w_2 + g_{11} w_2^2). \end{aligned}$$

Using equations (1) for $\alpha = 3$, we obtain

$$\begin{aligned} (*) \quad &(w_{11} - \Gamma_{11}^1 w_1 - \Gamma_{11}^2 w_2)(w_{22} - \Gamma_{22}^1 w_1 - \Gamma_{22}^2 w_2) - (w_{12} - \Gamma_{12}^1 w_1 - \Gamma_{12}^2 w_2)^2 \\ &= (l_{11} l_{22} - l_{12}^2) \cdot \frac{\{\det(g_{ij}) - (g_{22} w_1^2 - 2g_{12} w_1 w_2 + g_{11} w_2^2)\}}{\det(g_{ij})} \\ &= K \{\det(g_{ij}) - (g_{22} w_1^2 - 2g_{12} w_1 w_2 + g_{11} w_2^2)\}, \end{aligned}$$

where the Γ 's and K are all computable in terms of the g_{ij} . We thus have a certain non-linear second order partial differential equation (*) for w . Notice that this equation does not contain w explicitly. If w is any solution, then so is $w + \text{constant}$, so we can always specify $w(0)$ arbitrarily.

It is easily checked (and is *a priori* clear on symmetry grounds) that u and v also satisfy equation (*). On the other hand, it is by no means true that (u, v, w) is a solution of our problem whenever u, v, w each satisfy (*), even if (u, v, w) is an immersion. In order to obtain more precise information, we must use a different procedure, due to Darboux. Suppose first that we are given an immersion $f = (u, v, w)$ such that I_f has components E, F, G ; thus

$$(1) \quad du \otimes du + dv \otimes dv + dw \otimes dw = E dx \otimes dx + F[dx \otimes dy + dy \otimes dx] + G dy \otimes dy,$$

where (x, y) is the standard coordinate system on \mathbb{R}^2 . By composing f with a Euclidean motion, if necessary, we can assume that

$$(2) \quad w_1(0, 0) = w_2(0, 0) = 0$$

$$\Downarrow$$

$$(3) \quad \begin{pmatrix} u_1 & u_2 \\ v_1 & v_2 \end{pmatrix} \text{ is nonsingular at } (0, 0).$$

Consider the tensor

$$\begin{aligned} \langle \cdot, \cdot \rangle' &= E dx \otimes dx + F[dx \otimes dy + dy \otimes dx] + G dy \otimes dy - dw \otimes dw \\ &= (E - w_1^2) dx \otimes dx + (F - w_1 w_2)[dx \otimes dy + dy \otimes dx] \\ &\quad + (G - w_2^2) dy \otimes dy. \end{aligned}$$

Using (1) we can write

$$(4) \quad \langle \cdot, \cdot \rangle' = du \otimes du + dv \otimes dv.$$

This is positive definite at $(0, 0)$ by (2), and hence positive definite in a neighborhood of $(0, 0)$. Moreover, (u, v) is a coordinate system for \mathbb{R}^2 in a neighborhood of $(0, 0)$, by (3). So equation (4) says that $\langle \cdot, \cdot \rangle'$ is flat, and thus has curvature $K' = 0$.

Recall (pg. II.131) that the metric with coefficients E, F, G has curvature K given by

$$(5) \quad K(EG - F^2)^2 = \det \begin{pmatrix} -\frac{1}{2}G_{11} + F_{12} - \frac{1}{2}E_{22} & \frac{1}{2}E_1 & F_1 - \frac{1}{2}E_2 \\ F_2 - \frac{1}{2}G_1 & E & F \\ \frac{1}{2}G_2 & F & G \end{pmatrix} \\ - \det \begin{pmatrix} 0 & \frac{1}{2}E_2 & \frac{1}{2}G_1 \\ \frac{1}{2}E_2 & E & F \\ \frac{1}{2}G_1 & F & G \end{pmatrix}.$$

To obtain the condition $K' = 0$, we set the right side equal to 0 after replacing E by $E - w_1^2$, etc. With the standard notation

$$\begin{aligned} p &= w_1, & q &= w_2, \\ r &= w_{11}, & s &= w_{12}, & t &= w_{22}, \end{aligned}$$

the (1, 1) term in the first matrix becomes

$$-\frac{1}{2}(G - w_2^2)_{11} + (F - w_1 w_2)_{12} - \frac{1}{2}(E - w_1^2)_{22} = -\frac{1}{2}G_{11} + F_{12} - \frac{1}{2}E_{22} + (s^2 - rt),$$

all third derivatives canceling. We thus obtain a second order equation for w , the “Darboux equation”, which written out explicitly becomes

$$\begin{aligned}
 (**) \quad 0 = & -4(EG - F^2)(rt - s^2) \\
 & + 2pr[2GF_2 - GG_1 - FG_2] + 2qr[EG_2 + FG_1 - 2FF_2] \\
 & + 4ps[FG_1 - GE_2] + 4qs[FE_2 - EG_1] \\
 & + 2pt[GE_1 + FE_2 - 2FF_1] + 2qt[2EF_1 - EE_2 - FE_1] \\
 & + (E - p^2)[E_2G_2 - 2F_1G_2 + (G_1)^2] \\
 & + (F - pq)[E_1G_2 - E_2G_1 - 2E_2F_2 - 2G_1F_1 + 4F_1F_2] \\
 & + (G - q^2)[G_1E_1 - 2F_2E_1 + (E_2)^2] \\
 & + 2[EG - F^2 - Gp^2 - Eq^2 + 2Fpq] \cdot [2F_{12} - E_{22} - G_{11}].
 \end{aligned}$$

Brute force computations will show that equations (*) and (**) are, in fact, the same (a somewhat more refined approach is given in Problem 4). But our derivation of (**) now enables us to relate solutions of (**) with functions $f = (u, v, w)$ satisfying (1). For suppose that w is a solution of (**) satisfying (2). Then $\langle \cdot, \cdot \rangle'$ is positive definite, and has curvature $K' = 0$. So there is a coordinate system (u, v) satisfying (4), which implies that (u, v, w) satisfies (1). The possible coordinate systems (u, v) for the flat metric $\langle \cdot, \cdot \rangle'$ all differ by a Euclidean motion of \mathbb{R}^2 , so (u, v) is determined by specifying

$$\begin{aligned}
 & u(0), \quad v(0), \\
 & u_1(0), \quad u_2(0), \quad v_1(0), \quad v_2(0),
 \end{aligned}$$

where the $u_i(0)$ and $v_i(0)$ have to be chosen so that (1) holds at $(0, 0)$. Notice that u and v will automatically satisfy (**), since this equation is equivalent to (*), which is satisfied by all component functions $f = (u, v, w)$ satisfying (1). We thus have the paradoxical situation that u, v, w all satisfy $(**) \equiv (*)$, but that once we pick the initial conditions w_1, w_2 along the x -axis which determine w , then we have almost no choice left for the initial conditions for u and v ; of course, we could just as well pick the initial conditions for u , say, and then be stuck with those for v and w .

The Darboux equation is not linear, but it is linear in $(rt - s^2)$, r, s, t ; as we mentioned in Chapter 10, section 8, equations of this sort are called “Monge-Ampère equations”. We can write our equation as

$$t(r + Ap + Bq) + C = 0,$$

where A, B, C do not involve t , and thus we can solve for t in terms of the other quantities,

$$(6) \quad t = \frac{-C}{r + Ap + Bq} = g(x, y, p, q, r, s).$$

More precisely, if we are given initial conditions along the x -axis such that $Ap + Bq + r \neq 0$ at $(0, 0)$, then we can write our equation in this form near $(0, 0)$. In Chapter 10, Part 4, we showed that the Cauchy problem for such an equation is equivalent to the Cauchy problem for a quasi-linear first order system, which can always be solved, by the Cauchy-Kowalewski theorem, if all functions in the equation, and the initial data, are analytic. Thus we see that the required isometric imbedding f exists locally if E, F, G are analytic.

Naturally we would like to know to what extent this restriction to analytic E, F, G and analytic initial data is necessary. Recall that a solution w of a second order PDE

$$F(x, y, w, p, q, r, s, t) = 0$$

is elliptic [respectively, hyperbolic] if and only if

$$4F_r F_t - F_s^2 > 0 \quad [\text{respectively, } < 0].$$

We consider the Darboux equation in the form (*) on page 143. Our condition becomes

$$4(w_{22} - \Gamma_{22}^1 w_1 - \Gamma_{22}^2 w_2)(w_{11} - \Gamma_{11}^1 w_1 - \Gamma_{11}^2 w_2) - 4(w_{12} - \Gamma_{12}^1 w_1 - \Gamma_{12}^2 w_2)^2 > 0 \quad [\text{respectively, } < 0].$$

Using equations (1) on page 143, this becomes

$$(N^3)^2(l_{22}l_{11} - l_{12}^2) > 0 \quad [\text{respectively, } < 0].$$

So at all points where $N^3 \neq 0$, the solution w is elliptic [hyperbolic] if and only if the corresponding surface (obtained by choosing u, v as before) has $K > 0$ [$K < 0$]. Thus the cases $K > 0$ and $K < 0$ require separate treatment.

We note first that Theorem 10-13 shows that if $K > 0$ everywhere and E, F, G are analytic, then every imbedding f such that I_f has components E, F, G is automatically analytic, so there is no point considering initial data which are not analytic. Expressed somewhat differently, if a surface $M \subset \mathbb{R}^3$ has $K > 0$ everywhere and a metric which is analytic in *some* coordinate system, then M is actually an analytic submanifold of \mathbb{R}^3 . In particular, if M is *any* (C^3) surface of constant positive curvature, then M is automatically analytic.

When E, F, G are not analytic, there is no known criterion on the initial data which will guarantee the existence of a solution of the Darboux equation (**). However, we might simply ask if there is *some* solution of the Darboux equation (without specifying initial conditions), and hence some imbedding f such that I_f has components E, F, G . The fact that a second order equation like (**) actually has solutions has been “known” for a long time—an actual proof may be found in Jacobowitz [1].

When $K < 0$ there is no problem. Theorem 10-12 shows that for any initial conditions with $F_t = r + Ap + Bq \neq 0$, there is always a solution w of (**) in a neighborhood of $(0, 0)$, and we can obtain solutions less differentiable than the functions E, F, G . (In the next chapter we will have occasion to examine the case where the initial conditions are such that $F_t = 0$.) We see, in particular, that there are surfaces of constant negative curvature in \mathbb{R}^3 which are C^∞ , but not analytic.

By the way, it is interesting to note that a surface of constant *mean* curvature H is always analytic (the sign of H couldn't be relevant, since it is not even well-determined). For suppose that $M \subset \mathbb{R}^3$ is a surface with $H = C$, given locally as the graph of a function h . Then formula (B') on pg. III.137 gives

$$\begin{aligned} 0 &= F(x, y, h, p, q, r, s, t) \\ &= (1 + q^2)r - 2pq s + (1 + p^2)t - 2C(1 + p^2 + q^2)^{3/2}, \end{aligned}$$

so

$$4F_r F_t - F_s^2 = 4[(1 + q^2)(1 + p^2) - p^2 q^2] = 4(1 + p^2 + q^2) > 0,$$

and h is analytic by Theorem 10-13.

We now consider the general problem of locally imbedding an n -manifold in \mathbb{R}^m . We are given g_{ij} on a neighborhood of $0 \in \mathbb{R}^n$, and we seek $f: U \rightarrow \mathbb{R}^m$, on some smaller neighborhood U , such that

$$\begin{aligned} (1) \quad g_{ij} &= \langle f_i, f_j \rangle \\ &= \sum_{\alpha=1}^m \langle f^\alpha_i, f^\alpha_j \rangle = \sum_{\alpha=1}^m \frac{\partial f^\alpha}{\partial x_i} \cdot \frac{\partial f^\alpha}{\partial x_j}. \end{aligned}$$

Since this is a set of $s_n = n(n+1)/2$ equations, it seems unlikely that we can always find f if $m < s_n$. In fact, if (1) is to hold, then all equations obtained from (1) by partial differentiation must also hold. If we evaluate these equations at 0, we obtain polynomial formulas expressing the derivatives

$$(2) \quad \frac{\partial^{r_1+\dots+r_n} g_{ij}}{\partial^{r_1} x_1 \dots \partial^{r_n} x_n} (0) \quad 0 \leq r_1 + \dots + r_n \leq r-1$$

in terms of the derivatives

$$(3) \quad \frac{\partial^{r_1+\dots+r_n} f^\alpha}{\partial^{r_1} x_1 \dots \partial^{r_n} x_n}(0) \quad 1 \leq r_1 + \dots + r_n \leq r.$$

For each g_{ij} , the number of derivatives in (2) is the binomial coefficient $\binom{n+r-1}{n}$ [= the number of ways of picking n things from $n+r-1$ things], for we can associate to each set $\alpha_1 < \alpha_2 < \dots < \alpha_n$ of integers from 1 to $n+r-1$ the numbers

$$r_1 = \alpha_1 - 1, \quad r_2 = \alpha_2 - \alpha_1 - 1, \quad \dots, \quad r_n = \alpha_n - \alpha_{n-1} - 1.$$

Thus,

$$\# \text{ of derivatives in (2) is } a = s_n \cdot \binom{n+r-1}{n}.$$

Similarly,

$$\# \text{ of derivatives in (3) is } b = m \cdot \left[\binom{n+r}{n} - 1 \right].$$

Now if $m < s_n$, then the first of these numbers will be greater than the second for large enough r . In fact,

$$(s_n - 1) \cdot \frac{(n+r)!}{n!r!} = s_n \cdot \frac{(n+r-1)!}{n!(r-1)!} \quad \text{for } r = n(s_n - 1).$$

But this means that the set of all possible derivatives (2), considered as a point in \mathbb{R}^a , is the image of a polynomial map defined on a lower dimensional space \mathbb{R}^b , so the derivatives (2) cannot be assigned arbitrarily for a map $f: \mathbb{R}^n \rightarrow \mathbb{R}^m$, $m < s_n$. In other words, not every g_{ij} can be obtained from some f .

It also seems reasonable to conjecture that we can always find an appropriate f when $m = s_n$. With the proper handling of subsidiary considerations, the proof of this conjecture can be reduced to the Cauchy-Kowalewski theorem (which means that we will have to assume that the g_{ij} are analytic). First a preliminary definition. Given $f: U \rightarrow \mathbb{R}^m$, consider the space spanned by the vectors

$$\frac{\partial f}{\partial x^i} \quad 1 \leq i \leq n, \quad \frac{\partial^2 f}{\partial x^i \partial x^j} \quad 1 \leq i, j \leq n$$

at a point $p \in U$ [this is the direct sum of the tangent space of $f(U)$ at $f(p)$ and the first normal space at $f(p)$, in the terminology of Addendum 4 to Chapter 7]. The map f is called **non-degenerate** if these $n + s_n$ vectors are linearly independent, for each $p \in U$. For example, a curve in $\mathbb{R}^2 \subset \mathbb{R}^m$ is non-degenerate if its curvature is nowhere zero.

9. THEOREM (BURSTIN-JANET-CARTAN). Let g_{ij} be the components of an analytic Riemannian metric in a neighborhood of $0 \in \mathbb{R}^n$. Then there is an analytic isometric imbedding $f: U \rightarrow \mathbb{R}^{s_n}$ (defined on some smaller neighborhood U).

PROOF. Let V_i be i -dimensional subspaces of \mathbb{R}^n_0 with

$$V_1 \subset \cdots \subset V_n = \mathbb{R}^n_0,$$

and let

$$H_i = \exp_0(V_i) \subset \mathbb{R}^n$$

(the exponential map being defined with respect to the metric given by the g_{ij}). Since H_1 is a curve, we can clearly find an analytic isometric imbedding $f_1: H_1 \rightarrow \mathbb{R}^{s_n}$; moreover, we can arrange for f_1 to be non-degenerate. We will now show that if $f_k: H_k \rightarrow \mathbb{R}^{s_n}$ is a free analytic isometric imbedding, then f_k can be extended to an analytic isometric imbedding $f_{k+1}: H_{k+1} \rightarrow \mathbb{R}^{s_n}$ (defined perhaps in a smaller neighborhood of 0). Moreover, for $k+1 < n$ we will show that f_{k+1} can be chosen to be non-degenerate [note that $l < n \implies l + s_l < s_n$]. This will clearly prove the theorem.

Step 1. By changing our coordinate system $x_1, \dots, x_k, y = x_{k+1}$ on H_{k+1} we can assume that

$$\begin{aligned} H_k &= \{(x, y) : y = 0\} \\ g_{i,k+1} &= 0 \quad (1 \leq i \leq k), \quad g_{k+1,k+1} = 1. \end{aligned}$$

Then the equations $g_{ij} = \langle f_i, f_j \rangle$ become

$$\begin{aligned} (1) \quad & \langle f_{x_i}, f_{x_j} \rangle = g_{ij} \\ & \langle f_{x_i}, f_y \rangle = 0 \\ & \langle f_y, f_y \rangle = 1. \end{aligned}$$

Differentiating the first equation with respect to y , and the second with respect to x_j , we find that if f satisfies (1), then it also satisfies the following set of equations, which are of first order with respect to the y variable:

$$(2a) \quad \langle f_y, f_{x_i x_j} \rangle = -\frac{1}{2}(g_{ij})_y$$

$$(2b) \quad \langle f_y, f_{x_i} \rangle = 0$$

$$(2c) \quad \langle f_y, f_y \rangle = 1.$$

Similar manipulations show that f also satisfies the equations

$$(3a) \quad \langle f_{yy}, f_{x_i} \rangle = 0$$

$$(3b) \quad \langle f_{yy}, f_y \rangle = 0$$

$$(3c) \quad \langle f_{yy}, f_{x_i x_j} \rangle = -\frac{1}{2}(g_{ij})_{yy} + \langle f_{yx_i}, f_{yx_j} \rangle,$$

which are of second order with respect to the y variables.

Conversely, suppose that f satisfies (3), and also satisfies (2) on H_k . We claim that f satisfies (1). First of all, since (3b) says that $\langle f_y, f_y \rangle_y = 0$, equation (2c) on H_k implies that $\langle f_y, f_y \rangle = 1$ everywhere. Consequently, we also have $\langle f_y, f_{x_i y} \rangle = 0$. So (3a) says that $\langle f_{x_i}, f_y \rangle_y = 0$, and then (2b) on H_k implies that $\langle f_{x_i}, f_y \rangle = 0$. Thus we have the last two equations of (1). Now from

$$\langle f_{x_i}, f_y \rangle = 0, \quad \langle f_{x_j}, f_y \rangle = 0, \quad \langle f_y, f_y \rangle = 1$$

we obtain

$$(i) \quad \langle f_{x_i x_j}, f_y \rangle + \langle f_{x_i}, f_{x_j y} \rangle = 0$$

$$(ii) \quad \langle f_{x_j x_i}, f_y \rangle + \langle f_{x_j}, f_{x_i y} \rangle = 0$$

$$(iii) \quad \langle f_{x_i y}, f_y \rangle = 0$$

and then

$$(iv) \quad \langle f_{x_i x_j y}, f_y \rangle + \langle f_{x_j x_i}, f_{yy} \rangle + \langle f_{x_j y}, f_{x_i y} \rangle + \langle f_{x_j}, f_{x_i y y} \rangle = 0 \quad \text{from (ii)}$$

$$(v) \quad \langle f_{x_i x_j y}, f_y \rangle + \langle f_{x_i y}, f_{x_j y} \rangle = 0 \quad \text{from (iii)}.$$

Equations (iv) and (v) give

$$\langle f_{x_i y y}, f_{x_j} \rangle = -\langle f_{x_i x_j}, f_{yy} \rangle,$$

so we have

$$\begin{aligned} \langle f_{x_i}, f_{x_j} \rangle_{yy} &= \langle f_{x_i y y}, f_{x_j} \rangle + 2\langle f_{x_i y}, f_{x_j y} \rangle + \langle f_{x_i}, f_{x_j y y} \rangle \\ &= -2\langle f_{x_i x_j}, f_{yy} \rangle + 2\langle f_{x_i y}, f_{x_j y} \rangle \\ &= (g_{ij})_{yy} \quad \text{by (3c).} \end{aligned}$$

On the other hand, (i) and (ii) give

$$\begin{aligned} \langle f_{x_i}, f_{x_j} \rangle_y &= -2\langle f_{x_i x_j}, f_y \rangle \\ &= (g_{ij})_y \quad \text{on } H_k, \quad \text{by (2a).} \end{aligned}$$

It follows that $\langle f_{x_i}, f_{x_j} \rangle_y = (g_{ij})_y$ everywhere. Since we have $\langle f_{x_i}, f_{x_j} \rangle = g_{ij}$ on H_k , we conclude that $\langle f_{x_i}, f_{x_j} \rangle = g_{ij}$ everywhere, as desired.

Step 2. Having established this, we now claim that there is an analytic function χ on H_k such that

$$(2') \quad \begin{aligned} \langle \chi, f_{x_i x_j} \rangle &= -\frac{1}{2}(g_{ij})_y \\ \langle \chi, f_{x_i} \rangle &= 0 \\ \langle \chi, \chi \rangle &= 1 \end{aligned} \quad \text{on } H_k,$$

χ is linearly independent of $f_{x_i}, f_{x_i x_j}$.

The reason for this is the following. At 0, we have $(g_{ij})_y = 0$ (Proposition II.4-1). So $\chi(0)$ is just a unit vector in \mathbb{R}^{s_n} which is perpendicular to all $f_{x_i}(0)$ and $f_{x_i x_j}(0)$ [such a vector exists, since $k + s_k < s_n$]. In general, we first pick a linear combination χ_1 of the (linearly independent) vectors $f_{x_i}, f_{x_i x_j}$ so that the first two conditions in (2') hold for χ_1 . Near 0, this makes χ_1 a vector of small norm. Then we add on an appropriate vector orthogonal to the f_{x_i} and $f_{x_i x_j}$ so that the norm becomes 1. There is no problem arranging for χ to be analytic.

Consider the following system of equations for functions $f, q: H_{k+1} \rightarrow \mathbb{R}^{s_n}$:

$$(*) \quad \begin{cases} f_y = q \\ \langle q_y, f_{x_i} \rangle = 0 & i = 1, \dots, k \\ \langle q_y, q \rangle = 0 \\ \langle q_y, f_{x_i x_j} \rangle = -\frac{1}{2}(g_{ij})_{yy} + \langle q_{x_i}, q_{x_j} \rangle & i, j = 1, \dots, k, \end{cases}$$

with the initial conditions

$$(*_0) \quad \begin{cases} f(x, 0) = f_k(x) \\ q(x, 0) = \chi(x) \end{cases} \quad \text{on } H_k.$$

If we have a solution (f, q) , then f will be a solution of (3) such that $\chi(x) = f_y(x, 0)$ satisfies (2) on H_k , so f will be an analytic isometric imbedding extending f_k in a neighborhood of 0. Now (*) is rather like the equations considered in the Cauchy-Kowalewski theorem, expressing the partials of the $2s_n$ functions $f^1, \dots, f^{s_n}, q^{s_1}, \dots, q^{s_n}$ with respect to y in terms of their partials with respect to x_1, \dots, x_k . However, we have more unknowns than equations (except for $k = n - 1$), and the q_y are not explicitly solved for. Such a problem is handled as follows.

Step 3. Write the last three sets of equations of (*) as a matrix equation

$$\begin{pmatrix} f_{x_i} \\ q \\ f_{x_i x_j} \end{pmatrix} \cdot \begin{pmatrix} q^1_y \\ \vdots \\ q^{s_n}_y \end{pmatrix} = \begin{pmatrix} 0 \\ \vdots \\ 0 \\ \vdots \\ -\frac{1}{2}(g_{ij})_{yy} + \langle q_{x_i}, q_{x_j} \rangle \\ \vdots \end{pmatrix},$$

\uparrow
 $(k+1+s_k) \times s_n$
matrix

\uparrow
 $s_n \times 1$
matrix

\uparrow
 $(k+1+s_k) \times 1$
matrix

or for short as

$$B(f_{x_i}, q, f_{x_i x_j}) \cdot q_y = g.$$

On H_k , the rows of $B(f_{x_i}, q, f_{x_i x_j})$ are linearly independent, because f_k is non-degenerate, and by the choice (2') of χ . So this matrix has a right inverse. Moreover, we can pick this inverse analytically—that is, for any $r \leq s$ there is an analytic map $B \mapsto \tilde{B}$ from the $r \times s$ matrices of rank r to the $s \times r$ matrices such that

$$B \cdot \tilde{B} = r \times r \text{ identity matrix.}$$

[One specific way to define \tilde{B} is as follows. Write B as a collection of row vectors, $B = \begin{pmatrix} v_1 \\ \vdots \\ v_4 \end{pmatrix}$ for $v_i \in \mathbb{R}^s$. There is a unique decomposition $v_i = w_i + z_i$, where

$$w_i \in \text{subspace } W_i \subset \mathbb{R}^s \text{ spanned by } v_1, \dots, \hat{v}_i, \dots, v_r, \quad z_i \perp W_i;$$

clearly $z_i \neq 0$. Then

$$\langle v_i, z_j \rangle = \begin{cases} 0 & i \neq j \\ \langle z_i, z_i \rangle & i = j, \end{cases}$$

so we can choose \tilde{B} to be the matrix whose *columns* are $z_i / \langle z_i, z_i \rangle$.]

Now consider the system of equations

$$(**) \quad \begin{cases} f_y = q \\ q_y = \tilde{B}(f_{x_i}, q, f_{x_i x_j}) \cdot g, \end{cases}$$

with the initial conditions (*₀). This equation makes sense in a neighborhood

of H_k , since the rows of $B(f_{x_i}, q, f_{x_i x_j})$ are linearly independent there. Any solution of $(**)$ will be a solution of $(*)$, since

$$q_y = \tilde{B}(f_{x_i}, q, f_{x_i x_j}) \cdot g \implies B(f_{x_i}, q, f_{x_i x_j}) \cdot q_y = g.$$

But $(**)$ is a set of equations to which the Cauchy-Kowalewski theorem applies [more precisely, it can be reduced to such a set by the method of section 4 of Chapter 10]. Thus we have established the existence of the extension f .

Step 4. We still have to arrange for f to be non-degenerate when $k+1 < n$. We claim first that we can choose χ on H_k so that χ satisfies $(2')$, and also so that the vectors $\chi, \chi_{x_i}, f_{x_i}, f_{x_i x_j}$ are linearly independent at 0. To do this we again first choose χ_1 to be a linear combination of the $f_{x_i}, f_{x_i x_j}$ which satisfies the first two conditions of $(2')$; near 0 we have $|\chi_1| < 1$. We next choose $\alpha: H_k \rightarrow \mathbb{R}^{s_n}$ to be an analytic map with α perpendicular to $f_{x_i}, f_{x_i x_j}$ and $|\alpha|$ small. Then there is a constant λ_0 with $|\chi_1 + \lambda_0 \alpha| = 1$ at 0. We can assume, by renumbering, that the vectors of the set

$$A = \{\alpha, (\chi + \lambda_0 \alpha)_{x_1}, \dots, (\chi + \lambda_0 \alpha)_{x_h}, f_{x_i}, f_{x_i x_j}\}$$

are linearly independent at 0, and that $h \leq k$ is the largest integer with this property ($h = 0$ is a possibility, i.e., there may be no vectors $(\chi + \lambda_0 \alpha)_{x_i}$ in our set). If $h = k$ we are done. Otherwise, pick non-zero analytic functions $\beta_{h+1}, \dots, \beta_k$ which are orthogonal to the vectors of A , and also mutually orthogonal. Then determine the analytic function λ so that

$$|\chi(x)| = \left| \chi_1(x) + \lambda(x) \cdot \left(\alpha(x) + \sum_{i=h+1}^k \beta_i(x) \cdot x_i \right) \right| = 1.$$

Thus $\lambda_0 = \lambda(0)$. Suppose some linear combination of $\chi, \chi_{x_i}, f_{x_i}, f_{x_i x_j}$ vanishes at 0. I.e., suppose that at 0 we have

$$\begin{aligned} 0 = & a(\chi_1 + \lambda \alpha) + \sum_{i=1}^h a_i((\chi_1)_{x_i} + \lambda \alpha_{x_i} + \lambda_{x_i} \alpha) \\ & + \sum_{i=h+1}^k a_i((\chi_1)_{x_i} + \lambda \alpha_{x_i} + \lambda_{x_i} \alpha + \lambda \beta_i) \\ & + \sum_{i=1}^k b_i f_{x_i} + \sum_{i,j=1}^k b_{ij} f_{x_i x_j}. \end{aligned}$$

Take the inner product with some $\beta_i(0)$ ($i = h+1, \dots, k$). The β_i are mutually orthogonal, and β_i is perpendicular to all vectors of A ; moreover, each

$(\chi_1)_{x_i} + \lambda \alpha_{x_i}$ ($i = h+1, \dots, k$) is a linear combination of elements of A , by the maximality property of A . So we end up with

$$\lambda(0)a_i|\beta_i(0)|^2 = 0 \implies a_i = 0.$$

Then we also have $a = a_i = b_i = b_{ij} = 0$, since the vectors of A are linearly independent. Thus χ has all the required properties.

Now in a neighborhood of the $s_k + 2k + 1$ linearly independent vectors $\chi(0), \chi_{x_i}(0), f_{x_i}(0), f_{x_i x_j}(0)$ we can choose an analytic map $(v, v_i, w_i, w_{ij}) \mapsto h(v, v_i, w_i, w_{ij}) \neq 0$ such that

$$h(v, v_i, w_i, w_{ij}) \text{ is perpendicular to } v, v_i, w_i, w_{ij}.$$

Consider the equations

$$(**) \quad \begin{cases} f_y = q \\ q_y = \tilde{B}(f_{x_i}, q, f_{x_i x_j}) \cdot g + h(q, q_{x_i}, f_{x_i}, f_{x_i x_j}), \end{cases}$$

with the initial conditions $(*)_0$. A solution will again be a solution of $(*)$, since our choice of h gives

$$B(f_{x_i}, q, f_{x_i x_j}) \cdot h(q, q_{x_i}, f_{x_i}, f_{x_i x_j}) = 0.$$

The vectors $f_y, f_{yx_i}, f_{x_i}, f_{x_i x_j}$ are linearly independent near 0, by our choice of χ . Then $f_{yy} = q_y$ will be independent of $f_y, f_{yx_i}, f_{x_i}, f_{x_i x_j}$, since $h(f_y, f_{yx_i}, f_{x_i}, f_{x_i x_j})$ is linearly independent of all these vectors, while our explicit construction of \tilde{B} makes its columns span the same space as the rows of B , which implies that $\tilde{B}(f_{x_i}, q, f_{x_i x_j}) \cdot g$ is a linear combination of the $q, f_{x_i}, f_{x_i x_j}$. So f is non-degenerate. ♦

This proof can naturally be applied to the case $n = 2$, and then there is only the step from $k = 1$ to $k + 1 = 2$. In this case, the matrix $B(f_x, q, f_{xx})$ is a 3×3 invertible matrix, so we just consider the equations

$$\begin{aligned} f_y &= q \\ q_y &= B(f_x, q, f_{xx})^{-1} \cdot g. \end{aligned}$$

One can check that this is a hyperbolic system when $K < 0$, so that Theorem 10-12 can be applied, with the initial choice $f_1: (x\text{-axis}) \rightarrow \mathbb{R}^3$ being C^∞ rather than analytic; thus we can obtain the same results as we got by looking at the Darboux equation previously. Perhaps one could even try to analyze higher dimensional cases similarly, when the given metric has all sectional curvatures < 0 . There is not much interest in doing this, however, for although analyticity

was required to obtain the “best possible” local result of Theorem 9, there are global results where it is not needed. These results are essentially theorems in analysis, rather than geometry [with certain significant exceptions], and generally require rather involved techniques, some of which were created precisely for this problem. So we will merely indicate what these results are, and our discussion will be particularly brief since there are now several research reports which cover the field quite well.

One class of global results gives very strong information about the special case of surfaces in \mathbb{R}^3 . The first such question was raised by Hermann Weyl, who asked whether every metric $\langle \cdot, \cdot \rangle$ on S^2 with $K > 0$ comes from an isometric immersion in \mathbb{R}^3 (necessarily an imbedding as a convex surface, by Hadamard's Theorem). Although Weyl indicated an approach to this problem, the first affirmative solution, for analytic metrics, was given by H. Lewy [2]. A proof for C^k metrics, $k \geq 4$, was given by Nirenberg [1], and the cases $k = 2, 3$ were later handled by Heinz [1]. Already in 1942, A. D. Alexandrov had considered Weyl's problem from a completely different, totally geometric approach, involving polyhedral approximations to the surface. He was able to solve Weyl's problem for C^2 metrics, although his result did not indicate how differentiable the resulting surface would be when the metric was more differentiable. But this was established by later research, especially that of Pogorelov. At the same time, this pioneering work of Alexandrov led him to investigate arbitrary convex surfaces (which need not be smooth at all); although such surfaces may not have Riemannian metrics, we can still define an isometry between two such surfaces to be a homeomorphism preserving lengths of curves, and there are suitable generalizations of other differential geometric concepts like curvature (which may exist only almost everywhere). In consequence, there has developed an entirely disjoint school of differential geometry, whose practitioners are almost exclusively Russian mathematicians, which proves certain results in far greater generality than classical differential geometry, and has sometimes proved results from this field which are still inaccessible by the classical methods. Some examples of this will be mentioned in the next chapter, and the Bibliography gives further references to the Russian school.

In contrast to Weyl's problem, which arises by considering the metric $\langle \cdot, \cdot \rangle$ induced on S^2 by some imbedding of S^2 as a convex set in \mathbb{R}^3 , we now consider a strictly convex surface $M \subset \mathbb{R}^3$ and define a function $k > 0$ on S^2 by

$$K(p) = k(v(p)),$$

where $K > 0$ is the curvature of M , and the diffeomorphism $v: M \rightarrow S^2$ is

the normal map. This function k always satisfies certain integral equalities. To derive them, we note that we have

$$0 = \int_M v^i dA = \int_M \left\langle v, \frac{\partial}{\partial x^i} \right\rangle dA;$$

this follows from the Divergence Theorem (Problem I.9-13 or Theorem 7-57), applied to the region D bounded by M . Consequently, if da is the volume element of S^2 , and $x^i/k(x)$ denotes the function $x \mapsto x^i/k(x)$ on S^2 , then

$$\begin{aligned} (*) \quad \int_{S^2} \frac{1}{k(x)} \cdot x^i da &= \int_M v^* \left(\frac{1}{k(x)} \cdot x^i da \right) \\ &= \int_M \frac{1}{k \circ v} \cdot v^i \cdot v^*(da) \\ &= \int_M \frac{1}{K} \cdot v^i \cdot K dA = \int_M v^i dA \\ &= 0. \end{aligned}$$

“Minkowski’s problem” is to show that any function $k > 0$ on S^2 which satisfies the conditions (*) is $K \circ v^{-1}$ for some convex $M \subset \mathbb{R}^3$. This problem was solved by Lewy [3] in the analytic case, and by Nirenberg [1] in the C^2 case. It should also be mentioned that generalizations of Minkowski’s problem have been given in higher dimensions, in the style of the Russian school, by A. D. Alexandrov [3] and Fenchel and Jessen [1], but for the higher dimensional cases little is known about the differentiability of the hypersurfaces obtained.

Less delicate, but much more general, results are now available for the problem of isometrically imbedding arbitrary Riemannian manifolds in some Euclidean space. The first results along this line were by Nash [1], supplemented by Kuiper [1]. For a compact n -dimensional Riemannian manifold M , their results show that if M has any imbedding in \mathbb{R}^q , with $q \geq n+1$, then it also has a C^1 isometric imbedding. Thus compact orientable surfaces always have a C^1 isometric imbedding in \mathbb{R}^3 ; in particular, even the flat torus can be C^1 isometrically imbedded in \mathbb{R}^3 ! The most important isometric imbedding theorems stem from a second paper of Nash [2], where he proved that every C^∞ Riemannian manifold can be C^∞ isometrically imbedded in some Euclidean space. We will not give the dimensions of the Euclidean spaces involved; for this the reader may consult Gromov and Rokhlin [1], which gives a very complete discussion of the results known up to 1970. We merely mention that almost nothing is known about the lowest dimensional Euclidean space in which the imbedding is possible.

ADDENDUM

THE EMBEDDING PROBLEM VIA DIFFERENTIAL SYSTEMS

Although the general line of argument for the proof of Theorem 9 was proposed by Janet, it was Burstin who gave the first rigorous proof. The result is often known as the Cartan-Janet theorem because É. Cartan gave another (completely different) rigorous proof, using his theory of differential systems (Chapter 10, Addendum 1). We will give this proof here; so we assume that we have an analytic Riemannian metric in a neighborhood of $0 \in \mathbb{R}^n$, and we seek a local isometric imbedding into \mathbb{R}^{s_n} , $s_n = n(n+1)/2$.

Let $O(T\mathbb{R}^{s_n})$ be the bundle of orthonormal frames of \mathbb{R}^{s_n} , on which we have the dual forms ϕ^α and connection forms ψ_β^α ($1 \leq \alpha, \beta \leq s_n$); for simplicity we do not use bold-face letters for these forms on $O(T\mathbb{R}^{s_n})$. The forms $\phi^\alpha, \psi_\beta^\alpha$ give a basis for the dual space of the tangent space $O(T\mathbb{R}^{s_n})_u$ for any $u \in O(T\mathbb{R}^{s_n})$. Also let Z_1, \dots, Z_n be some fixed orthonormal moving frame on \mathbb{R}^n , with dual forms θ^i , connection forms ω_j^i , and curvature forms Ω_j^i . Suppose that $f: U \rightarrow \mathbb{R}^{s_n}$ is an isometry, for some neighborhood U of 0 in \mathbb{R}^n . Let $s = (Y_1, \dots, Y_n, Y_{n+1}, \dots, Y_{s_n})$ be any orthonormal moving frame on $f(U)$ with $Y_i = f_* Z_i$ for $i = 1, \dots, n$; then $s^* \phi^\alpha$ and $s^* \psi_\beta^\alpha$ are its dual forms and connection forms. Since f is an isometry, we clearly have

$$\begin{aligned}\theta^i &= f^*(s^* \phi^i) = (s \circ f)^* \phi^i & i &= 1, \dots, n \\ 0 &= f^*(s^* \phi^r) = (s \circ f)^* \phi^r & r &= n+1, \dots, s_n.\end{aligned}$$

Conversely, if $F: U \rightarrow O(T\mathbb{R}^{s_n})$ is a map which can be written as $F = s \circ f$, and

$$\begin{aligned}\theta^i &= F^* \phi^i & i &= 1, \dots, n \\ 0 &= F^* \phi^r & r &= n+1, \dots, s_n,\end{aligned}$$

then f is an isometry. We will look for F , and hence f , by looking for its graph in $\mathbb{R}^n \times O(T\mathbb{R}^{s_n})$. We have two projections

$$\begin{array}{ccc}\mathbb{R}^n \times O(T\mathbb{R}^{s_n}) & \xrightarrow{\pi_2} & O(T\mathbb{R}^{s_n}) \\ \downarrow \pi_1 & & \\ \mathbb{R}^n & & \end{array}$$

and for simplicity we will denote

$$\begin{aligned} \pi_1^* \theta^i & \text{ by } \theta^i, & \pi_1^* \omega_j^i & \text{ by } \omega_j^i, & \pi_1^* \Omega_j^i & \text{ by } \Omega_j^i, \\ \pi_2^* \phi^\alpha & \text{ by } \phi^\alpha, & \pi_2^* \psi_\beta^\alpha & \text{ by } \psi_\beta^\alpha. \end{aligned}$$

We easily see that our problem is solved if there is an n -dimensional manifold $\Gamma \subset \mathbb{R}^n \times O(T\mathbb{R}^{s_n})$ through some point $(0, u)$, such that $\pi_{1*}: \Gamma_{(0, u)} \rightarrow \mathbb{R}^n_0$ is one-one, and such that

$$\begin{aligned} \phi^i - \theta^i &= 0 & \text{ on } \Gamma & & i = 1, \dots, n \\ \phi^r &= 0 & \text{ on } \Gamma & & r = n+1, \dots, s_n. \end{aligned}$$

We want to find Γ as an integral manifold for an appropriate differential system \mathcal{L} . So, first of all, we want \mathcal{L} to contain the $\phi^i - \theta^i$ and the ϕ^r . Now

$$\begin{aligned} d(\phi^i - \theta^i) &= - \sum_{\alpha=1}^{s_n} \psi_\alpha^i \wedge \phi^\alpha + \sum_{j=1}^n \omega_j^i \wedge \theta^j \\ &= - \sum_{j=1}^n (\psi_j^i - \omega_j^i) \wedge \theta^j - \sum_{j=1}^n \psi_j^i \wedge (\phi^j - \theta^j) - \sum_{r=n+1}^{s_n} \psi_r^i \wedge \phi^r, \end{aligned}$$

and

$$\begin{aligned} d\phi^r &= - \sum_{\alpha=1}^{s_n} \psi_\alpha^r \wedge \phi^\alpha \\ &= - \sum_{j=1}^n \psi_j^r \wedge \theta^j - \sum_{j=1}^n \psi_j^r \wedge (\phi^j - \theta^j) - \sum_{t=n+1}^{s_n} \psi_t^r \wedge \theta^t, \end{aligned}$$

so in order to have $d\mathcal{L} \subset \mathcal{L}$ we also want the $\psi_j^i - \omega_j^i$ and the $\sum_j \psi_j^r \wedge \theta^j$ to be in \mathcal{L} . Similarly, since

$$\begin{aligned} d(\psi_j^i - \omega_j^i) &= - \sum_{\alpha=1}^{s_n} \psi_\alpha^i \wedge \psi_j^\alpha - \Omega_j^i + \sum_{h=1}^n \omega_h^i \wedge \omega_j^h \\ &= - \sum_{h=1}^n \psi_h^i \wedge (\psi_j^h - \omega_j^h) - \sum_{h=1}^n (\psi_h^i - \omega_h^i) \wedge \omega_j^h \\ &\quad - \sum_{r=n+1}^{s_n} \psi_r^i \wedge \psi_j^r - \Omega_j^i, \end{aligned}$$

we also want the $\sum_r \psi_r^i \wedge \psi_r^j - \Omega_j^i$ to be in \mathcal{L} . Moreover, we easily see that if \mathcal{L} is generated by

$$\begin{aligned}
 (a) \quad & \phi^i - \theta^i & i = 1, \dots, n \\
 (b) \quad & \phi^r & r = n+1, \dots, s_n \\
 (c) \quad & \psi_j^i - \omega_j^i & i, j = 1, \dots, n \\
 (d) \quad & \sum_{j=1}^n \psi_j^r \wedge \theta^j & r = n+1, \dots, s_n \\
 (e) \quad & \sum_{r=n+1}^{s_n} \psi_r^i \wedge \psi_r^j - \Omega_j^i & i, j = 1, \dots, n,
 \end{aligned}$$

then we have $d\mathcal{L} \subset \mathcal{L}$. The Cartan-Kähler Theorem (Theorem 10-15) tells us that the desired n -dimensional manifold $\Gamma \subset \mathbb{R}^n \times O(T\mathbb{R}^{s_n})$ exists if for some $u \in O(T\mathbb{R}^{s_n})$ there is an n -dimensional integral element $W \subset O(T\mathbb{R}^{s_n})_{(0,u)}$ of \mathcal{L} which contains a regular $(n-1)$ -dimensional integral element of \mathcal{L} , and for which $\pi_{1*}: W \rightarrow \mathbb{R}^n_0$ is one-one. We assume $n \geq 2$, since the case $n = 1$ is trivial.

We claim, first of all, that every point of $\mathbb{R}^n \times O(T\mathbb{R}^{s_n})$ is a regular 0-dimensional element of \mathcal{L} . To prove this we have to consider each $\mathcal{E}_1((x, u))$ for $(x, u) \in \mathbb{R}^n \times O(T\mathbb{R}^{s_n})$. By definition, $\mathcal{E}_1((x, u))$ is the set of all vectors (X, Y) [with $X \in \mathbb{R}^n_x$ and $Y \in O(T\mathbb{R}^{s_n})_u$] such that the forms (a)–(c) vanish on (X, Y) , that is:

$$(l) \quad \begin{cases} \phi^i(u)(Y) = \theta^i(x)(X) & i = 1, \dots, n \\ \phi^r(u)(Y) = 0 & r = n+1, \dots, s_n \\ \psi_j^i(u)(Y) = \omega_j^i(x)(X) & i, j = 1, \dots, n. \end{cases}$$

Because the $\phi^\alpha(u), \psi_\beta^\alpha(u)$ are a basis for $O(T\mathbb{R}^{s_n})_u$, the dimension of $\mathcal{E}_1((x, u))$ is always exactly the dimension of $\mathbb{R}^n \times O(T\mathbb{R}^{s_n})$ minus the number of forms (a)–(c), and thus a (non-zero) constant. So each (x, u) is a regular 0-dimensional integral element.

For any tangent vector $Y \in O(T\mathbb{R}^{s_n})_u$, it will be convenient to consider n vectors $Y^{(i)}$ in $\mathbb{R}^{s_n-n} = \mathbb{R}^{n(n-1)/2}$, defined by

$$Y^{(i)} = (\psi_i^{n+1}(u)(Y), \dots, \psi_i^{s_n}(u)(Y)).$$

Note that we can always choose $Y \in O(T\mathbb{R}^{s_n})_u$ satisfying (l) [i.e., with $(X, Y) \in \mathcal{E}_1((x, u))$] such that the $Y^{(i)}$ are any given n vectors in $\mathbb{R}^{n(n-1)/2}$.

Now at any point (x, u) , pick $(X_1, Y_1) \in \mathcal{E}_1((x, u))$ with X_1 a unit vector so that the $n - 1$ vectors

$$Y_1^{(1)}, \dots, Y_1^{(n-1)} \in \mathbb{R}^{n(n-1)/2}$$

are linearly independent [this is possible since $n(n - 1)/2 \geq n - 1$ for $n \geq 2$], and consider $\mathcal{E}_2((x, u), (X_1, Y_1))$. It is the set of all (X_2, Y_2) such that (l) holds, and such that the forms (d) and (e) vanish on the pair $(X_1, Y_1), (X_2, Y_2)$. If X_2 is a multiple of X_1 , then (l) implies that Y_2 is the same multiple of Y_1 , so we will assume that X_2 is linearly independent of X_1 . Since $(X_2, Y_2) \in \mathcal{E}_2((x, u), (X_1, Y_1))$ implies that any linear combination of (X_1, Y_1) and (X_2, Y_2) is also in $\mathcal{E}_2((x, u), (X_1, Y_1))$, in computing the dimension of this space we can restrict our attention to (X_2, Y_2) with X_1, X_2 orthonormal. Extend X_1, X_2 to an orthonormal basis X_1, \dots, X_n at u . Then (d) and (e) vanish on the pair $(X_1, Y_1), (X_2, Y_2)$ if and only if

$$(2) \quad Y_2^{(1)} = Y_1^{(2)}$$

$$(3) \quad Y_2^{(j)} \cdot Y_1^{(i)} - Y_2^{(i)} \cdot Y_1^{(j)} - \langle R(X_1, X_2)X_j, X_i \rangle = 0 \quad 1 \leq i < j \leq n,$$

where \cdot denotes the usual inner product in $\mathbb{R}^{n(n-1)/2}$. Equation (2) determines $Y_2^{(1)}$; then equation (3) for $i = 1, j = 2$ determines a hyperplane $H_2 \subset \mathbb{R}^{n(n-1)/2}$ in which $Y_2^{(2)}$ must lie; then equations (3) for $i = 1, j = 3$ and $i = 2, j = 3$ determine a plane $H_3 \subset \mathbb{R}^{n(n-1)/2}$ of codimension 2 in which $Y_2^{(3)}$ must lie; etc. [we use here the fact that $Y_1^{(1)}, \dots, Y_1^{(n-1)}$ are linearly independent]. In particular, the dimension of $\mathcal{E}_2((x, u), (X_1, Y_1))$ is the minimum possible. Thus (X_1, Y_1) generates a regular 1-dimensional integral element. Notice that $\mathcal{E}_2((x, u), (X_1, Y_1))$ does contain some (X_2, Y_2) [with X_1, X_2 orthonormal], since each H_α ($\alpha = 2, \dots, n$) has dimension

$$\frac{n(n-1)}{2} - (\alpha - 1) \geq \frac{n(n-1)}{2} - (n-1) \geq 0 \quad \text{for } n \geq 2.$$

In the case $n = 2$, we have just shown that there is some 2-dimensional integral element containing the regular 1-dimensional integral element generated by (X_1, Y_1) , which completes the proof. In the case $n \geq 3$ we claim that we can choose Y_2 so that

$$Y_1^{(1)}, \dots, Y_1^{(n-1)}, Y_2^{(2)}, \dots, Y_2^{(n-1)}$$

are linearly independent. We choose $Y_2^{(\alpha)}$ successively for $\alpha = 2, \dots, n-1$. We want $Y_2^{(\alpha)}$ to be linearly independent of the vectors in the set

$$A = \{Y_1^{(1)}, \dots, Y_1^{(n-1)}, Y_2^{(2)}, \dots, Y_2^{(\alpha-1)}\}.$$

Now $Y_2^{(\alpha)}$ must lie in the plane H_α , which is perpendicular to the vectors in the set

$$B = \{Y_1^{(1)}, \dots, Y_1^{(\alpha-1)}\}.$$

So we just need to have $\dim H_\alpha$ greater than the number of vectors in the set

$$A - B = \{Y_1^{(\alpha)}, \dots, Y_1^{(n-1)}, Y_2^{(2)}, \dots, Y_2^{(\alpha-1)}\}.$$

Thus we need

$$\dim H_\alpha = \frac{n(n-1)}{2} - (\alpha-1) > (n-\alpha) + (\alpha-2),$$

or

$$\frac{n(n-1)}{2} > (n-1) + (\alpha-2).$$

But for $\alpha \leq n-1$ we have

$$\begin{aligned} (n-1) + (\alpha-2) &\leq (n-1) + (n-3) \\ &< (n-1) + (n-2) \\ &\leq 1 + \dots + n-1 = \frac{n(n-1)}{2}. \end{aligned}$$

This proves the claim.

Now suppose that for some $k \leq n-1$ we have found $(X_1, Y_1), \dots, (X_k, Y_k)$ with X_1, \dots, X_k orthonormal such that

- (i) $(X_1, Y_1), \dots, (X_k, Y_k)$ generate a k -dimensional integral element,
- (ii) $(X_1, Y_1), \dots, (X_{k-1}, Y_{k-1})$ generate a regular $(k-1)$ -dimensional integral element,
- (iii) the $(n-1) + (n-2) + \dots + (n-k)$ vectors

$$Y_1^{(1)}, \dots, Y_1^{(n-1)}, Y_2^{(2)}, \dots, Y_2^{(n-1)}, \dots, Y_k^{(k)}, \dots, Y_k^{(n-1)}$$

are linearly independent.

[We have just done this for $k = 2$.] We claim that $(X_1, Y_1), \dots, (X_k, Y_k)$ generate a *regular* k -dimensional integral element, which can be extended to a $(k+1)$ -dimensional integral element generated by $(X_1, Y_1), \dots, (X_{k+1}, Y_{k+1})$ [with X_1, \dots, X_{k+1} orthonormal]; moreover, if $k+1 \leq n-1$, then Y_{k+1} can be picked so that $Y_{k+1}^{(k+1)}, \dots, Y_{k+1}^{(n-1)}$ are linearly independent of the vectors in (iii). Once we have proved this claim, it will clearly follow that there is

some n -dimensional integral element spanned by $(X_1, Y_1), \dots, (X_n, Y_n)$, with X_1, \dots, X_n orthonormal, such that $(X_1, Y_1), \dots, (X_{n-1}, Y_{n-1})$ span a regular $(n-1)$ -dimensional integral element. Thus the proof will be complete.

To calculate the dimension of $\mathcal{E}_{k+1}((x, u), (X_1, Y_1), \dots, (X_k, Y_k))$ we consider (X_{k+1}, Y_{k+1}) with X_1, \dots, X_{k+1} orthonormal, and again extend X_1, \dots, X_{k+1} to an orthonormal basis X_1, \dots, X_n at x . Then (d) and (e) vanish on the pairs $(X_h, Y_h), (X_{k+1}, Y_{k+1})$ ($1 \leq h \leq k$) if and only if

$$(2') \quad Y_{k+1}^{(h)} = Y_h^{(k+1)} \quad h = 1, \dots, k$$

$$(3') \quad Y_{k+1}^{(j)} \cdot Y_h^{(i)} - Y_{k+1}^{(i)} \cdot Y_h^{(j)} - \langle R(X_h, X_{k+1})X_j, X_i \rangle = 0 \quad \begin{array}{l} h = 1, \dots, k \\ 1 \leq i \leq j \leq n. \end{array}$$

Equations (2') determine $Y_{k+1}^{(h)}$ for $h \leq k$. We claim that with these values of $Y_{k+1}^{(h)}$, equation (3') holds for $i, j \leq k$. In fact, by hypothesis (i) we have

$$(a) \quad Y_h^{(i)} = Y_i^{(h)}, \quad Y_h^{(j)} = Y_j^{(h)} \quad i, j, h \leq k,$$

as well as

$$(b) \quad Y_i^{(l)} \cdot Y_j^{(\lambda)} - Y_i^{(\lambda)} \cdot Y_j^{(l)} - \langle R(X_j, X_i)X_l, X_\lambda \rangle = 0 \quad \begin{array}{l} i, j \leq k \\ \text{all } l, \lambda \leq n. \end{array}$$

Choose $l = h$ and $\lambda = k+1$ in (b), and substitute (2') and (a) into the equation. Using the identity $\langle R(X_j, X_i)X_h, X_{k+1} \rangle = \langle R(X_h, X_{k+1})X_j, X_i \rangle$, we obtain (3') for $i, j \leq k$.

Thus, we need to consider (3') only for i or $j \geq k+1$. Since we are choosing $i < j$, we have $j \geq k+1$ in either case. Moreover, we claim that for each $j \geq k+1$, and $h \leq k$, we need only consider the cases $h \leq i$. For if we have all these cases, and $i < h$, then by choosing i as our h , and h as our i , we have

$$(c) \quad Y_{k+1}^{(j)} \cdot Y_i^{(h)} - Y_{k+1}^{(h)} \cdot Y_i^{(j)} - \langle R(X_i, X_{k+1})X_j, X_h \rangle = 0.$$

Moreover, by (b) we also have

$$(d) \quad Y_h^{(k+1)} \cdot Y_i^{(j)} - Y_h^{(j)} \cdot Y_i^{(k+1)} - \langle R(X_i, X_h)X_{k+1}, X_j \rangle = 0.$$

In addition, (2') and (a) give

$$Y_h^{(k+1)} = Y_{k+1}^{(h)}, \quad Y_i^{(h)} = Y_h^{(i)}, \quad Y_i^{(k+1)} = Y_{k+1}^{(i)}.$$

So adding (c) and (d) gives

$$Y_{k+1}^{(j)} \cdot Y_h^{(i)} - Y_{k+1}^{(i)} \cdot Y_h^{(j)} - [\langle R(X_i, X_h)X_{k+1}, X_j \rangle + \langle R(X_i, X_{k+1})X_j, X_h \rangle] = 0.$$

Using the identities for the curvature tensor, we obtain finally

$$Y_{k+1}^{(j)} \cdot Y_h^{(i)} - Y_{k+1}^{(i)} \cdot Y_h^{(j)} - \langle R(X_h, X_{k+1})X_j, X_i \rangle = 0,$$

which is indeed just the required identity for i, j .

So consider now the equations

$$(3') \quad Y_{k+1}^{(j)} \cdot Y_h^{(i)} - Y_{k+1}^{(i)} \cdot Y_h^{(j)} - \langle R(X_h, X_{k+1})X_j, X_i \rangle = 0 \quad \begin{cases} h \leq k & i \geq h \\ i < j & j \geq k+1. \end{cases}$$

For $j = k+1$, there is one equation for each of the vectors

$$Y_1^{(1)}, \dots, Y_1^{(k)}, Y_2^{(2)}, \dots, Y_2^{(k)}, \dots, Y_k^{(k)},$$

which are linearly independent, by (iii). Thus $Y_{k+1}^{(k+1)}$ is restricted to lie in some plane $H_{k+1} \subset \mathbb{R}^{n(n-1)/2}$ of codimension $1 + \dots + k$. For $j = k+2$, there is then one equation for each of the linearly independent vectors

$$Y_1^{(1)}, \dots, Y_1^{(k+1)}, Y_2^{(2)}, \dots, Y_2^{(k+1)}, \dots, Y_k^{(k)}, Y_k^{(k+1)}.$$

So $Y_{k+1}^{(k+2)}$ is restricted to lie in some plane H_{k+2} of codimension $2 + \dots + (k+1)$. Etc. We see right away that

$$\dim \mathcal{E}_{k+1}((x, u), (X_1, Y_1), \dots, (X_k, Y_k))$$

is the minimum possible, so $(X_1, Y_1), \dots, (X_k, Y_k)$ do generate a regular k -dimensional integral element. Moreover, it can be extended to a $(k+1)$ -dimensional integral element, by choosing an appropriate (X_{k+1}, Y_{k+1}) [with X_1, \dots, X_{k+1} orthonormal], since each H_α ($\alpha = k+1, \dots, n$) has dimension

$$\begin{aligned} & \frac{n(n-1)}{2} - [(\alpha - k) + \dots + (\alpha - 1)] \\ &= 1 + \dots + (n-1) - [(\alpha - k) + \dots + (\alpha - 1)] \\ &\geq 0. \end{aligned}$$

We claim, finally, that if $k+1 \leq n-1$, then Y_{k+1} can be picked so that $Y_{k+1}^{(k+1)}, \dots, Y_{k+1}^{(n-1)}$ are linearly independent of the vectors in (iii). We pick $Y_{k+1}^{(\alpha)}$ successively, for $\alpha = k+1, \dots, n-1$. The vector $Y_{k+1}^{(\alpha)}$ has to be picked linearly independent of the vectors in the set

$$A = \{Y_1^{(1)}, \dots, Y_1^{(n-1)}, \dots, Y_k^{(k)}, \dots, Y_k^{(n-1)}, Y_{k+1}^{(k+1)}, \dots, Y_{k+1}^{(\alpha-1)}\},$$

with cardinality $(n-k) + \dots + (n-1) + (\alpha - k - 1)$.

Equations (3') say that $Y_{k+1}^{(\alpha)}$ must lie in a plane H_α perpendicular to the vectors of the set

$$B = \{Y_1^{(1)}, \dots, Y_1^{(\alpha-1)}, Y_2^{(2)}, \dots, Y_2^{(\alpha-1)}, \dots, Y_k^{(k)}, \dots, Y_k^{(\alpha-1)}\},$$

with cardinality r , say.

This is possible if $\dim H_\alpha$ is greater than the number of vectors in the difference set $A - B$. Since r is just the codimension of H_α , we thus need to have

$$\frac{n(n-1)}{2} - r > (n-k) + \dots + (n-1) + (\alpha - k - 1) - r.$$

But for $\alpha \leq n-1$ we have

$$\begin{aligned} (n-k) + \dots + (n-1) + (\alpha - k - 1) &\leq (n-k) + \dots + (n-1) + (n-k-2) \\ &< (n-k) + \dots + (n-1) + (n-k-1) \\ &\leq 1 + \dots + (n-1) = \frac{n(n-1)}{2}, \end{aligned}$$

as required.

PROBLEMS

1. Let $a_i \neq 0$ for $1 < i < n - 1$ with $\sum_i a_i^2 = 1$. Define an immersion

$$f: \{x \in \mathbb{R}^n : x_n < 0\} \rightarrow \mathbb{R}^{2n-1}$$

by

$$\begin{aligned} f^{2i-1}(x) &= a_i e^{x_n} \cos(x_i/a_i) \\ f^{2i}(x) &= a_i e^{x_n} \sin(x_i/a_i) & 1 \leq i \leq n-1 \\ f^{2n-1}(x) &= \int_0^{x_n} \sqrt{1 - e^{2t}} dt. \end{aligned}$$

Calculate that the induced metric has constant negative curvature.

2. Let M^n be a manifold of constant curvature K isometrically immersed in a manifold N^{2n-1} of constant curvature $K_0 > K$.

(a) Using equation (1) on page 141, generalize the argument in the second proof of Lemma 5-10 to prove that the bracket of two unit asymptotic vector fields on M is zero.

(b) Also use an argument from this proof to show that if M is complete, then its universal covering space must be \mathbb{R}^n .

(c) Conclude that we cannot have $K > 0$.

3. (a) Let $T: V \rightarrow V$ be a self-adjoint linear transformation, and let $V = V_1 \oplus \cdots \oplus V_k$ where the V_i are the mutually orthogonal eigenspaces for the distinct eigenvalues $\lambda_1, \dots, \lambda_k$. Let $P_i: V \rightarrow V_i$ be the corresponding orthogonal projections, $P_i(\sum_j a_j v_j) = a_i v_i$. Show that P_i is a polynomial in T , namely,

$$\frac{(T - \lambda_1) \cdots (T - \lambda_{i-1})(T - \lambda_{i+1}) \cdots (T - \lambda_k)}{(\lambda_i - \lambda_1) \cdots (\lambda_i - \lambda_{i-1})(\lambda_i - \lambda_{i+1}) \cdots (\lambda_i - \lambda_k)}.$$

Thus we have $T = \sum_i \lambda_i P_i$ where the P_i are polynomials in T .

(b) Let $S: V \rightarrow V$ be another self-adjoint linear transformation with $S = \sum_j \mu_j Q_j$ for polynomials Q_j in S . If S and T commute, then all P_i and Q_j commute. Let $A = \sum_{ij} a_{ij} P_i Q_j$ for distinct $a_{ij} \in \mathbb{R}$. Show that A is a self-adjoint transformation, that S and T are both polynomials in A , and that any linear transformation that commutes with S and T also commutes with A .

(c) If T_1, \dots, T_r are commuting self-adjoint operators, then there is a self-adjoint transformation A such that each T_i is a polynomial in A .

(d) Consequently, T_1, \dots, T_r can be simultaneously diagonalized.

4. (a) Let $f: M \rightarrow \mathbb{R}$, where $(M, \langle \cdot, \cdot \rangle)$ is a Riemannian manifold, and consider the symmetric covariant tensor $\nabla(df)$ of order 2, with components $f_{i;j}$ in a coordinate system. Each $\nabla(df)(p): M_p \times M_p \rightarrow \mathbb{R}$ can be regarded as a linear transformation $M_p \rightarrow M_p$, by using the inner product on M_p . So we can form $\mathcal{D}f(p) = \det(\nabla(df)(p))$. Equivalently, $\mathcal{D}f(p) = \det(\nabla(df)(p)(X_i, X_j))$, where X_1, \dots, X_n is any orthonormal basis of M_p . In a coordinate system we have

$$\mathcal{D}f = \frac{\det(f_{i;j})}{\det(g_{ij})}.$$

Show that equation (*) on page 143 can be written

$$\mathcal{D}w = K(1 - \Delta_1 w).$$

(b) Check that equations (*) and (**) are the same when $F = 0$, and conclude that they are always the same.

CHAPTER 12

RIGIDITY

In Chapter 7 we proved a result (Theorem 7-47) which is but a special case of the following more general

1. THEOREM. Let M and \bar{M} be immersed hypersurfaces in \mathbb{R}^{n+1} , and let $\phi: M \rightarrow \bar{M}$ be an isometry. Suppose that $d\nu: M_p \rightarrow M_p$ has rank ≥ 3 . Then $(\phi^*\bar{\Pi})(p) = \pm\Pi(p)$. [This equation makes sense even though ν and $\bar{\nu}$ may be defined only locally, and then only up to sign.]

Consequently, if M and \bar{M} are connected (not necessarily complete) hypersurfaces and $d\nu: M_p \rightarrow M_p$ has rank ≥ 3 for all $p \in M$, then ϕ is the restriction of a Euclidean motion.

PROOF. To deduce the second part of the theorem from the first part, we recall (pg. IV.63) that there is an inner product preserving bundle isomorphism $\tilde{\phi}: \text{Nor } M \rightarrow \text{Nor } \bar{M}$ covering ϕ . The first part of the theorem shows that if $p \in M$, then

$$\begin{array}{lll} \text{either} & \bar{s}(\phi_*X, \phi_*Y) = \tilde{\phi}(s(X, Y)) & \text{for all } X, Y \in M_p \\ \text{or} & \bar{s}(\phi_*X, \phi_*Y) = -\tilde{\phi}(s(X, Y)) & \text{for all } X, Y \in M_p. \end{array}$$

Moreover, only one alternative can hold at each p , since $d\nu: M_p \rightarrow M_p$ is non-singular. It follows that one of the alternatives holds for all $p \in M$. Then Theorem 7-21 shows that f is the restriction of a Euclidean motion.

To prove the first part, let $X_1, \dots, X_n \in M_p$ be an orthonormal basis, and define the $n \times n$ symmetric matrix S by $S_{ij} = \Pi(X_i, X_j)$. Similarly, let $\bar{X}_i = \phi_*X_i \in \bar{M}_{f(p)}$ and define the symmetric $n \times n$ matrix \bar{S} by $\bar{S}_{ij} = \bar{\Pi}(\bar{X}_i, \bar{X}_j)$. Gauss' equation shows that

$$\begin{aligned} S_{i_1j_1}S_{i_2j_2} - S_{i_1j_2}S_{i_2j_1} &= \langle R(X_{i_1}, X_{i_2})X_{j_2}, X_{j_1} \rangle \\ &= \langle \bar{R}(\bar{X}_{i_1}, \bar{X}_{i_2})\bar{X}_{j_2}, \bar{X}_{j_1} \rangle, & \text{since } \phi \text{ is an isometry} \\ &= \bar{S}_{i_1j_1}\bar{S}_{i_2j_2} - \bar{S}_{i_1j_2}\bar{S}_{i_2j_1}. \end{aligned}$$

We now use an algebraic

2. LEMMA. Let S and \bar{S} be symmetric $n \times n$ matrices, with $\text{rank } S \geq 3$. Suppose that the determinant of every 2×2 submatrix of S equals the determinant of the corresponding 2×2 submatrix of \bar{S} . Then $\bar{S} = \pm S$.

PROOF. To isolate the main idea of the proof, we first consider

Case 1. The matrices S and \bar{S} are non-singular. (Then the hypothesis on the rank just means that $n \geq 3$.) Let $T, \bar{T}: \mathbb{R}^n \rightarrow \mathbb{R}^n$ be the non-singular linear transformations with matrices S, \bar{S} . Then $T^*, \bar{T}^*: \mathbb{R}^{n*} \rightarrow \mathbb{R}^{n*}$ are also non-singular. We can also consider the linear transformations

$$T^*, \bar{T}^*: \Omega^2(\mathbb{R}^n) \rightarrow \Omega^2(\mathbb{R}^n).$$

If $\phi_1, \dots, \phi_n \in \mathbb{R}^{n*}$ is the dual basis to the standard basis of \mathbb{R}^n , then

$$\begin{aligned} T^*(\phi_{i_1} \wedge \phi_{i_2}) &= T^*\phi_{i_1} \wedge T^*\phi_{i_2} \\ &= \sum_{j_1} S_{i_1 j_1} \phi_{j_1} \wedge \sum_{j_2} S_{i_2 j_2} \phi_{j_2} \\ &= \sum_{j_1 < j_2} (S_{i_1 j_1} S_{i_2 j_2} - S_{i_1 j_2} S_{i_2 j_1}) \cdot \phi_{j_1} \wedge \phi_{j_2}, \end{aligned}$$

and similarly for \bar{T}^* . Thus we see that the hypotheses on the determinants of S and \bar{S} is equivalent to the assertion that

$$(1) \quad T^* = \bar{T}^*: \Omega^2(\mathbb{R}^n) \rightarrow \Omega^2(\mathbb{R}^n).$$

Now given any $\phi \in \mathbb{R}^{n*}$, we claim that $T^*\phi$ and $\bar{T}^*\phi$ must be linearly dependent. For otherwise we could choose $\psi \in \mathbb{R}^{n*}$ with $T^*\phi, \bar{T}^*\phi, T^*\psi$ linearly independent. Then we would have

$$\begin{aligned} 0 \neq T^*\phi \wedge T^*\psi \wedge \bar{T}^*\phi &= T^*(\phi \wedge \psi) \wedge \bar{T}^*\phi \\ &= \bar{T}^*(\phi \wedge \psi) \wedge \bar{T}^*\phi \quad \text{by (1)} \\ &= \bar{T}^*\phi \wedge \bar{T}^*\psi \wedge \bar{T}^*\phi \\ &= 0, \end{aligned}$$

a contradiction. Thus $\bar{T}^*\phi = c \cdot T^*\phi$ for some $c \in \mathbb{R}$. If we choose linearly independent $\phi_1, \phi_2 \in \mathbb{R}^{n*}$, and apply this result to $\phi_1, \phi_2, \phi_1 + \phi_2$, we find that there are constants c_1, c_2, c with

$$\begin{aligned} \bar{T}^*\phi_1 &= c_1 \cdot T^*\phi_1, & \bar{T}^*\phi_2 &= c_2 \cdot T^*\phi_2 \\ \bar{T}^*\phi_1 + \bar{T}^*\phi_2 &= c \cdot (T^*\phi_1 + T^*\phi_2). \end{aligned}$$

It follows that $c_1 = c_2$. So $\bar{T}^* = c \cdot T^*$ for some $c \in \mathbb{R}$. From (1) we see that $c = \pm 1$.

Case 2. General Case. Since S is symmetric, the map $T: \mathbb{R}^n \rightarrow \mathbb{R}^n$ is self-adjoint with respect to the usual metric on \mathbb{R}^n ; that is, $\langle Tv, w \rangle = \langle v, Tw \rangle$ for $v, w \in \mathbb{R}^n$. Similarly, if we give \mathbb{R}^{n*} the inner product with $\langle \phi_i, \phi_j \rangle = \delta_{ij}$, then

$$(2) \quad \langle T^*\phi, \psi \rangle = \langle \phi, T^*\psi \rangle \quad \text{for } \phi, \psi \in \mathbb{R}^{n*}.$$

Let $(\ker T^*)^\perp \subset \mathbb{R}^{n*}$ be the orthogonal complement of $\ker T^* \subset \mathbb{R}^{n*}$ with respect to this inner product. We easily see from (2) that T^* takes $(\ker T^*)^\perp$ into itself and that

$$(3) \quad T^*: (\ker T^*)^\perp \rightarrow (\ker T^*)^\perp \quad \text{is one-one.}$$

We now claim:

$$(4) \quad \ker T^* = \{\phi : T^*\phi \wedge T^*\psi = 0 \text{ for all } \psi \in \mathbb{R}^{n*}\} = W, \quad \text{say.}$$

It is clear that $\ker T^* \subset W$. Conversely, given $\phi \in W$, write

$$\phi = \phi_1 + \phi_2 \quad \text{with} \quad \phi_1 \in \ker T^* \subset W, \quad \phi_2 \in (\ker T^*)^\perp.$$

Then

$$(5) \quad \phi_2 \in (\ker T^*)^\perp \cap W.$$

We want to show that $\phi_2 = 0$. Note that

$$\dim(\ker T^*)^\perp = \text{rank } T^* = \text{rank } S \geq 3,$$

so if $\phi_2 \neq 0$, then there is $\psi \in (\ker T^*)^\perp$ with ϕ_2 and ψ linearly independent. By (3), this means that $T^*\phi_2$ and $T^*\psi$ are linearly independent, so

$$0 \neq T^*\phi_2 \wedge T^*\psi,$$

contradicting the fact that $\phi_2 \in W$ [by (5)]. Thus ϕ_2 must be 0, and we have demonstrated (4).

Notice that in proving (4) we really used only the fact that $\text{rank } S \geq 2$. Now we also have $\text{rank } \bar{S} \geq 2$ (otherwise every 2×2 submatrix of \bar{S} would have determinant 0). So we also have

$$(4) \quad \ker \bar{T}^* = \{\phi : \bar{T}^*\phi \wedge \bar{T}^*\psi = 0 \text{ for all } \psi \in \mathbb{R}^{n*}\}.$$

Then equation (1) shows that $\ker T^* = \ker \bar{T}^*$. Now we can apply Case 1 to

$$T^*, \bar{T}^*: (\ker T^*)^\perp \rightarrow (\ker T^*)^\perp,$$

for these maps are one-one by (3) and the corresponding (3), and moreover $\dim(\ker T^*)^\perp = \text{rank } T^* = \text{rank } S \geq 3$. ♦

The rank of $d\nu: M_p \rightarrow M_p$ is called the **type number** $t(p)$ of M at p ; it is the number of non-zero principal curvatures at p . The hypothesis that $t(p) \geq 3$ says, roughly speaking, that M curves in at least 3 different directions at p . The hypersurfaces with $t(p) = 0$ or 1 for all p are precisely the flat hypersurfaces, with curvature tensor $R = 0$, while the hypersurfaces with $t(p) = 2$ for all p may be regarded as a sort of generalization of this class. They have been classified into three different types by É. Cartan [1], but the classification suffers the same defect as the classical classification of flat surfaces, for there is no discussion of the manner in which hypersurfaces of different types can be joined together. We will have a little more to say about this later on.

Theorem 1 is often expressed by saying that a hypersurface in \mathbb{R}^{n+1} which bends enough is “rigid”. The first precise proof was by Killing [1], although the result had been stated by Beez [1], who found it so astounding that he could barely cease discussing it, and practically regarded it as a proof that space can’t be 4-dimensional. While we might not be willing to go quite so far as that, it is nevertheless true that because of this result most of the interest in rigidity phenomena has centered on the case of surfaces in \mathbb{R}^3 , where intuition tells us that a small piece of surface is not rigid, and at the same time suggests that compact surfaces should be rigid. Actually, there are several different senses in which a surface can be rigid. Books written in English often consider only one possible sense, or tend to be rather sloppy about distinguishing the various possibilities. I therefore propose to introduce some terminology which, although it may not be especially appealing aesthetically, and suffers the disadvantage of not being standard, at least has the virtue of being unambiguous.

Consider a C^∞ imbedding $f: M \rightarrow \mathbb{R}^3$. The strongest sense in which $f(M)$ can be “bent” corresponds to the ordinary conception of the word, whereby $f(M)$ passes continuously from one shape to another, without being stretched. To express this idea precisely, we define a **bending** of the imbedding $f: M \rightarrow \mathbb{R}^3$ to be a C^∞ map $\alpha: [0, 1] \times M \rightarrow \mathbb{R}^3$ such that

- (a) each map $\bar{\alpha}(t): M \rightarrow \mathbb{R}^3$, given by $p \mapsto \alpha(t, p)$, is an imbedding,
- (b) $\bar{\alpha}(0) = f$,
- (c) $\bar{\alpha}(t)^*(\langle \cdot, \cdot \rangle) = \bar{\alpha}(0)^*(\langle \cdot, \cdot \rangle)$ for all $t \in [0, 1]$.

Thus α is a “variation” of f , in the terminology of Chapter 9. To be a little more precise, α should be called a *bending through imbeddings*, and we can also define a bending through immersions. The bending $\alpha: [0, 1] \times M \rightarrow \mathbb{R}^3$ is called **trivial** if each $\bar{\alpha}(t)$ is $A_t \circ f$ for some Euclidean motion A_t ; it is called **non-trivial** if at least one $\bar{\alpha}(t)$ is not of this form. We say that the imbedding $f: M \rightarrow \mathbb{R}^3$ is **bendable** if there is a non-trivial bending of f ; otherwise it is called **unbendable**. To be

precise, we must speak of bendability and unbendability through imbeddings or through immersions. We can also define when an immersion $f: M \rightarrow \mathbb{R}^3$ is bendable or unbendable; in this case, of course, only bendings through immersions can be relevant. (It is also possible to consider C^l bendings of C^k imbeddings and immersions, for $1 \leq l \leq k \leq \omega$; but we shall hardly ever stray from the case $k = l = \infty$.) Finally, a submanifold $M \subset \mathbb{R}^3$ is called bendable or unbendable (through imbeddings or immersions) according as whether the inclusion map $i: M \rightarrow \mathbb{R}^3$ is bendable or unbendable.

One way of modifying the concept of a bending is by taking a discrete analogue: We will call an imbedding $f: M \rightarrow \mathbb{R}^3$ **warpable** if there is an imbedding $g: M \rightarrow \mathbb{R}^3$ such that $f^*\langle \cdot, \cdot \rangle = g^*\langle \cdot, \cdot \rangle$, but such that g is not $A \circ f$ for any Euclidean motion A . If f is not warpable, it will be called **unwarpable**. We can also define a warpable immersion. It is conceivable that there is an imbedding $f: M \rightarrow \mathbb{R}^3$ such that

- (i) there exists an *immersion* $g: M \rightarrow \mathbb{R}^3$ with $f^*\langle \cdot, \cdot \rangle = g^*\langle \cdot, \cdot \rangle$,
- (ii) there does not exist an *imbedding* $g: M \rightarrow \mathbb{R}^3$ with $f^*\langle \cdot, \cdot \rangle = g^*\langle \cdot, \cdot \rangle$ except for g of the form $A \circ f$ for some Euclidean motion A ;

we can express this by saying that f is warpable as an immersion, but not as an imbedding (an actual example of this phenomenon will be mentioned later). A surface $M \subset \mathbb{R}^3$ is called warpable or unwarpable (as an imbedding or immersion) according as whether the inclusion map $i: M \rightarrow \mathbb{R}^3$ is warpable or unwarpable. An unwarpable surface $M \subset \mathbb{R}^3$ is sometimes called “uniquely determined” (for M is then uniquely determined, up to a Euclidean motion, by its induced metric); similarly, we can speak of an imbedding or immersion $f: M \rightarrow \mathbb{R}^3$ being “uniquely determined”. A bendable surface is obviously warpable, but it is not *a priori* clear whether there are any warpable surfaces which are not bendable.*

We can also consider an infinitesimal analogue of a bending α , by looking at its “variation vector field” Z . This is the vector field along f defined by

$$Z(p) = \text{tangent vector at } 0 \text{ of } t \mapsto \alpha(t, p) \in \mathbb{R}^3_{f(p)}.$$

*As if matters were not already sufficiently complicated, one more possibility must be mentioned, which for the sake of simplicity we shall describe in terms of submanifolds, rather than imbeddings. Let $M \subset \mathbb{R}^3$ be a surface. It is conceivable that M is warpable, so that there is an isometry $\phi: M \rightarrow \bar{M} \subset \mathbb{R}^3$ which is not the restriction of a Euclidean motion, but that whenever we have an isometry $\phi: M \rightarrow \bar{M}$ then there is also another isometry $\psi: M \rightarrow \bar{M}$ which is the restriction of a Euclidean motion. Thus M might be warpable, but only into surfaces which happen to be congruent to M . No example of such a phenomenon is known, however.

Consider for the moment the case where $M \subset \mathbb{R}^3$ and $f = \text{inclusion map}$. Since α satisfies

$$\langle X, Y \rangle = \langle \bar{\alpha}(t)_*(X), \bar{\alpha}(t)_*(Y) \rangle$$

for all t , and $X, Y \in M_p$, we have

$$\begin{aligned} (1) \quad 0 &= \frac{d}{dt} \langle \bar{\alpha}(t)_*(X), \bar{\alpha}(t)_*(Y) \rangle \\ &= \left\langle \frac{D'}{\partial t} \bar{\alpha}(t)_*(X), \bar{\alpha}(t)_*(Y) \right\rangle + \left\langle \bar{\alpha}(t)_*(X), \frac{D'}{\partial t} \bar{\alpha}(t)_*(Y) \right\rangle, \end{aligned}$$

where $D'/\partial t$ denotes covariant differentiation in the ambient space \mathbb{R}^3 , as usual. Now if c is a curve in M with $c'(0) = X$, then

$$\begin{aligned} \left. \frac{D'}{\partial t} \right|_{t=0} \bar{\alpha}(t)_*(X) &= \left. \frac{D'}{\partial t} \right|_{t=0} \left. \frac{\partial}{\partial s} \right|_{s=0} \alpha(t, c(s)) \\ &= \left. \frac{D'}{\partial s} \right|_{s=0} \left. \frac{\partial}{\partial t} \right|_{t=0} \alpha(t, c(s)) && \text{by Proposition II.6-9} \\ &&& \text{(or simply equality of mixed partials)} \\ &= \left. \frac{D'}{\partial s} \right|_{s=0} Z(c(s)) \\ &= \nabla'_X Z. \end{aligned}$$

So equation (1) becomes

$$(2) \quad 0 = \langle \nabla'_X Z, Y \rangle + \langle X, \nabla'_Y Z \rangle \quad \text{for all } X, Y \text{ tangent to } M.$$

This is equivalent, by polarization, to

$$(2') \quad 0 = \langle \nabla'_X Z, X \rangle \quad \text{for all } X \text{ tangent to } M,$$

and these equations can also be written

$$(2'') \quad \begin{cases} 0 = \langle dZ(X), X \rangle & \text{for all } X \text{ tangent to } M \\ 0 = \langle dZ(X), Y \rangle + \langle X, dZ(Y) \rangle & \text{for all } X, Y \text{ tangent to } M, \end{cases}$$

where Z is considered as an \mathbb{R}^3 -valued function on M , and the tangent vector X of \mathbb{R}^3 is identified with an element of \mathbb{R}^3 .

For the general case of an immersion $f: M \rightarrow \mathbb{R}^3$, the vector field Z along f still satisfies (2), except that now the term

$$\nabla'_X Z = \left. \frac{D'}{\partial s} \right|_{s=0} Z(c(s)) = \left(\left. \frac{dZ^1(c(s))}{ds} \right|_{s=0}, \dots, \left. \frac{dZ^3(c(s))}{ds} \right|_{s=0} \right)$$

denotes a “covariant derivative of a vector field along f ”. Equation (2'') becomes

$$(2''') \quad \begin{aligned} 0 &= \langle dZ(X), f_*(X) \rangle \\ &= \langle dZ(X), df(X) \rangle \quad \text{for all } X \text{ tangent to } M, \end{aligned}$$

where Z is considered as an \mathbb{R}^3 -valued function on M , and $f_*(X)$ is identified with an element of \mathbb{R}^3 , or f is considered as an \mathbb{R}^3 -valued function on M . This equation is sometimes written simply

$$\langle dZ, df \rangle = 0 \quad \text{or} \quad dZ \cdot df = 0.$$

[Note: Sometimes X (or German \mathfrak{X}) is used to denote the *immersion* $X: M \rightarrow \mathbb{R}^3$, and this equation appears as $dZ \cdot dX = 0$.]

A vector field Z along an immersion $f: M \rightarrow \mathbb{R}^3$ will be called an **infinitesimal bending** of f if it satisfies equation (2'''). Clearly this equation will be satisfied by the variation vector field of a variation α which merely “preserves lengths up to first order”, equation (1) being, in fact, the analytic expression of this condition. Of course, we can always find infinitesimal bendings by taking the variation vector field Z of a bending α by means of Euclidean motions,

$$\alpha(t, p) = f(p) \cdot B(t) + v(t),$$

where $B(t) \in O(3)$ with $B(0) = I$, and $v(t) \in \mathbb{R}^3$ with $v(0) = 0$ [and $f(p) \cdot B(t)$ denotes the product of the 1×3 matrix $f(p)$ with the 3×3 matrix $B(t)$]. In this case we have

$$Z(p) = f(p) \cdot B'(0) + v'(0),$$

where $B'(t) \in \mathfrak{o}(3) = \{3 \times 3 \text{ skew-symmetric matrices}\}$. Conversely, if Z is an infinitesimal bending of f of the form

$$(3) \quad Z(p) = f(p) \cdot C + w, \quad C \in \mathfrak{o}(3),$$

then Z is the variation vector field of the bending α through Euclidean motions defined by

$$\alpha(t, p) = f(p) \cdot e^{tC} + tw.$$

So we will call an infinitesimal bending Z **trivial** if it is of the form (3). An immersion $f: M \rightarrow \mathbb{R}^3$ will be called **infinitesimally bendable** if there is a non-trivial infinitesimal bending of f ; otherwise it will be called **infinitesimally rigid**. (The word “rigid” is sometimes used to mean infinitesimally rigid, but unfortunately it is also sometimes sloppily used to mean unwarpable, or unbendable.)

Notice that the product of a vector by a skew-symmetric matrix,

$$(x, y, z) \cdot \begin{pmatrix} 0 & -a & -b \\ a & 0 & -c \\ b & c & 0 \end{pmatrix} = (ay + bz, -ax + cz, -bx - cy),$$

can also be written as a cross-product

$$(x, y, z) \times (c, -b, a) = (ay + bz, -ax + cz, -bx - cy).$$

So equation (3) can also be written

$$(3') \quad Z(p) = f(p) \times Y + w, \quad Y, w \in \mathbb{R}^3.$$

As an easy consequence of the triviality condition (3') we have

$$dZ(X) = df(X) \times Y \quad \text{all } X \text{ tangent to } M.$$

Now the same formula holds for an arbitrary infinitesimal bending Z , provided that we allow Y to vary:

3. LEMMA. If Z is an infinitesimal bending of $f: M \rightarrow \mathbb{R}^3$, then for each $p \in M$, there is a unique $Y(p) \in \mathbb{R}^3$ such that

$$dZ(X) = df(X) \times Y(p) \quad \text{for all } X \in M_p.$$

PROOF. Let $X_1, X_2 \in M_p$ be linearly independent. Since $\langle dZ(X_i), df(X_i) \rangle = 0$, there are certainly some vectors $Y_i \in \mathbb{R}^3$ with

$$dZ(X_i) = df(X_i) \times Y_i.$$

Moreover,

$$\begin{aligned} 0 &= \langle dZ(X_2), df(X_1) \rangle + \langle dZ(X_1), df(X_2) \rangle \\ &= \langle df(X_2) \times Y_2, df(X_1) \rangle + \langle df(X_1) \times Y_1, df(X_2) \rangle \\ &= \langle Y_2, df(X_1) \times df(X_2) \rangle - \langle Y_1, df(X_1) \times df(X_2) \rangle \\ &= \langle Y_2 - Y_1, df(X_1) \times df(X_2) \rangle. \end{aligned}$$

Thus $Y_2 - Y_1 \in df(M_p)$, so we can write

$$Y_2 - Y_1 = a df(X_1) + b df(X_2).$$

If we set

$$Y(p) = Y_2 - a df(X_1) = Y_1 + b df(X_2)$$

then we have

$$dZ(X_i) = df(X_i) \times Y_i = df(X_i) \times Y(p).$$

Uniqueness is obvious. ♦

The vector field $p \mapsto Y(p)$ of Lemma 3 is called the **(infinitesimal) rotation field** of the infinitesimal bending Z . We know that Y is constant when Z is trivial, and conversely,

4. LEMMA. If the rotation field Y of the infinitesimal bending Z is constant, then Z is trivial.

PROOF. By assumption, there is a vector $Y_0 \in \mathbb{R}^3$ with

$$dZ(X) = df(X) \times Y_0$$

for all X tangent to M . Let c be a curve in M , with $c(0) = p_0 \in M$. Then

$$\frac{dZ(c(t))}{dt} = dZ(c'(t)) = df(c'(t)) \times Y_0 = \frac{df(c(t))}{dt} \times Y_0.$$

Therefore

$$Z(c(t)) - Z(p_0) = [f(c(t)) - f(p_0)] \times Y_0,$$

or

$$Z(c(t)) = f(c(t)) \times Y_0 + w_0,$$

where $w_0 \in \mathbb{R}^3$ does not depend on c . So for all $p \in M$ we have

$$Z(p) = f(p) \times Y_0 + w_0,$$

and Z is trivial. ♦

At first sight it might seem that every bendable surface must also be infinitesimally bendable. As a matter of fact, we certainly do have

5. LEMMA. Let $\alpha: [0, 1] \times M \rightarrow \mathbb{R}^3$ be a bending, and let Z_t be the variation vector field of α at time t . If each Z_t is trivial, then the bending α is trivial.

PROOF. By definition,

$$(1) \quad Z_t(p) = \frac{d}{dt} \alpha(t, p),$$

and since each Z_t is trivial we have

$$(2) \quad Z_t(p) = \alpha(t, p) \times Y_t + w_t \quad Y_t, w_t \in \mathbb{R}^3.$$

Then for all $p_1, p_2 \in M$ we have

$$\begin{aligned} \frac{d}{dt} |\alpha(t, p_1) - \alpha(t, p_2)|^2 &= 2 \langle \alpha(t, p_1) - \alpha(t, p_2), Z_t(p_1) - Z_t(p_2) \rangle \quad \text{by (I)} \\ &= 2 \langle \alpha(t, p_1) - \alpha(t, p_2), [\alpha(t, p_1) - \alpha(t, p_2)] \times Y_t \rangle \\ &= 0. \end{aligned}$$

So $|\alpha(t, p_1) - \alpha(t, p_2)|$ is constant in t . In particular, $|\alpha(t, p_1) - \alpha(t, p_2)| = |\alpha(0, p_1) - \alpha(0, p_2)|$. This implies that each α_t differs by a Euclidean motion from α_0 . ♦

Nevertheless, it is conceivable that $f: M \rightarrow \mathbb{R}^3$ is bendable, yet that every bending α of f has trivial variation vector field Z_0 at time $t = 0$, so that f is not infinitesimally bendable. No example of such a weird phenomenon is known, but there are also no positive results along this line, except for the obvious fact that if f is an analytic immersion which is analytically infinitesimally rigid, then f is analytically unbendable.

There are a couple of other surprising facts about infinitesimal bendings. First of all, there are non-trivial infinitesimal bendings Z of a plane which vanish outside a compact set. If our plane is the (x, y) -plane, we can choose Z to be $h \cdot \frac{\partial}{\partial z}$, where h is any C^∞ function vanishing outside a compact set. For any

tangent vector X of the (x, y) -plane we have

$$dZ(X) = (X(0), X(0), X(h)) = X(h) \cdot \frac{\partial}{\partial z},$$

so the infinitesimal rotation vector field of Z is

$$Y = X(h) \cdot \frac{\partial}{\partial z}.$$

Since Y is not constant, Z is non-trivial. Even more surprising, perhaps, is an immediate consequence of this fact: any surface containing a portion of a plane is infinitesimally bendable.

Notice that the infinitesimal bending Z constructed above is everywhere perpendicular to the surface $M = (x, y)$ -plane. This is essentially the only possibility:

6. LEMMA. (1) If Z is an infinitesimal bending of an open subset M of the (x, y) -plane, and Z is always tangential to the (x, y) -plane, then Z is trivial,

$$Z(p) = p \cdot C + v$$

for a 2×2 skew-symmetric matrix C , and $v \in (x, y)$ -plane.

(2) More generally, Z is an infinitesimal bending of $M \subset (x, y)$ -plane if and only if the tangential component $\mathbb{T}Z$ of Z is an infinitesimal bending, and hence trivial. In particular, any vector field Z normal to M is an infinitesimal bending.

(3) Let $M \subset \mathbb{R}^3$ be a surface and let Z be any infinitesimal bending of M which is everywhere normal to M . Then at every point $p \in M$ where $Z(p) \neq 0$, the second fundamental form $\Pi(p) = 0$. (So if $Z(p) \neq 0$ for all p in an open set $U \subset M$, then U lies in a plane.)

PROOF. (1) Let

$$Z(x, y) = (a(x, y), b(x, y)) = a(x, y) \frac{\partial}{\partial x} + b(x, y) \frac{\partial}{\partial y}.$$

Then

$$dZ \left(\frac{\partial}{\partial x} \right) = \frac{\partial a}{\partial x} \cdot \frac{\partial}{\partial x} + \frac{\partial b}{\partial x} \cdot \frac{\partial}{\partial y}, \quad dZ \left(\frac{\partial}{\partial y} \right) = \frac{\partial a}{\partial y} \cdot \frac{\partial}{\partial x} + \frac{\partial b}{\partial y} \cdot \frac{\partial}{\partial y}.$$

Thus

$$0 = \left\langle \frac{\partial}{\partial x}, dZ \left(\frac{\partial}{\partial x} \right) \right\rangle \implies \frac{\partial a}{\partial x} = 0$$

$$0 = \left\langle \frac{\partial}{\partial y}, dZ \left(\frac{\partial}{\partial y} \right) \right\rangle \implies \frac{\partial b}{\partial y} = 0$$

so we can write

$$a(x, y) = \bar{a}(y), \quad b(x, y) = \bar{b}(x).$$

Moreover,

$$0 = \left\langle \frac{\partial}{\partial x}, dZ \left(\frac{\partial}{\partial y} \right) \right\rangle + \left\langle \frac{\partial}{\partial y}, dZ \left(\frac{\partial}{\partial x} \right) \right\rangle \implies \bar{a}'(y) + \bar{b}'(x) = 0.$$

Since this is true for all x, y , the derivatives $\bar{a}'(y)$ and $\bar{b}'(x)$ must be constants. So we must have

$$a(x, y) = \bar{a}(y) = \alpha y + \beta$$

$$b(x, y) = \bar{b}(x) = -\alpha x + \delta.$$

Then

$$Z(x, y) = (x, y) \cdot \begin{pmatrix} 0 & -\alpha \\ \alpha & 0 \end{pmatrix} + (\beta, \delta).$$

This completes the proof of (1).

Now for any $M \subset \mathbb{R}^3$, with unit normal ν , consider a vector field

$$Z = \mathbb{T}Z + \phi \cdot \nu.$$

Then for $X \in M_p$ we have

$$\nabla'_X Z = \nabla_X \mathbb{T}Z + \text{II}(X, \mathbb{T}Z) \cdot \nu + X(\phi) \cdot \nu - \phi(p) d\nu(X).$$

So $0 = \langle \nabla'_X Z, X \rangle$ if and only if

$$(*) \quad \langle \nabla_X \mathbb{T}Z, X \rangle = \phi(p) \cdot \text{II}(X, X).$$

If $M \subset (x, y)$ -plane, then $\text{II}(X, X) = 0$ and $\text{II}(X, \mathbb{T}Z) = 0$, so $(*)$ says that Z is an infinitesimal bending if and only if $0 = \langle \nabla_X \mathbb{T}Z, X \rangle = \langle \nabla'_X \mathbb{T}Z, X \rangle$ for all X , so that $\mathbb{T}Z$ is an infinitesimal bending. This proves (2).

On the other hand, if Z is an infinitesimal bending with $\mathbb{T}Z = 0$, and $\phi(p) \neq 0$, then $(*)$ shows that $\text{II}(X, X) = 0$ for all $X \in M_p$. This proves (3). ♦

There also turns out to be a relationship between warpability and infinitesimal bendability, which at first sight seem to have nothing to do with each other.

7. LEMMA. Let Z be an infinitesimal bending of an immersion $f: M \rightarrow \mathbb{R}^3$. Define $\alpha_t: M \rightarrow \mathbb{R}^3$ by

$$\alpha_t(p) = f(p) + t \cdot Z(p),$$

where $Z(p)$ is considered as an element of \mathbb{R}^3 as usual. Then in a neighborhood of any point $p \in M$, the map α_t is an immersion for sufficiently small t , and the induced metric $\alpha_t^* \langle \cdot, \cdot \rangle$ on M is related to the metric $f^* \langle \cdot, \cdot \rangle$ by

$$[\alpha_t^* \langle \cdot, \cdot \rangle](X, Y) = [f^* \langle \cdot, \cdot \rangle](X, Y) + t^2 \langle dZ(X), dZ(Y) \rangle.$$

In particular, the metrics $\alpha_t^* \langle \cdot, \cdot \rangle$ and $\alpha_{-t}^* \langle \cdot, \cdot \rangle$ on M are the same.

PROOF. If X is a tangent vector on M , with $X = c'(0)$ for some curve c in M , then

$$\begin{aligned}\alpha_{t*}X &= \left. \frac{d}{ds} \right|_{s=0} \alpha_t(c(s)) \\ &= \left. \frac{d}{ds} \right|_{s=0} c(s) + t Z(c(s)) \\ &= c'(0) + t dZ(c'(0)) \\ &= X + t dZ(X).\end{aligned}$$

This immediately leads to the desired formula, and this formula shows that α_t is an immersion for small t , in any neighborhood of p on which Z is bounded. ♦

An illustration of this phenomenon is provided by the infinitesimal bending Z of the (x, y) -plane given previously. The map taking $p + tZ(p) \mapsto p - tZ(p)$

is the restriction of a Euclidean motion, namely reflection through the (x, y) -plane. But this is the *only* case in which this happens:

8. LEMMA. Let Z be a non-trivial infinitesimal bending of a surface $M \subset \mathbb{R}^3$ which is not part of a plane. Then for $t \neq 0$, the map

$$p + tZ(p) \mapsto p - tZ(p)$$

[which is an isometry by Lemma 7] is not the restriction of a Euclidean motion.

PROOF. If this map is the restriction of a length preserving map of \mathbb{R}^3 , then for all $p, q \in M$ we have

$$|p + tZ(p) - \{q + tZ(q)\}| = |p - tZ(p) - \{q - tZ(q)\}|,$$

that is,

$$|p - q + t\{Z(p) - Z(q)\}| = |p - q - t\{Z(p) - Z(q)\}|.$$

This implies that

$$(1) \quad \langle p - q, Z(p) - Z(q) \rangle = 0.$$

Without loss of generality, we may assume that M contains the point 0, and that $Z(0) = 0$. Then equation (1) gives

$$\langle p, Z(p) \rangle = 0 \quad p \in M,$$

from which we further deduce that

$$(2) \quad \langle p, Z(q) \rangle + \langle q, Z(p) \rangle = 0, \quad p, q \in M.$$

Since M is not contained in a plane, there are three linearly independent points $r_1, r_2, r_3 \in M$. Now if λ_i are numbers with $\sum_i \lambda_i r_i \in M$, then

$$\begin{aligned} \langle Z(\sum_i \lambda_i r_i), r_j \rangle &= -\langle \sum_i \lambda_i r_i, Z(r_j) \rangle && \text{by (2)} \\ &= -\sum_i \lambda_i \langle r_i, Z(r_j) \rangle \\ &= \sum_i \lambda_i \langle Z(r_i), r_j \rangle && \text{by (2)} \\ &= \langle \sum_i \lambda_i Z(r_i), r_j \rangle. \end{aligned}$$

This implies that

$$Z(\sum_i \lambda_i r_i) = \sum_i \lambda_i Z(r_i).$$

So Z is the restriction to M of a linear transformation T . Since a linear transformation is its own derivative, equation (2'') shows that

$$0 = \langle TX, Y \rangle + \langle X, TY \rangle$$

for all pairs of vectors X, Y which are in some M_p (when M_p is identified with a subspace of \mathbb{R}^3 in the usual way). Since M is not contained in a plane, there are three distinct subspaces $M_{p_1}, M_{p_2}, M_{p_3}$ (we regard these as vector subspaces of \mathbb{R}^3). Choose

$$X_3 \in M_{p_1} \cap M_{p_2}$$

$$X_2 \in M_{p_1} \cap M_{p_3}$$

$$X_1 \in M_{p_2} \cap M_{p_3}.$$

Then the X_i are linearly independent, and $0 = \langle TX_i, X_j \rangle + \langle X_i, TX_j \rangle$ for each i, j . This implies that $0 = \langle TX, Y \rangle + \langle X, TY \rangle$ for all $X, Y \in \mathbb{R}^3$. Thus T is skew-adjoint, and its matrix C is skew-symmetric. In other words,

$$Z(p) = p \cdot C \quad C \in \mathfrak{o}(3),$$

and hence Z is trivial. ♦

In order to obtain some deeper results about rigidity, we will find it useful to consider various \mathbb{R}^3 -valued differential forms on a surface M . Many of these forms will be defined in terms of other \mathbb{R}^3 -valued forms and functions on M by means of the inner product and cross product on \mathbb{R}^3 . If $f, g: M \rightarrow \mathbb{R}^3$ are two functions, then there is only one reasonable meaning for $f \times g$, namely the function

$$p \mapsto f(p) \times g(p) \in \mathbb{R}^3.$$

But if ω and η are \mathbb{R}^3 -valued 1-forms on M , then $\omega \times \eta$ might mean any of the following operations on tangent vectors:

$$\begin{aligned} X &\mapsto \omega(X) \times \eta(X) && \text{(a quadratic function)} \\ (X, Y) &\mapsto \omega(X) \times \eta(Y) && \text{(a bilinear function)} \\ (X, Y) &\mapsto \omega(X) \times \eta(Y) - \omega(Y) \times \eta(X) && \text{(a 2-form).} \end{aligned}$$

To distinguish these possibilities, we might write the last two as

$$\omega \overset{\otimes}{\times} \eta \quad \text{and} \quad \omega \overset{\wedge}{\times} \eta.$$

Since we shall, in fact, only be interested in the last case, we will introduce the simpler symbol \mathbf{x} and define

$$\omega \mathbf{x} \eta(X, Y) = \omega(X) \times \eta(Y) - \omega(Y) \times \eta(X).$$

The present situation is actually just a special case of the one already considered at the end of Chapter I.10; see pg. I.403 and especially Problems I.10-20 and 10-21. In general, if ω and η are \mathbb{R}^3 -valued forms of degree k and l , respectively, then we define a $(k+l)$ -form $\omega \mathbf{x} \eta$ by

$$\begin{aligned} &\omega \mathbf{x} \eta(X_1, \dots, X_k, X_{k+1}, \dots, X_{k+l}) \\ &= \frac{1}{k!l!} \sum_{\sigma \in S_{k+l}} \text{sgn } \sigma \cdot \omega(X_{\sigma(1)}, \dots, X_{\sigma(k)}) \times \eta(X_{\sigma(k+1)}, \dots, X_{\sigma(k+l)}). \end{aligned}$$

[Actually, since we will be dealing with a surface M , only the cases $k, l \leq 1$ are relevant.] In an exactly analogous way, we define $\omega \bullet \eta$, using the product

$v \cdot w = \langle v, w \rangle$ in \mathbb{R}^3 . Then we have (Problem I.10-21(a))

$$\begin{aligned} d(\omega \times \eta) &= d\omega \times \eta + (-1)^k \omega \times d\eta \\ d(\omega \cdot \eta) &= d\omega \cdot \eta + (-1)^k \omega \cdot d\eta. \end{aligned}$$

Notice that since \times is not commutative, $\omega \times \omega$ need not be zero. In fact, for a 1-form ω we have

$$\omega \times \omega(X, Y) = 2\omega(X) \times \omega(Y).$$

More generally,

$$\begin{aligned} \omega \times \eta &= (-1)^{kl+1} \eta \times \omega \\ \omega \cdot \eta &= (-1)^{kl} \eta \cdot \omega. \end{aligned}$$

It is also easy to see that the formula

$$v \cdot (w \times z) = -w \cdot (v \times z) \quad v, w, z \in \mathbb{R}^3$$

leads to the relation

$$\omega \cdot (\eta \times \lambda) = (-1)^{kl+1} \eta \cdot (\omega \times \lambda).$$

Pure notational fiddling would lead us to write $\omega \cdot (\eta \times \lambda)$ in the form **det**(ω, η, λ), which can be defined directly in an obvious way: if $\omega = (\omega^1, \omega^2, \omega^3)$ for ordinary 1-forms ω^i , and similarly for η and λ , then **det**(ω, η, λ) denotes

$$\det \begin{pmatrix} \omega^1 & \omega^2 & \omega^3 \\ \lambda^1 & \lambda^2 & \lambda^3 \\ \eta^1 & \eta^2 & \eta^3 \end{pmatrix},$$

where the determinant is expanded out as usual, with all multiplications being replaced by \wedge , and care being taken to write products in the correct order (namely, the same order as the columns they appear in). One easily checks, either from this definition, or from the alternative form $\omega \cdot (\eta \times \lambda)$, that

$$\begin{aligned} d \mathbf{det}(\omega, \eta, \lambda) &= \mathbf{det}(d\omega, \eta, \lambda) + (-1)^k \mathbf{det}(\omega, d\eta, \lambda) \\ &\quad + (-1)^{k+l} \mathbf{det}(\omega, \eta, d\lambda). \end{aligned}$$

We will frequently use the various formulas given here without specific comment.

Now consider an immersion $f: M \rightarrow \mathbb{R}^3$ of an oriented surface M , and the corresponding normal map $N: M \rightarrow \mathbb{R}^3$. If dA is the volume element of M

for the metric $f^*\langle \ , \ \rangle$, then we have the following identities among \mathbb{R}^3 -valued 2-forms on M :

$$\begin{aligned} \text{(I)} \quad & df \times df = 2N dA \\ \text{(II)} \quad & df \times dN = -2HN dA \\ \text{(III)} \quad & dN \times dN = 2KN dA. \end{aligned}$$

To prove these simple relations, pick vectors $X_1, X_2 \in M_p$ with (X_1, X_2) positively oriented. Now $df(X_i)$ is just $f_*(X_i)$, considered as an element of \mathbb{R}^3 . So

$$\begin{aligned} df \times df(X_1, X_2) &= 2 df(X_1) \times df(X_2) \\ &= 2N(p) \cdot \text{area of parallelogram spanned by } df(X_1), df(X_2) \\ &= 2N(p) \cdot dA(X_1, X_2). \end{aligned}$$

Moreover, if

$$\begin{aligned} dN(X_1) &= \alpha df(X_1) + \beta df(X_2) \\ dN(X_2) &= \gamma df(X_1) + \delta df(X_2), \end{aligned}$$

then

$$\begin{aligned} df \times dN(X_1, X_2) &= \delta df(X_1) \times df(X_2) - \alpha df(X_2) \times df(X_1) \\ &= (\alpha + \delta) df(X_1) \times df(X_2) \\ &= (\alpha + \delta)N(p) dA(X_1, X_2) \\ &= -2H(p)N(p) dA(X_1, X_2), \end{aligned}$$

and

$$\begin{aligned} dN \times dN(X_1, X_2) &= 2 dN(X_1) \times dN(X_2) \\ &= 2[\alpha df(X_1) + \beta df(X_2)] \times [\gamma df(X_1) + \delta df(X_2)] \\ &= 2(\alpha\delta - \beta\gamma) df(X_1) \times df(X_2) \\ &= 2K(p)N(p) dA(X_1, X_2). \end{aligned}$$

Naturally, all these formulas can be applied when $M \subset \mathbb{R}^3$, and f is just the inclusion map $i: M \rightarrow \mathbb{R}^3$. And, in fact, we shall usually apply them to imbedded, rather than immersed, surfaces. But it nevertheless seems conceptually easier always to regard M as an abstract surface sitting off in the void, so that f and N can be thought of simply as certain \mathbb{R}^3 -valued functions on M without worrying about the geometry they induce; most of the geometric information in question is already presented in formulas (I)–(III).

We will also need to recall the **support function** $h = -f \cdot N: M \rightarrow \mathbb{R}^3$, which is defined in Problem 3-7. As we saw, $h(p)$ is the signed distance from the origin to the tangent plane of $f(M)$ at $f(p)$; when f is an imbedding with

$f(M)$ star-shaped with respect to 0, and N is inward pointing, it is precisely this distance. This happens, in particular, when $f(M)$ is convex, and 0 lies inside it.

Now consider the \mathbb{R}^3 -valued 1-form α on M defined by

$$\alpha = (f \times N) \cdot df.$$

We have

$$\begin{aligned} d\alpha &= (df \times N) \cdot df + (f \times dN) \cdot df \\ &= -N \cdot (df \times df) + f \cdot (dN \times df) \quad \text{[the dots do not have to be bold since } f \text{ and } N \text{ are functions]} \\ &= -2dA - 2H(f \cdot N) dA \quad \text{by (I) and (II)} \\ &= -2dA + 2hH dA. \end{aligned}$$

If M is compact, then $\int_M d\alpha = \int_{\partial M} \alpha = 0$, so we obtain

$$(IV) \quad \text{area}(M) = \int_M hH dA.$$

Similarly, for the 1-form

$$\beta = (f \times N) \cdot dN,$$

we have

$$\begin{aligned} d\beta &= (df \times N) \cdot dN + (f \times dN) \cdot dN \\ &= -N \cdot (df \times dN) + f \cdot (dN \times dN) \\ &= 2H dA - 2hK dA \quad \text{by (II) and (III)}. \end{aligned}$$

Hence for compact M we have

$$(V) \quad \int_M H \, dA = \int_M hK \, dA.$$

Equations (IV) and (V) are sometimes called *Minkowski's formulas*.

As a first application of these formulas, we reprove a rigidity result which appeared a long time ago. The theorem that a compact surface with constant $K > 0$ must be a (standard) sphere in \mathbb{R}^3 can also be stated as follows: a sphere is unwarpable.* To prove this from our present formulas, we consider any compact surface $M \subset \mathbb{R}^3$ with constant $K > 0$. It is convex, by Hadamard's theorem, and we can assume that $0 \in \mathbb{R}^3$ lies in its interior, so that the support function h is always positive for the inward pointing N . There is no loss of generality in assuming that $K = k_1 k_2 = 1$. Since for $x > 0$ we always have

$$x + \frac{1}{x} \geq 2,$$

with equality only if $x = 1$, this implies that

$$H = \frac{1}{2} \left(k_1 + \frac{1}{k_1} \right) \geq 1,$$

with equality only if $k_1 = k_2$. So

$$\begin{aligned} \int_M h \, dA &= \int_M H \, dA && \text{by (V)} \\ &\geq \int_M dA \\ &= \int_M hH \, dA && \text{by (IV),} \end{aligned}$$

and consequently

$$\int_M h(1 - H) \, dA \geq 0.$$

Since $h > 0$ everywhere, and $1 - H \leq 0$ everywhere, it follows that $H = 1$ everywhere. This implies that $k_1 = k_2$ everywhere.

*Actually, the statement that a sphere is unwarpable is formally *stronger* than the statement that any compact surface isometric to a sphere is a sphere—see the footnote on page 171. But the complete equivalence of the two statements follows easily from the fact that any isometry of a sphere onto itself is the restriction of a Euclidean motion.

Similarly, we can reprove Theorem 5-3, and in a little greater generality.

9. PROPOSITION. The only star-shaped surfaces of constant mean curvature H are spheres.

PROOF. We still have $h > 0$, and there is no loss of generality in assuming that

$$1 = H = \frac{k_1 + k_2}{2}.$$

Then

$$K = k_1 k_2 = k_1(2 - k_1) = 2k_1 - (k_1)^2 \leq 1,$$

with equality only if $k_1 = 1$. Now

$$\begin{aligned} \int_M h dA &= \int_M dA && \text{by (IV)} \\ &= \int_M hK dA && \text{by (V),} \end{aligned}$$

so

$$\int_M h(1 - K) dA = 0.$$

Thus we must have $K = 1$ everywhere, hence $k_1 = 1$ everywhere, hence $k_2 = 1 = k_1$ everywhere. ♦

This proof is mainly a curiosity, since, as we showed in Chapter 9 (Addendum 2 or 3), a much stronger result actually holds. By considering another \mathbb{R}^3 -valued 1-form, however, we obtain a real theorem, one of the first in the subject.

10. THEOREM. Let $M \subset \mathbb{R}^3$ be any compact convex surface which does not contain a portion of a plane. Then M is infinitesimally rigid.

Remarks: (1) We have already pointed out that the conclusion fails if M does contain a portion of a plane.

(2) We could replace convexity with the hypothesis $K \geq 0$ (see the remark after Theorem 2-11 or Proposition 7-32).

PROOF. For simplicity, we first consider the case where $K > 0$ everywhere. Let Z be an infinitesimal bending of the inclusion map $f: M \rightarrow \mathbb{R}^3$, and let Y be its rotation field, so that

$$dZ(X_p) = df(X_p) \times Y(p)$$

for all $X_p \in M_p$. This relation can be written in terms of the \mathbb{R}^3 -valued 1-forms dZ and df , and \mathbb{R}^3 -valued function Y , as

$$dZ = df \times Y.$$

Now

$$(1) \quad 0 = d(dZ) = -df \times dY.$$

This means that for $X_1, X_2 \in M_p$ we have

$$(2) \quad df(X_1) \times dY(X_2) - df(X_2) \times dY(X_1) = 0.$$

Taking the dot product of this equation with $df(X_1)$ and $df(X_2)$, we find that $dY(X_i)$ lies in the plane spanned by $df(X_1)$ and $df(X_2)$, which is nothing but the tangent plane M_p moved over to the origin. In other words, we can consider dY as a map $dY: M_p \rightarrow M_p$.

Now choose a moving frame X_1, X_2 in a neighborhood of p . We can write

$$(3) \quad \begin{aligned} dY(X_1) &= \alpha df(X_1) + \beta df(X_2) \\ dY(X_2) &= \gamma df(X_1) + \delta df(X_2) \end{aligned}$$

for some functions $\alpha, \beta, \gamma, \delta$. Equation (1) implies that

$$(4) \quad \alpha + \delta = 0.$$

Remembering that f is just the inclusion map, so that X_1, X_2 are vector fields on M , we can write

$$(5) \quad \begin{aligned} 0 &= d(dY)(X_1, X_2) = X_1(dY(X_2)) - X_2(dY(X_1)) - dy([X_1, X_2]) \\ &= \gamma \nabla'_{X_1} X_1 + \delta \nabla'_{X_1} X_2 - \alpha \nabla'_{X_2} X_1 - \beta \nabla'_{X_2} X_2 \\ &\quad + \text{something tangent to } M. \end{aligned}$$

Taking the inner product with N , and using (4), we get

$$\begin{aligned} 0 &= \gamma \Pi(X_1, X_1) - 2\alpha \Pi(X_1, X_2) - \beta \Pi(X_2, X_2) \\ &= \gamma l - 2\alpha m - \beta n, \quad \text{say.} \end{aligned}$$

In particular, suppose that we choose X_1, X_2 to be principal vectors at some point p , so that at p we have $m = 0$. Then our equation is simply

$$(6) \quad 0 = \gamma l - \beta n.$$

Since $K = ln > 0$, this shows that γ and β have the same sign. So

$$0 \leq \beta\gamma \quad \text{and} \quad 0 = \beta\gamma \quad \text{only if} \quad \beta = \gamma = 0.$$

Hence at each point p we have

$$(7) \quad 0 \leq \alpha^2 + \beta\gamma = -\det dY$$

with equality only if $\alpha = \beta = \gamma = 0 \implies dY = 0$.

Consider the 1-form

$$\omega = (f \times Y) \cdot dY$$

(closely related to the 1-form β considered previously). We have

$$\begin{aligned} d\omega &= (df \times Y) \cdot dY + (f \times dY) \cdot dY \\ &= -Y \cdot (df \times dY) + f \cdot (dY \times dY) \\ &= 0 + f \cdot (dY \times dY) \quad \text{by (I).} \end{aligned}$$

But we also have

$$dY \times dY = 2(\det dY)N dA,$$

by the very same argument which proved formula (III). Hence

$$d\omega = 2h(\det dY) dA.$$

So for our compact manifold M we have the *integral formula of Blaschke*:

$$(*) \quad \int_M h(\det dY) dA = 0.$$

Since $h > 0$, and $\det dY \leq 0$ by (7), we must have $\det dY = 0$ everywhere. Then (7) also shows that $dY = 0$ everywhere. Therefore Y is constant. So Z is trivial by Lemma 4.

Now we consider the case where $K \geq 0$, but M contains no portion of a plane, so that the planar points of M are nowhere dense. At a parabolic point we have $n = 0$ and $l \neq 0$, say. Equation (6) then shows that $\gamma = 0$. Hence we still have

$$0 \leq \alpha^2 + \beta\gamma = -\det dY.$$

Thus we have $\det dY \leq 0$ at all non-planar points, which implies that $\det dY \leq 0$ everywhere. So we can still conclude from (*) that $\det dY = 0$ everywhere. We want to show that consequently $dY = 0$ everywhere; it obviously suffices to show that $dY(p) = 0$ when p is a parabolic point.

If the parabolic point p lies in the closure of $\{q \in M : K(q) > 0\}$, then clearly $dY(p) = 0$. So consider a parabolic point p which has a neighborhood on which $K = 0$. By Proposition 5-4 and Corollary 5-6, M contains a ruled surface

$$(s, t) \mapsto c(s) + td(s), \quad |d| = 1 \implies \langle d, d' \rangle = 0$$

around p such that the ruling through p has its endpoints in the closure of $\{q \in M : K(q) > 0\}$, and consequently $dY = 0$ at the endpoints of this ruling. We can choose the curve c to be the intersection of the ruled surface with a

plane perpendicular to the ruling through p . So if X_1, X_2 are the coordinate vector fields

$$\begin{aligned} X_1(s, t) &= c'(s) + td'(s) \\ X_2(s, t) &= d(s), \end{aligned}$$

then along the ruling through p we have

$$\langle X_1, X_2 \rangle = \langle c' + td', d \rangle = \langle c', d \rangle = 0.$$

Now X_2 is the principal vector with principal curvature $n = 0$. So along the ruling through p , the vector field X_1 is the other principal vector, with principal curvature $l \neq 0$. So we have [by (6)]

$$(8) \quad \gamma = 0 \quad \text{along the ruling through } p.$$

Since we have $0 = -\det Y = \alpha^2 + \beta\gamma$ everywhere, we also have

$$(9) \quad \alpha = 0 \quad \text{along the ruling through } p.$$

So equations (3) and (4) give

$$\begin{aligned} dY(X_1) &= \beta df(X_2) \\ dY(X_2) &= 0 \end{aligned} \quad \text{along the ruling through } p.$$

Then equation (5) becomes simply

$$\begin{aligned} 0 &= 0 - X_2(\beta df(X_2)) - 0 \\ &= -X_2(\beta) df(X_2) - \beta \nabla'_{X_2} X_2 \\ &= -X_2(\beta) df(X_2). \end{aligned}$$

Thus $0 = X_2(\beta)$ along the ruling through p , so that β is constant on this ruling. But $\beta = 0$ at the endpoints, since $dY = 0$ at the endpoints. It follows that also $\beta = 0$ at p ; together with (8) and (9) we now have $dY(p) = 0$. ♦

At this point it might be nice to have some non-trivial examples of surfaces which *are* infinitesimally bendable. Consider a surface given as a graph,

$$f(x, y) = (x, y, u(x, y));$$

we introduce the standard notation

$$\begin{aligned} p &= u_1 = \frac{\partial u}{\partial x}, & q &= \frac{\partial u}{\partial y} \\ r &= \frac{\partial^2 u}{\partial x^2}, & s &= \frac{\partial^2 u}{\partial x \partial y}, & t &= \frac{\partial^2 u}{\partial y^2}. \end{aligned}$$

Suppose that $Z = (_, _, \zeta)$ is an infinitesimal bending, with rotation field $Y = (\alpha, \beta, \psi)$. Then

$$\begin{aligned} (_, _, \zeta_1) &= dZ \left(\frac{\partial}{\partial x} \right) = df \left(\frac{\partial}{\partial x} \right) \times (\alpha, \beta, \psi) \\ &= (1, 0, p) \times (\alpha, \beta, \psi) \\ &= (_, _, \beta) \end{aligned}$$

and similarly

$$(_, _, \zeta_2) = (_, _, -\alpha).$$

So Y must be of the form

$$Y = (-\zeta_2, \zeta_1, \psi).$$

Using equation (2) in the proof of Theorem 10, we see that we must have

$$(1, 0, p) \times (-\zeta_{22}, \zeta_{12}, \psi_2) - (0, 1, q) \times (-\zeta_{12}, \zeta_{11}, \psi_1) = 0,$$

which is equivalent to

$$(*) \quad \begin{cases} \psi_1 = q\zeta_{11} - p\zeta_{12} \\ \psi_2 = -q\zeta_{12} + p\zeta_{22}. \end{cases}$$

Conversely, if ψ_i, ζ_{ij} satisfy these equations, and we define the vector-valued 1-form W by

$$W(X) = df(X) \times (-\zeta_2, \zeta_1, \psi),$$

then W will satisfy $dW = 0$, so on any simply-connected portion of the (x, y) -plane there will be Z with $dZ = W$. Now equations $(*)$ can be solved for ψ if and only if

$$(q\zeta_{11} - p\zeta_{12})_2 = (-q\zeta_{12} + p\zeta_{22})_1,$$

which leads to an equation for ζ :

$$(**) \quad r\zeta_{22} - 2s\zeta_{12} + t\zeta_{11} = 0.$$

As a particular case, we consider the paraboloid $u(x, y) = \frac{1}{2}(x^2 + y^2)$. We obtain the equation

$$\zeta_{11} + \zeta_{22} = 0,$$

whose solutions are the real part of any entire function on $\mathbb{C} = \mathbb{R}^2$. Thus there are non-trivial infinitesimal bendings of $\{(x, y, u(x, y))\}$, which is a complete convex surface.

As we have already pointed out, it is not known whether infinitesimal rigidity generally implies unbendability. But we *can* deduce this further property in the special situation considered in Theorem 10.

11. COROLLARY. Let $M \subset \mathbb{R}^3$ be a compact convex surface with $K > 0$ everywhere. Then M is unbendable.

PROOF. Let $\alpha: [0, 1] \times M \rightarrow \mathbb{R}^3$ be any bending of the inclusion map $i: M \rightarrow \mathbb{R}^3$. Then all $\bar{\alpha}(t)(M)$ have $K > 0$ everywhere, so all $\bar{\alpha}(t)(M)$ are infinitesimally rigid, by Theorem 10. So the variation vector field Z_t of α at time t is trivial. Then by Lemma 5, the bending α is trivial. ♦

In this corollary, the case $K \geq 0$ eluded us, but we aren't going to worry very much about it, because we are now going to prove a much better result anyway, the famous theorem of Cohn-Vossen that any convex surface is unwarpable. This result is the uniqueness part of Weyl's Problem, mentioned in the previous chapter; the present proof stems from the work of Herglotz.

12. THEOREM (COHN-VOSSEN). If $M \subset \mathbb{R}^3$ is a compact convex surface, then M is unwarpable.

PROOF. As in the proof of Theorem 11, for simplicity we first consider the case where $K > 0$ everywhere. So we consider two imbeddings $f, \bar{f}: M \rightarrow \mathbb{R}^3$ with $f^*\langle \cdot, \cdot \rangle = \bar{f}^*\langle \cdot, \cdot \rangle$, such that the curvature $K = \bar{K}$ for this metric is > 0 everywhere. Let N, \bar{N} be the inward pointing normals, for the convex surfaces $f(M)$ and $\bar{f}(M)$, and orient these surfaces so that N and \bar{N} are the normals determined by the orientations. We can assume that M has an orientation which makes both maps $f: M \rightarrow f(M)$ and $\bar{f}: M \rightarrow \bar{f}(M)$ orientation preserving (by composing \bar{f} with a reflection if necessary). For each $p \in M$ we have two subspaces $df(M_p), d\bar{f}(M_p) \subset \mathbb{R}^3$, which are just $f_*(M_p)$ and $\bar{f}_*(M_p)$ moved over to the origin. So we can consider

$$\iota = d(f \circ \bar{f}^{-1}): d\bar{f}(M_p) \rightarrow df(M_p).$$

The magic 1-form which we want to consider is

$$\omega = (f \times N) \cdot (\iota \circ d\bar{N}).$$

Figuring out $d\omega$ will be quite a bit harder than in the previous theorem. First we will get an expression for ω in terms of moving frames. We choose a moving frame X_1, X_2 on M which is orthonormal for $f^*\langle \cdot, \cdot \rangle = \bar{f}^*\langle \cdot, \cdot \rangle$, and let θ^1, θ^2 and $\omega_1^2 = -\omega_2^1$ be its dual forms and connection forms. We can consider (f_*X_1, f_*X_2, N) and $(\bar{f}_*X_1, \bar{f}_*X_2, \bar{N})$ as adapted orthonormal moving frames on $f(M)$ and $\bar{f}(M)$; let ψ_1^3, ψ_2^3 be f^* of the corresponding forms on $f(M)$, and define $\bar{\psi}_1^3, \bar{\psi}_2^3$ similarly. Then for X tangent to M we have

$$\begin{aligned} d\bar{N}(X) &= \bar{\psi}_1^3(X) \cdot d\bar{f}(X_1) + \bar{\psi}_2^3(X) \cdot d\bar{f}(X_2) \\ (1) \quad &\Downarrow \\ \iota \circ d\bar{N}(X) &= \bar{\psi}_1^3(X) \cdot df(X_1) + \bar{\psi}_2^3(X) \cdot df(X_2). \end{aligned}$$

We will also express $f(p)$ as a linear combination

$$(2) \quad f(p) = y_1(p) \cdot df(X_1(p)) + y_2(p) \cdot df(X_2(p)) + y_3(p) \cdot N(p),$$

where, in particular,

$$(3) \quad y_3 = f \cdot N = -h.$$

Then for $X \in M_p$ we have

$$\begin{aligned}
 \omega(X) &= [f(p) \times N(p)] \cdot [\bar{\psi}_3^1(X) \cdot df(X_1) + \bar{\psi}_3^2(X) \cdot df(X_2)] && \text{by (1)} \\
 &= [y_1(p) \cdot df(X_1) \times N(p) + y_2(p) \cdot df(X_2) \times N(p)] \\
 &\quad \cdot [\bar{\psi}_3^1(X) \cdot df(X_1) + \bar{\psi}_3^2(X) \cdot df(X_2)] && \text{by (2)} \\
 &= y_1(p) \cdot \bar{\psi}_3^2(X) - y_2(p) \cdot \bar{\psi}_3^1(X),
 \end{aligned}$$

and consequently

$$(4) \quad \omega = -y_1 \bar{\psi}_2^3 + y_2 \bar{\psi}_1^3.$$

Now equation (2) implies that for $X \in M_p$ we have

$$\begin{aligned}
 df(X) &= dy_1(X) \cdot df(X_1(p)) + y_1(p) \nabla'_{f_* X} f_* X_1 + \dots \\
 &= dy_1(X) \cdot df(X_1(p)) + y_1(p) \omega_1^2(X) \cdot df(X_2(p)) \\
 &\quad + y_1(p) \psi_1^3(X) N(p) + \dots \\
 &= [dy_1(X) + y_2(p) \omega_2^1(X) + y_3(p) \psi_3^1(X)] df(X_1) + \dots.
 \end{aligned}$$

But also

$$df(X) = \theta^1(X) \cdot df(X_1) + \theta^2(X) \cdot df(X_2).$$

Hence we have

$$\begin{aligned}
 (5) \quad dy_1 &= \theta^1 + y_2 \omega_1^2 + y_3 \psi_1^3 \\
 dy_2 &= \theta^2 + y_1 \omega_2^1 + y_3 \psi_2^3.
 \end{aligned}$$

Now we can compute

$$\begin{aligned}
 d\omega &= d(-y_1 \bar{\psi}_2^3 + y_2 \bar{\psi}_1^3) && \text{by (4)} \\
 &= -(\theta^1 + y_2 \omega_1^2 + y_3 \psi_1^3) \wedge \bar{\psi}_2^3 + y_1 (\bar{\psi}_1^3 \wedge \omega_2^1) \\
 &\quad + (\theta^2 + y_1 \omega_2^1 + y_3 \psi_2^3) \wedge \bar{\psi}_1^3 - y_2 (\bar{\psi}_2^3 \wedge \omega_1^2) \\
 &\quad \text{by (5) and the structural equations} \\
 &= -\theta^1 \wedge \bar{\psi}_2^3 + \theta^2 \wedge \bar{\psi}_1^3 - y_3 (\psi_1^3 \wedge \bar{\psi}_2^3 - \psi_2^3 \wedge \bar{\psi}_1^3) \\
 &= -\{(\bar{l}_{11} + \bar{l}_{22}) + y_3 (l_{11} \bar{l}_{22} + \bar{l}_{11} l_{22} - 2l_{12} \bar{l}_{12})\} dA,
 \end{aligned}$$

where

$$l_{ij} = \Pi_f(X_i, X_j), \quad \bar{l}_{ij} = \Pi_{\bar{f}}(X_i, X_j), \quad dA = \theta^1 \wedge \theta^2.$$

Now one has to observe that

$$\begin{aligned} l_{11}\bar{l}_{22} - 2l_{12}\bar{l}_{12} + l_{11}\bar{l}_{12} &= (l_{11}l_{22} - l_{12}^2) + (\bar{l}_{11}\bar{l}_{22} - \bar{l}_{12}^2) \\ &\quad - \det \begin{pmatrix} \bar{l}_{11} - l_{11} & \bar{l}_{12} - l_{12} \\ \bar{l}_{12} - l_{12} & \bar{l}_{22} - l_{22} \end{pmatrix} \\ &= 2K - \det(d\bar{N} - dN), \end{aligned}$$

where we now regard dN and $d\bar{N}$ as maps $dN, d\bar{N}: M_p \rightarrow M_p$. We obtain finally

$$d\omega = -\{2\bar{H} - h(2K - \det(d\bar{N} - dN))\} dA.$$

So for our compact M we have

$$(6) \quad 2 \int_M \bar{H} dA - 2 \int_M hK dA = - \int_M h \det(d\bar{N} - dN) dA.$$

Using formula (V), we obtain the *Herglotz integral formula*:

$$(7) \quad 2 \int_M \bar{H} - H dA = - \int_M h \det(d\bar{N} - dN) dA.$$

[Note that formula (V) also follows from (6) by taking $f = \bar{f}$.] Now we need an algebraic

13. LEMMA. Let A and B be two self-adjoint linear transformations on \mathbb{R}^2 which are positive semi-definite (i.e., have eigenvalues ≥ 0). Suppose that $\det A = \det B$. Then

$$\det(A - B) \leq 0.$$

Moreover, if A and B are positive definite, then equality holds only if $A = B$; and if A and B are positive semi-definite, then equality holds only if A and B are proportional.

PROOF. Consider A and B as symmetric matrices, and suppose first that A is positive definite. Since A is self-adjoint, there is an orthogonal matrix P , with transpose P^t , satisfying

$$PAP^t = PAP^{-1} = \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix}, \quad \lambda_1, \lambda_2 > 0.$$

If we set

$$Q = CP, \quad C = \begin{pmatrix} \frac{1}{\sqrt{\lambda_1}} & 0 \\ 0 & \frac{1}{\sqrt{\lambda_2}} \end{pmatrix},$$

then

$$(a) \quad Q A Q^t = C P A P^t C = I.$$

Now consider $Q B Q^t$. It is also symmetric, so there is an orthogonal R with

$$(b) \quad (R Q) B (R Q)^t = R (Q B Q^t) R^t = \begin{pmatrix} \mu_1 & 0 \\ 0 & \mu_2 \end{pmatrix}, \quad \mu_1, \mu_2 > 0.$$

Moreover, equation (a) gives

$$(c) \quad (R Q) A (R Q)^t = R (Q A Q^t) R^{-1} = I.$$

[We have simply reproved the well-known result that two positive definite quadratic forms can be simultaneously diagonalized.] So for $S = R Q$ we have

$$\begin{aligned} (\det S)^2 \det B &= \mu_1 \mu_2 && \text{by (b),} \\ (\det S)^2 \det A &= 1 && \text{by (c).} \end{aligned}$$

If $\det A = \det B$, then

$$\mu_1 \mu_2 = 1.$$

Moreover,

$$(\det S)^2 \det(A - B) = \det \begin{pmatrix} 1 - \mu_1 & 0 \\ 0 & 1 - \mu_2 \end{pmatrix} = 2 - (\mu_1 + \mu_2).$$

Since for $x > 0$ we always have

$$x + \frac{1}{x} \geq 2, \quad \text{with equality only if } x = 1,$$

it follows that

$$2 - (\mu_1 + \mu_2) \leq 0,$$

with equality only if $\mu_1 = \mu_2 = 1 \implies A = B$.

Now suppose that A and B are positive semi-definite, with $A \neq 0$, say. We can now obtain Q with

$$(a') \quad Q A Q^t = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix},$$

and R with

$$(b') \quad (R Q) B (R Q)^t = \begin{pmatrix} \mu_1 & 0 \\ 0 & \mu_2 \end{pmatrix} \quad \mu_1, \mu_2 \geq 0, \quad \mu_1 \mu_2 = 0.$$

As before, we also have

$$(c') \quad (RQ)A(RQ)^t = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}.$$

So for $S = RQ$ we have

$$(\det S)^2 \det(A - B) = \det \begin{pmatrix} 1 - \mu_1 & 0 \\ 0 & -\mu_2 \end{pmatrix} = -\mu_2 + \mu_1\mu_2 = -\mu_2.$$

Thus $\det(A - B) \leq 0$, with equality only if $\mu_2 = 0 \implies B = \mu_1 \cdot A$. **Q.E.D.**

Applying the Lemma to the positive definite maps $dN, d\bar{N}: M_p \rightarrow M_p$, with the same determinant $K(p)$, we conclude from equation (7) that

$$\int_M \bar{H} dA - \int_M H dA \geq 0.$$

But we can interchange f and \bar{f} in this inequality to obtain

$$\int_M H dA - \int_M \bar{H} dA \geq 0.$$

Hence

$$\int_M H dA = \int_M \bar{H} dA.$$

Then equation (7) gives

$$(*) \quad \int_M h \det(d\bar{N} - dN) dA = 0.$$

Now $(*)$ implies that $\det(d\bar{N} - dN) = 0$ everywhere. Then Lemma 13 implies that $d\bar{N} = dN$ everywhere. So the fundamental theorem of surface theory implies that f and \bar{f} differ by a Euclidean motion.

Now we consider the case $K \geq 0$. We can still obtain $(*)$ and thus conclude that $\det(d\bar{N} - dN) = 0$ everywhere. We have to show that $d\bar{N}(p) = dN(p)$ for points p with $K(p) = 0$, and it is only necessary to consider points p with $K = 0$ in a whole neighborhood of p . If $f(p)$ and $\bar{f}(p)$ are both planar points, there is nothing to prove. So suppose that $f(p)$, say, is a parabolic point. Then, as in the previous proof, the point $f(p)$ is on some line segment $\Gamma \subset f(M)$, whose endpoints Q_1, Q_2 are in the closure of the set where $K > 0$. Let $\bar{\Gamma} \subset \bar{f}(M)$

be the image of Γ under the isometry $\bar{f} \circ f^{-1}: f(M) \rightarrow \bar{f}(M)$. Then $\bar{\Gamma}$ is a geodesic in $\bar{f}(M)$. Now Γ is also an asymptotic curve, $\Pi(X, X) = 0$ for tangent vectors X pointing along Γ . The last part of Lemma 13 then shows that we must have $\bar{\Pi}(Y, Y) = 0$ for tangent vectors Y pointing along $\bar{\Gamma}$. So $\bar{\Gamma}$ has normal curvature $\bar{\kappa}_n = 0$; since $\bar{\Gamma}$ has geodesic curvature $\bar{\kappa}_g = 0$, it follows that $\bar{\Gamma}$ has curvature $\bar{\kappa} = \sqrt{\bar{\kappa}_n^2 + \bar{\kappa}_g^2} = 0$. Hence $\bar{\Gamma}$ is also a straight line segment, with endpoints \bar{Q}_1, \bar{Q}_2 , say. Lemma 5-5 says that the non-zero principal curvature k along Γ is of the form

$$k(s) = \frac{1}{As + B},$$

where $k(s)$ is the value of k at the point on Γ at distance s from $f(p)$. In particular, k cannot approach zero at Q_1 or Q_2 , so Q_1 and Q_2 are not planar points. Since Q_1, Q_2 are in the closure of the set where $K > 0$ we have $dN(Q_i) = d\bar{N}(\bar{Q}_i)$, so \bar{Q}_1, \bar{Q}_2 are also not planar points. So by Corollary 5-6, $\bar{f}(p)$ is not a planar point. Thus the non-zero principal curvature \bar{k} along $\bar{\Gamma}$ is of the form

$$\bar{k}(s) = \frac{1}{\bar{A}s + \bar{B}},$$

where s now measures the distance from $\bar{f}(p)$. But since $dN(Q_i) = d\bar{N}(\bar{Q}_i)$, we have $k(Q_i) = \bar{k}(\bar{Q}_i)$. It follows that $A = \bar{A}$ and $B = \bar{B}$. Hence $d\bar{N}(p) = dN(p)$. ♦

For later use, we insert here a form of the Herglotz integral formula for compact surfaces-with-boundary.

14. LEMMA. Let M be a compact oriented surface with boundary ∂M , and let $f, \bar{f}: M \rightarrow \mathbb{R}^3$ be immersions with $f^*\langle \cdot, \cdot \rangle = \bar{f}^*\langle \cdot, \cdot \rangle$. Let $N, \bar{N}: M \rightarrow \mathbb{R}^3$ be the normals determined by the orientation, let dA be the volume form on $(M, f^*\langle \cdot, \cdot \rangle)$, and let ds be the volume form on ∂M . For $p \in \partial M$ let $\mathbf{t}(p), \mathbf{u}(p)$ be the first two vectors of the Darboux frame at $f(p)$ for the curve $f(\partial M)$ on $f(M)$; we regard \mathbf{t} and \mathbf{u} as elements of \mathbb{R}^3 , as usual. Let κ_n and τ_g be the normal curvature and geodesic torsion for this curve, and let $\bar{\kappa}_n$ and $\bar{\tau}_g$ be the corresponding quantities for the curve $\bar{f}(\partial M)$ on $\bar{f}(M)$. Then

$$\begin{aligned} \int_{\partial M} (\bar{\tau}_g - \tau_g) \langle f, \mathbf{t} \rangle + (\kappa_n - \bar{\kappa}_n) \langle f, \mathbf{u} \rangle ds \\ = \int_M h \det(d\bar{N} - dN) dA + 2 \int_M \bar{H} - H dA. \end{aligned}$$

PROOF. We consider the 1-form

$$\omega = (f \times N) \cdot (\iota \circ d\bar{N})$$

of the previous proof, for which we have

$$(1) \quad d\omega = -\{2\bar{H} - h(2K - \det(d\bar{N} - dN))\} dA.$$

If \mathbf{s} is the unit tangent vector of the curve ∂M on $(M, f^*\langle \cdot, \cdot \rangle)$, so that $df(\mathbf{s}) = \mathbf{t}$, then

$$dN(\mathbf{s}) = -\kappa_n \mathbf{t} - \tau_g \mathbf{u},$$

by definition of κ_n and τ_g . Similarly,

$$(\iota \circ d\bar{N})(\mathbf{s}) = -\bar{\kappa}_n \mathbf{t} - \bar{\tau}_g \mathbf{u}.$$

Therefore

$$(2) \quad \begin{aligned} \omega(\mathbf{s}) &= f \cdot N \times (\iota \circ d\bar{N})(\mathbf{s}) = f \cdot N \times [-\bar{\kappa}_n \mathbf{t} - \bar{\tau}_g \mathbf{u}] \\ &= f \cdot (\bar{\tau}_g \mathbf{t} - \bar{\kappa}_n \mathbf{u}) \\ &= \bar{\tau}_g \langle f, \mathbf{t} \rangle - \bar{\kappa}_n \langle f, \mathbf{u} \rangle. \end{aligned}$$

Substituting (1) and (2) into Stokes' Theorem,

$$\int_{\partial M} \omega = \int_M d\omega,$$

we obtain

$$(3) \quad \begin{aligned} \int_{\partial M} \bar{\tau}_g \langle f, \mathbf{t} \rangle - \bar{\kappa}_n \langle f, \mathbf{u} \rangle ds &= -2 \int_M \bar{H} dA + 2 \int_M hK dA \\ &\quad + \int_M h \det(d\bar{N} - dN) dA. \end{aligned}$$

We cannot use formula (V) for $\int_M hk dA$, since M is not compact. But choosing $\bar{f} = f$ in (3) we obtain

$$\int_{\partial M} \tau_g \langle f, \mathbf{t} \rangle - \kappa_n \langle f, \mathbf{u} \rangle ds = -2 \int_M H dA + 2 \int_M hK dA.$$

Substituting this into (3), we obtain the desired result. \blacklozenge

The proofs of Theorems 10 and 12 have a formal correspondence which is even more complete than their superficial resemblance. Indeed, suppose that the two imbeddings f, \bar{f} of Theorem 12 are part of a variation α of f , with variation vector field Z . Then each $\bar{\alpha}(t)$ has a normal field N_t , and the integrand $h \det(d\bar{N}_t - dN)$ of the Herglotz integral formula can be expanded in powers of t ; the terms up to second order in t turn out to be exactly the integrand in Blaschke's integral formula.

More to the point, perhaps, is the fact that the proofs of Theorems 10 and 12 are equally mysterious. They depend on discovering 1-forms ω for which $d\omega = (\text{something interesting}) \cdot dA$; these 1-forms ω are suggested by the geometry in only the vaguest way, and one simply has to carry out the computations explicitly to see what $d\omega$ really is. In this connection, however, the following may be mentioned. The requirement that \bar{f} be an imbedding with the same metric as f is a system of partial differential equations (in 2 variables) for the components of \bar{f} . (The requirement that α be a bending of f is an even more complicated equation in 3 variables, and the basic aim of introducing infinitesimal bendings is to reduce the problem to one in only 2 variables. This "linearization" of the problem leads to a system of linear partial differential equations.) Theorems 10 and 12 may be regarded as uniqueness theorems for partial differential equations on M . As Stoker {1} points out, "the proofs of uniqueness theorems for boundary-value problems involving other partial differential equations also usually require the invention of special tricks and devices, above all if the problems are nonlinear, and such devices commonly involve integrals over the domains in question (e.g., energy integrals in problems having their origin in mathematical physics)."

This is perhaps an opportune moment to describe briefly the original, quite geometric, proofs of these rigidity results. Theorem 10 was first proved by Liebmann, and the crux of his proof was the following observation. Let Z be an infinitesimal bending of $M \subset \mathbb{R}^3$. Regarding each $Z(p)$ as an element of \mathbb{R}^3 , we obtain a surface $Z = \{Z(p) : p \in M\} \subset \mathbb{R}^3$. Of course, this may not really be an immersed surface; indeed we hope to prove that it contains only one point when M is compact with $K > 0$. Liebmann showed that at points $p \in M$ where $p \mapsto Z(p)$ is an immersion, the curvature of Z is < 0 at $Z(p)$ when the curvature of M is > 0 at p . This immediately shows that $p \mapsto Z(p)$ cannot be an immersion everywhere when M is compact with $K > 0$, since Z would then be a compact surface with $K < 0$. Liebmann showed that even when Z has singularities, it is nevertheless true that if Z is not a point, then Z has the character of a surface of negative curvature, in the sense that no point q of Z has a support plane (a plane containing q and all points of Z on one side of it);

this property again contradicts the compactness of Z . Since Liebmann's proof involves the investigation of singularities, it is hardly surprising that it works only in the analytic case.

Cohn-Vossen's proof was also originally restricted to the analytic case, and is quite similar to the proof of Hopf's Theorem (Theorem 9-33) on surfaces of constant mean curvature, which was obviously inspired by it. Given $M, \bar{M} \subset \mathbb{R}^3$, with normals ν and $\bar{\nu}$, and an isometry $\phi: M \rightarrow \bar{M}$, we call $p \in M$ a "congruence point" if $\phi^*(\bar{\Pi}(\phi(p))) = \Pi(p)$. If ϕ is not the restriction of a Euclidean motion, then by analyticity the congruence points are isolated. At all other points p , Lemma 13 shows that

$$\det[\phi^*(\bar{\Pi}(\phi(p))) - \Pi(p)] < 0,$$

where the bilinear functions $\Pi(p)$ and $\phi^*(\bar{\Pi}(\phi(p)))$ are regarded as linear transformations on M_p by means of the metric on M_p . It follows that the linear transformation corresponding to the difference $\phi^*(\bar{\Pi}(\phi(p))) - \Pi(p)$ has two eigenspaces, one with a positive eigenvalue, and one with a negative eigenvalue. By picking the one with the positive eigenvalue, say, we obtain a 1-dimensional distribution defined everywhere on M except at the congruence points. At each congruence point we can define the index of the distribution, and the sum of these indices is 2 if M is homeomorphic to S^2 (Theorem 4-20). On the other hand, Cohn-Vossen showed that if M has positive curvature, then the index would have to be negative. The Bibliography will guide the interested reader to descriptions of Cohn-Vossen's argument, as well as alternative arguments and refinements introduced later. We merely mention here that the assumption of analyticity can be dropped by using appropriate results about partial differential equations, and that the whole argument can be formalized to yield an "index method", which has been successfully used in studying certain questions in surface theory; it is one of the few methods which has never yet been generalized to higher dimensions.

We will now return to the use of integral formulas, and prove a result similar to Cohn-Vossen's, which although not strictly speaking a rigidity theorem, nevertheless seems to belong in this chapter since it is the uniqueness part of Minkowski's Problem (page 156). The original proof was based on the general "Brunn-Minkowski inequality" for the "mixed volumes" of convex sets (see Bonnesen-Fenchel [1]). The present proof, obviously inspired by Herglotz' proof of Cohn-Vossen's theorem, is due to Chern.

15. THEOREM (MINKOWSKI). Let M be a compact surface with $K > 0$ everywhere, and let $f, \bar{f}: M \rightarrow \mathbb{R}^3$ be two isometric imbeddings with $N = \bar{N}$.

Then f and \bar{f} differ by a translation. (Alternatively stated, if two compact convex surfaces in \mathbb{R}^3 with everywhere positive curvatures have the same curvatures at points where the normals are parallel, then one surface is a translate of the other.)

PROOF. Since $K > 0$, the maps $N, \bar{N}: M \rightarrow S^2 \subset \mathbb{R}^3$ are diffeomorphisms, so we can consider the imbeddings

$$\begin{aligned} g &= f \circ N^{-1}: S^2 \rightarrow \mathbb{R}^3 \\ \bar{g} &= \bar{f} \circ \bar{N}^{-1}: S^2 \rightarrow \mathbb{R}^3. \end{aligned}$$

These imbeddings have the property that $p \in S^2$ is normal to the tangent plane of $g(S^2)$ at $g(p)$, and similarly for \bar{g} . Thus the normal maps $\xi, \bar{\xi}: S^2 \rightarrow \mathbb{R}^3$ for g and \bar{g} are both the identity map $\text{id}: S^2 \rightarrow S^2$. Since $N = \bar{N}$, and f, \bar{f} are isometries by hypothesis, the maps g, \bar{g} induce the same metric on S^2 . It clearly suffices to show that g and \bar{g} differ by a translation.

Consider the 1-form

$$\omega = (g \times \bar{g}) \cdot d\bar{g}$$

on S^2 . We have

$$\begin{aligned} (1) \quad d\omega &= (dg \times \bar{g}) \cdot d\bar{g} + (g \times d\bar{g}) \cdot d\bar{g} \\ &= -\bar{g} \cdot (dg \times d\bar{g}) + g \cdot (d\bar{g} \times d\bar{g}). \end{aligned}$$

To calculate $d\omega$ explicitly we consider a positively oriented moving frame on S^2 which is orthonormal for the usual metric on S^2 . If we move the vectors $X_i(p)$ over to $g(p)$, then the translated vectors, $Y_i(g(p))$, will be tangent to $g(S^2)$ at $g(p)$, since $\xi(p) = p$. Thus we obtain an orthonormal moving frame Y_1, Y_2 on $g(S^2)$. Let θ^1, θ^2 be the dual forms for Y_1, Y_2 and let ψ_β^α be the connection forms for the moving frame (Y_1, Y_2, ν) on $g(S^2)$, where ν is the unit normal field on $g(S^2)$. Define $\bar{\theta}^i$ and $\bar{\psi}_\beta^\alpha$ similarly, using \bar{g} . If we set

$$\eta^i = g^* \theta^i, \quad \bar{\eta}^i = \bar{g}^* \bar{\theta}^i,$$

then for X tangent to S^2 we have

$$\begin{aligned} (2) \quad dg(X) &= \eta^1(X) \cdot Y_1 + \eta^2(X) \cdot Y_2 = \eta^1(X) \cdot X_1 + \eta^2(X) \cdot X_2, \\ d\bar{g}(X) &= \bar{\eta}^1(X) \cdot X_1 + \bar{\eta}^2(X) \cdot X_2, \end{aligned}$$

where the X_i and Y_i are now regarded as \mathbb{R}^3 -valued functions. It follows that we have

$$\begin{aligned} dg \times d\bar{g} &= (\eta^1 \wedge \bar{\eta}^2 - \eta^2 \wedge \bar{\eta}^1) \cdot \text{id}, \\ d\bar{g} \times d\bar{g} &= 2(\bar{\eta}^1 \wedge \bar{\eta}^2) \cdot \text{id}, \end{aligned}$$

so that (1) becomes

$$(3) \quad d\omega = \bar{h}(\eta^1 \wedge \bar{\eta}^2 - \eta^2 \wedge \bar{\eta}^1) - 2h(\bar{\eta}^1 \wedge \bar{\eta}^2),$$

where h and \bar{h} are the support functions of g and \bar{g} , respectively.

Now we have to relate the forms $\eta^i, \bar{\eta}^i$ to the dual forms for the moving frame X_1, X_2 on S^2 . On $g(S^2)$ we have

$$\psi_i^3 = \sum_j l_{ij} \theta^j$$

where $l_{ij} = \Pi(Y_i, Y_j)$; hence

$$g^* \psi_i^3 = \sum_j (l_{ij} \circ g) \cdot \eta^j.$$

But

$$\begin{aligned} g^* \psi_i^3(X) &= \psi_i^3(g_* X) = -\psi_3^i(g_* X) \\ &= \langle -v_* g_* X, Y_i \rangle \\ &= \langle -d(v \circ g)(X), Y_i \rangle \\ &= \langle -d\xi(X), Y_i \rangle \\ &= \langle -X, Y_i \rangle = \langle -X, X_i \rangle. \end{aligned}$$

So if ζ^1, ζ^2 are the dual forms for X_1, X_2 , so that $\zeta^1 \wedge \zeta^2 = dA$, the volume element of S^2 , then

$$\zeta^i = - \sum_j (l_{ij} \circ g) \cdot \eta^j.$$

If λ is the 2×2 matrix of functions on S^2 defined by

$$\lambda(p) = (l_{ij}(g(p)))^{-1},$$

then

$$\eta^i = - \sum_j \lambda_{ij} \cdot \zeta^j.$$

Similarly,

$$\bar{\eta}^i = - \sum_j \bar{\lambda}_{ij} \zeta^j,$$

where $\bar{\lambda}$ is the inverse of the matrix $(\bar{l}_{ij} \circ \bar{g})$. Since

$$\det(l_{ij} \circ g) = \det(\bar{l}_{ij} \circ \bar{g}) = K,$$

where K is the curvature for the metrics $g^*\langle \ , \ \rangle$ and $\bar{g}^*\langle \ , \ \rangle$ on S^2 , we likewise have

$$\det(\lambda_{ij}) = \det(\bar{\lambda}_{ij}) = K^{-1}.$$

Now we have

$$\bar{\eta}^1 \wedge \bar{\eta}^2 = (\det \bar{\lambda}) \zeta^1 \wedge \zeta^2 = K^{-1} dA$$

and

$$\eta^1 \wedge \bar{\eta}^2 - \eta^2 \wedge \bar{\eta}^1 = (\lambda_{11} \bar{\lambda}_{22} + \bar{\lambda}_{11} \lambda_{22} - 2\lambda_{12} \bar{\lambda}_{12}) dA.$$

Calculating as in the preceding proof, we see that

$$\eta^1 \wedge \bar{\eta}^2 - \eta^2 \wedge \bar{\eta}^1 = [2K^{-1} - \det((d\bar{v})^{-1} - (dv)^{-1})] dA.$$

So equation (3) becomes

$$d\omega = -\{\bar{h} \det((d\bar{v})^{-1} - (dv)^{-1}) + 2K^{-1}(\bar{h} - h)\} dA.$$

Hence

$$\int_{S^2} \bar{h} \det((d\bar{v})^{-1} - (dv)^{-1}) dA = - \int_{S^2} 2K^{-1}(\bar{h} - h) dA.$$

Then Lemma 13 shows that the left side is ≤ 0 , so that the right side is also ≤ 0 . By symmetry we conclude that the right side is 0, and then by Lemma 13 again that in fact $dv = d\bar{v}$. Thus there is a Euclidean motion A such that $\bar{g} = A \circ g$ and $\bar{v} = A_* v$. The latter implies that A is a translation. ♦

Sometimes this result is expressed in a way that looks quite different: Let $M, \bar{M} \subset \mathbb{R}^3$ be compact surfaces with $K, \bar{K} > 0$ everywhere, and let $\phi: M \rightarrow \bar{M}$ be a map such that $\bar{K}(\phi(p)) = K(p)$ and such that ϕ preserves the third fundamental forms. Then ϕ is the restriction of a Euclidean motion. To see the equivalence of this statement and Theorem 15, just note that by Proposition 2-7, the normal maps of M and \bar{M} are congruent, so after rotating \bar{M} suitably we have two surfaces satisfying the hypothesis of Theorem 15.

Unlike the last few results, Theorem 15 is not true if we allow $K \geq 0$; a counterexample is shown below. Notice, however, that the components of the

set where $K \neq 0$ on one surface do differ from the corresponding components in the other surface by a translation. It is not hard to see that this is always the case, and that Theorem 15 remains true if the set where $K = 0$ is nowhere dense. (For the alternative statement of the theorem surely the only reasonable situation is that in which N is one-one.)

In our next result, the condition $K > 0$ is more crucial, for we are going to consider the sum

$$\frac{1}{k_1} + \frac{1}{k_2} = \frac{2H}{K}$$

of the reciprocals of the principal curvatures; the reciprocals are classically called the “radii of principal curvature”. After constructing a proof of Minkowski’s Theorem by means of integral formulas, Chern then succeeded in constructing a similar proof for the following result, which is actually older than any yet considered.

16. THEOREM (CHRISTOFFEL). Let M be a compact surface with $K > 0$ everywhere, and let $f, \bar{f}: M \rightarrow \mathbb{R}^3$ be two imbeddings with $N = \bar{N}$ such that

$$\frac{1}{k_1} + \frac{1}{k_2} = \frac{1}{\bar{k}_1} + \frac{1}{\bar{k}_2},$$

where the functions k_i and \bar{k}_i on M are the principal curvatures at the corresponding points of $f(M)$ and $\bar{f}(M)$, respectively. Then f and \bar{f} differ by a translation.

PROOF. We introduce the imbeddings $g, \bar{g}: S^2 \rightarrow \mathbb{R}^3$ of the previous proof, and we will use all the notation and formulas from that proof. In addition, we note that for the normal map $\xi = \text{id}$ of g we have, of course,

$$d\xi(X) = X = \zeta^1(X) \cdot X_1 + \zeta^2(X) \cdot X_2,$$

from which it follows that

$$\begin{aligned} (1) \quad d\xi \times dg &= (\zeta^1 \wedge \eta^2 - \zeta^2 \wedge \eta^1) \cdot \xi \\ &= -(\lambda_{22} + \lambda_{11})\xi dA \\ &= -(k_1^{-1} + k_2^{-1})\xi dA. \end{aligned}$$

Similarly, since $\xi = \bar{\xi}$, we have

$$(2) \quad d\xi \times d\bar{g} = -(\bar{k}_1^{-1} + \bar{k}_2^{-1})\xi dA.$$

Consider first the 1-form

$$\omega_1 = (g \times \xi) \cdot d\bar{g}.$$

We have

$$\begin{aligned} d\omega_1 &= (dg \times \xi) \cdot d\bar{g} + (g \times d\xi) \cdot d\bar{g} \\ &= -\xi \cdot (dg \times d\bar{g}) + g \cdot (d\xi \times d\bar{g}) \\ &= -\xi \cdot (dg \times d\bar{g}) - (\bar{k}_1^{-1} + \bar{k}_2^{-1})g \cdot \xi dA \quad \text{by (2)} \\ &= -\xi \cdot (dg \times d\bar{g}) + h(\bar{k}_1^{-1} + \bar{k}_2^{-1}) dA. \end{aligned}$$

Similarly, for the 1-form

$$\omega_2 = (g \times \xi) \cdot dg$$

we have

$$d\omega_2 = -\xi \cdot (dg \times dg) + h(k_1^{-1} + k_2^{-1}) dA.$$

Since $k_1^{-1} + k_2^{-1} = \bar{k}_1^{-1} + \bar{k}_2^{-1}$, we obtain the integral formula

$$(3) \quad \int_{S^2} \xi \cdot (dg \times d\bar{g}) - \xi \cdot (dg \times dg) dA = 0.$$

By interchanging the roles of g and \bar{g} we also obtain

$$(4) \quad \int_{S^2} \xi \cdot (d\bar{g} \times dg) - \xi \cdot (d\bar{g} \times d\bar{g}) dA = 0.$$

Adding (3) and (4) we obtain an integral formula

$$(*) \quad \int_{S^2} I dA = 0.$$

Now we have

$$\begin{aligned} \xi \cdot (dg \times d\bar{g}) - \xi \cdot (dg \times dg) &= (\eta^1 \wedge \bar{\eta}^2 - \eta^2 \wedge \bar{\eta}^1) \xi \cdot \xi - 2(\eta^1 \wedge \eta^2) \xi \cdot \xi \\ &= (\lambda_{11}\bar{\lambda}_{22} + \bar{\lambda}_{11}\lambda_{22} - 2\lambda_{12}\bar{\lambda}_{12} - 2(\lambda_{11}\lambda_{22} - \lambda_{12}^2)) dA, \\ \xi \cdot (d\bar{g} \times dg) - \xi \cdot (d\bar{g} \times d\bar{g}) &= (\bar{\lambda}_{11}\lambda_{22} + \lambda_{11}\bar{\lambda}_{22} - 2\lambda_{12}\bar{\lambda}_{12} - 2(\bar{\lambda}_{11}\bar{\lambda}_{22} - \bar{\lambda}_{12}^2)) dA. \end{aligned}$$

So the integrand I in $(*)$ is

$$\begin{aligned} I &= 2(\lambda_{11}\bar{\lambda}_{22} + \bar{\lambda}_{11}\lambda_{22} - 2\lambda_{12}\bar{\lambda}_{12}) - 2(\lambda_{11}\lambda_{22} - \lambda_{12}^2) - 2(\bar{\lambda}_{11}\bar{\lambda}_{22} - \bar{\lambda}_{12}^2) dA \\ &= -2[(\bar{\lambda}_{11} - \lambda_{11})(\bar{\lambda}_{22} - \lambda_{22}) - (\bar{\lambda}_{12} - \lambda_{12})^2] dA. \end{aligned}$$

Since $\lambda_{11} + \lambda_{22} = \bar{\lambda}_{11} + \bar{\lambda}_{22}$ by hypothesis, we can write

$$\begin{aligned} I &= -2[(\lambda_{22} - \bar{\lambda}_{22})(\bar{\lambda}_{22} - \lambda_{22}) - (\bar{\lambda}_{12} - \lambda_{12})^2] dA \\ &= 2[(\bar{\lambda}_{22} - \lambda_{22})^2 + (\bar{\lambda}_{12} - \lambda_{12})^2] dA. \end{aligned}$$

So the integrand I in $(*)$ is everywhere ≥ 0 . Hence it must be everywhere $= 0$. Hence $\lambda_{ij} = \bar{\lambda}_{ij}$, implying that $dv = d\bar{v}$, and the proof is complete, as before. ♦

In Christoffel's time the radii of principal curvature were regarded as the fundamental entities (which is pretty awkward when $K = 0$), so Theorem 16 was the natural result to try to prove. Nowadays, of course, the result looks rather weird and we would like to formulate it for $H = \frac{1}{2}(k_1 + k_2)$ instead. Oddly enough, this more reasonable looking problem hasn't been solved. The pair of surfaces pictured on page 203 give a counterexample of sorts, but I do not know of any counterexample which is strictly convex. This same pair of surfaces illustrates the need for the final hypothesis appearing in the following result along these lines, which replaces the conditions on the normal maps by one on the imbeddings themselves (as some sort of compensation for the stringency of this hypothesis, notice that no hypothesis on K is required).

17. THEOREM (HOPF AND VOSS). Let M be a compact surface, and let $f, \bar{f}: M \rightarrow \mathbb{R}^3$ be two imbeddings with $H = \bar{H}$ such that $\bar{f}(p) - f(p)$ is always parallel to a fixed vector $v \in \mathbb{R}^3$. Suppose, moreover, that $f(M)$ and $\bar{f}(M)$ do not contain a portion of a cylinder with generators parallel to v . Then f and \bar{f} differ by a translation in the direction of v .

PROOF. Write

$$\bar{f} = f + \alpha \cdot v$$

for some function α on M . For any $X_1, X_2 \in M_p$ we have

$$\begin{aligned} d\bar{f}(X_1) \times d\bar{f}(X_2) &= [df(X_1) + d\alpha(X_1) \cdot v] \times [df(X_2) + d\alpha(X_2) \cdot v] \\ &= df(X_1) \times df(X_2) \\ &\quad + [d\alpha(X_1) \cdot v \times df(X_2) - d\alpha(X_2) \cdot v \times df(X_1)]. \end{aligned}$$

So

$$d\bar{f} \times d\bar{f} = df \times df + 2(d\alpha \cdot v \times df).$$

By (I), this is equivalent to

$$(1) \quad \bar{N} d\bar{A} = N dA + (d\alpha \cdot v \times df).$$

Consider the 1-form

$$\omega_1 = (\alpha \cdot v \times n) \cdot df.$$

We have

$$\begin{aligned} (2) \quad d\omega_1 &= (d\alpha \cdot v \times N) \cdot df + (\alpha \cdot v \times dN) \cdot df \\ &= -N \cdot (d\alpha \cdot v \times df) + \alpha \cdot v \cdot (dN \times df) \\ &= dA - (N \cdot \bar{N}) d\bar{A} + 2\alpha H(v \cdot N) dA \quad \text{by (1) and (I).} \end{aligned}$$

Similarly, for the 1-form

$$\omega_2 = (\alpha \cdot v \times \bar{N}) \cdot df,$$

we have

$$\begin{aligned}
 (3) \quad d\omega_2 &= (d\alpha \cdot v \times \bar{N}) \cdot df + (\alpha \cdot v \times d\bar{N}) \cdot df \\
 &= (d\alpha \cdot v \times \bar{N}) \cdot df + (\alpha \cdot v \times d\bar{N}) \cdot d\bar{f}, \\
 &\quad \text{since } d\bar{f} = df + d\alpha \cdot v \\
 &= -\bar{N} \cdot (d\alpha \cdot v \times df) + \alpha \cdot v \cdot (d\bar{N} \times d\bar{f}) \\
 &= N \cdot \bar{N} dA - d\bar{A} + 2\alpha \bar{H}(v \cdot \bar{N}) d\bar{A} && \text{by (I) and (I)} \\
 &= N \cdot \bar{N} dA - d\bar{A} + 2\alpha \bar{H}(v \cdot N) dA && \text{by (I).}
 \end{aligned}$$

From (2) and (3) we derive the integral formula

$$2 \int_M \alpha (\bar{H} - H)(v \cdot N) dA = \int_M (1 - N \cdot \bar{N})(dA + d\bar{A}).$$

Since $H = \bar{H}$, we thus have

$$\int_M (1 - N \cdot \bar{N})(dA + d\bar{A}) = 0.$$

But $N \cdot \bar{N} \leq 1$, so we must have $N \cdot \bar{N} = 1$ everywhere, and hence $N = \bar{N}$ everywhere. We will use this to show that α is constant.

For simplicity assume that v points along the z -axis. The final hypothesis implies that $N(p)$ has non-zero z -component for all points p in a dense open set. If p is such a point, then $f(M)$ and $\bar{f}(M)$ can be represented near p as the graphs of two functions, g and \bar{g} , say. Then the normals are given by

$$\frac{(g_1, g_2, -1)}{\sqrt{1 + g_1^2 + g_2^2}} \quad \text{and} \quad \frac{(\bar{g}_1, \bar{g}_2, -1)}{\sqrt{1 + \bar{g}_1^2 + \bar{g}_2^2}}.$$

Since these normals are everywhere equal, we must have $g_i = \bar{g}_i$, so α is constant in a neighborhood of p . ♦

Before returning to rigidity theory proper, we will take this opportunity to mention that Minkowski's Theorem and Christoffel's Theorem have generalizations to compact hypersurfaces $M \subset \mathbb{R}^{n+1}$ with all principal curvatures

$k_1, \dots, k_n > 0$. For each $i = 1, \dots, n$ we can consider the elementary symmetric polynomial

$$P_i = \sigma_i \left(\frac{1}{k_1}, \dots, \frac{1}{k_n} \right).$$

If M and \bar{M} are two such hypersurfaces, and for some i the functions P_i and \bar{P}_i agree at points of M and \bar{M} where the normals are parallel, then one hypersurface is a translate of the other. A proof may be found in Chern [1]. (Our proofs of Theorems 15 and 16 are taken from that paper, and are pretty representative of the sort of argument which is used. In fact, the proof of Theorem 15 is a special case of Chern's proof for all $i > 1$, while the proof of Theorem 16 is a special case of Chern's proof for $i = 1$, which needs a separate argument. Chern remarks that that distinction is significant, since the case $i = 1$ involves linear partial differential equations, while the case $i > 1$ involves non-linear ones.)

Another remark is necessary to put Theorem 16 on an equal footing with Theorems 12 and 15. The latter two results give the uniqueness of imbeddings whose existence was discussed in Chapter 11 (Weyl's Problem and Minkowski's Problem). The corresponding existence result for Christoffel's Problem is much more involved, for there are complicated relations which must be satisfied by a given function on S^2 in order for it to be $1/k_1 + 1/k_2$ for some imbedded surface. Many incomplete treatments of this problem have been given, and the correct necessary and sufficient conditions (in all dimensions) were discovered only in 1967 by Firey [1]. One could also seek the conditions on a function in order that it be P_i ($1 < i < n$) for some convex hypersurface, but this problem is perhaps hopelessly complicated.

Finally, we want to point out that the higher dimensional generalization of the Minkowski and Christoffel theorems can also be expressed as follows: Let $M, \bar{M} \subset \mathbb{R}^{n+1}$ be compact hypersurfaces with all principal curvatures > 0 , and let $\phi: M \rightarrow \bar{M}$ be a map such that $\bar{P}_i(\phi(p)) = P_i(p)$ and such that ϕ preserves the third fundamental forms. Then ϕ is the restriction of a Euclidean motion. The argument is just the same as on page 203, using Problem 7-18 in place of Proposition 2-7. In this connection it is interesting that É. Cartan [2] raised the possibility of studying surfaces by means of their *second* fundamental form, rather than their first. For example, he showed that if \mathbf{II} is positive definite, then the curvature of (M, \mathbf{II}) can be written in terms of the ordinary principal curvatures and their derivatives. Grove [1] used integral formulas to prove that a diffeomorphism of compact convex surfaces which preserves \mathbf{II} and the Gaussian curvature $K = k_1 k_2$ is the restriction of a Euclidean motion, and Walden [1] used the index method to prove the same result if either $k_1 + k_2$ or $k_1^{-1} + k_2^{-1}$ is

preserved (as well as if $k_1^2 + k_2^2$ or $k_1^{-2} + k_2^{-2}$ is preserved). On the other hand, it is perfectly conceivable that a diffeomorphism of compact convex surfaces is the restriction of a Euclidean motion if it merely preserves \mathbf{II} , and perhaps the surfaces need not even be convex. In higher dimensions, the only result is that of Gardner [1], proved using integral formulas, which generalizes Grove's result to the case where \mathbf{II} and $k_1 \cdots k_n$ are preserved.

All our rigidity results have required the hypothesis of convexity, so it is only natural to wonder what happens in the case of non-convex surfaces. There is a standard example, illustrated below, of two compact rotation surfaces which

are isometric but not congruent. To be sure, this example is rather unsatisfying, since it is merely C^∞ , and cannot be modified to be analytic. Moreover, the surface consists of two parts which are individually kept rigid, but which are glued together in two different ways along a plane curve where $K = 0$. Finally, this example is merely a reflection of the fact that the plane has infinitesimal bendings which vanish outside a compact set. It could have been obtained by starting with a surface containing a portion of a plane, finding an infinitesimal

bending Z which vanishes outside the planar region, and then mapping $p + Z(p)$ to $p - Z(p)$, which is an isometry, by Lemma 7, but not the restriction of a Euclidean motion, by Lemma 8. We can at least show that there is no bending connecting our two non-congruent isometric C^∞ surfaces. In fact, there is not

even a bending taking the small region A of positive curvature pictured below to its corresponding region A' in the other surface, the region A' being simply

the mirror image of A . To prove this, we simply recall that any surface of positive curvature has a natural orientation, which has to be preserved during the bending.

Long before such C^∞ trickiness was in vogue, Cohn-Vossen [1] had investigated infinitesimally bendable rotation surfaces by quite different methods, and he found C^∞ rotation surfaces with non-trivial C^2 infinitesimal bendings. Afterwards, Rembs [1] managed to obtain an example where the rotation surface is analytic; but the infinitesimal bending is still only C^2 (a point which is by no means made clear in the paper). Applying Lemmas 7 and 8 in this case we merely obtain two C^2 isometric non-congruent surfaces, which seems a lot worse than C^∞ ; but at least this example is not a bald-faced trick like the previous one. Since the example is interesting, but nevertheless rather disappointing, it has been relegated to an Addendum.

It seems that at present it is simply unknown whether every analytic compact surface is unwarpable. *A fortiori* it is unknown whether every analytic compact surface is unbendable; it certainly seems likely that even C^∞ compact surfaces are unbendable.

There is only one crumb of comfort which we can offer in this dismal situation. It is known that a torus of revolution is unwarpable. Such a torus M has

the property that

$$\int_{M^+} K \, dA = 4\pi,$$

where $M^+ = \{p \in M : K(p) > 0\}$; the closure $C(M^+)$ of M^+ is a compact surface with boundary such that $\partial C(M^+)$ is the union of plane curves along which the tangent space of M is constant. Suppose that $\phi: M \rightarrow \bar{M}$ is an isometry. Then also

$$\int_{\bar{M}^+} K dA = 4\pi,$$

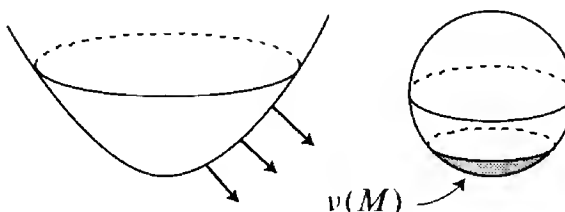

so it follows from Theorem 6-16 that $C(\bar{M}^+)$ is a compact surface of the same sort as $C(M^+)$. Now apply Lemma 14 to $f =$ inclusion map of $C(M^+)$ and $\tilde{f} = \phi: C(M^+) \rightarrow C(\bar{M}^+)$. The terms $\tau_g, \kappa_n, \bar{\tau}_g, \bar{\kappa}_n$ are all 0, since the normal is constant along each component of $\partial C(M^+)$ and $\partial C(\bar{M}^+)$. So we have simply

$$0 = \int_{C(M^+)} h \det(d\bar{N} - dN) dA + 2 \int_{C(M^+)} \bar{H} - H dA,$$

the same equality which we used in the proof of Theorem 12. Then the same argument which was used in this proof shows that $\phi: C(M^+) \rightarrow C(\bar{M}^+)$ is the restriction of a Euclidean motion.

This already shows that any *analytic* surface of minimal total absolute curvature is unwarpageable in the class of *analytic* surfaces, a result originally due to Alexandrov [4]. A proof that ϕ is also the restriction of a Euclidean motion on the part of the surface with $K < 0$ has been given by Nirenberg [2]. The proof, which involves a discussion of hyperbolic equations, requires some additional, rather unsatisfactory, hypotheses, but these hypotheses are satisfied at least in the special case of a torus of revolution.

We can also ask about the rigidity of complete convex non-compact surfaces. It is not hard to see (compare the pictures on pg. IV.84) that the normal map v of such a surface M always lies in a hemisphere, so that

$$\int_M K dA \leq 2\pi.$$

The first result on complete convex non-compact surfaces was the surprising theorem of Olowjanischnikow [1] that M is *warpageable* if $\int_M K dA < \pi$. Olowjanischnikow's proof uses the methods of the Russian school of differential

geometry, which was briefly discussed in Chapter 11. As we have already mentioned, these methods, though intricate and difficult, allow one to prove certain results for surfaces which are merely continuous. For example, Pogorelov {1} has proved Cohn-Vossen's theorem for arbitrary convex surfaces: if M and \bar{M} are the boundaries of compact convex sets (with non-empty interiors) in \mathbb{R}^3 , and $\phi: M \rightarrow \bar{M}$ is a map which preserves lengths of curves, then ϕ is a congruence. Similarly, Olowjanischnikow's result holds whenever M is the boundary of a closed non-compact convex set (with non-empty interior) in \mathbb{R}^3 . Pogorelov {2; pg. 114} also showed that any surface isometric to such a surface M may be joined to M by a continuous bending. To my knowledge, no one has ever provided simpler proofs of these results when the surfaces considered are C^∞ .

When our complete convex surface M has

$$\int_M K dA = 2\pi,$$

it is unwarpable. The proof of this is due to Pogorelov [2]. We have already seen that such surfaces, although unwarpable, and hence unbendable, may nevertheless be infinitesimally bendable; and I think that this is the only known instance of such a phenomenon.

As opposed to the complete convex surfaces, consider what happens when we delete a set with non-empty interior from a convex surface. Is it bendable,

or warpable, or infinitesimally bendable? The promptings of intuition seem to vary from person to person, and historically there was considerable confusion on the question. We claim first of all that any open set $U \subset S^2$ whose closure \bar{U} is contained in an open hemisphere of S^2 is warpable. For this purpose we consider the rotation surface M_a of constant curvature 1 given on pg. III.163, with $a > 1$. Locally there is an isometry $S^2 \rightarrow M_a$ taking the tangent vectors $(0, 1, 0)$ and $(0, 0, 1)$ at $(1, 0, 0) \in S^2$ to the tangent vectors $(0, 1, 0)$ and $(0, 0, 1)$ at $(a, 0, 0) \in M_a$. If a is sufficiently close to 1, then this isometry can be extended to cover $\bar{U} \subset$ the hemisphere $\{p \in S^2 : p^1 > 0\}$. The image of U is contained

in the open set $V \subset M_a$ which is obtained by deleting the profile curve of M_a in the left half (x, z) -plane, as well as a neighborhood of the top and bottom boundary curves. We also claim that this open set V is bendable. To prove this

we consider all the rotation surfaces $M_{a'}$ for a' close to a . Then there will be an isometry $f_{a'}: V \rightarrow M_{a'}$ which takes the tangent vectors $(0, 1, 0)$ and $(0, 0, 1)$ at $(a, 0, 0) \in M_a$ to the tangent vectors $(0, 1, 0)$ and $(0, 0, 1)$ at $(a', 0, 0) \in M_{a'}$. The 1-parameter family of isometries $\{f_{a'}\}$ gives us the bending.

The warpability of U was noted in a paper by Liebmann [1] in 1900, which also offered up a proof that U is not warpable if it contains a closed hemisphere. Fifteen years later, Blaschke [1] observed that the proof, “as simple as this assertion may appear”, was incorrect. In 1919 Liebmann [2] showed that in fact the sphere minus any disc, no matter how small, is bendable. He did this by specifically constructing the bending, using other classical examples of open surfaces of constant curvature 1. A physically intuitive argument, involving soap bubbles, is given in Hilbert and Cohn-Vossen [1]. Liebmann was then willing to conjecture that any convex surface with $K > 0$ everywhere is bendable after a small disc is removed. The infinitesimal bendability of such surfaces was proved by Cohn-Vossen [2] in 1927, and bendability was proven by Hellwig [1] in 1955; both proofs require facts about partial differential equations, with more difficult theorems required for bendability. (This question has also been treated by the Russian school; see Pogorelov [2; pg. 104].)

It should be noted that the bendability of a convex surface M with a set $A \subset M$ removed does not necessarily imply the bendability of $M - B$ for $A \subset B$. For conceivably the bending of $M - A$ might always be constant on

$M - B$! But at least we do not have to worry about this anomaly if M is analytic, with $K > 0$ everywhere. For it then follows from the results of Chapter 11 that all warpings of $M - A$ are also analytic.

We can also ask what happens when we delete even smaller sets from a convex surface M . Hilbert and Cohn-Vossen [1] claim that the sphere minus any segment of a great circle is bendable, but I have never seen a reference to such a result. I am almost certain that nothing similar is known when the sphere is replaced by an arbitrary convex surface M . As recently as 1971, Green and Wu [1] showed that if only finitely many points are removed from a compact surface M with $K \geq 0$ everywhere, then the resulting surface $M' = M - \{p_1, \dots, p_k\}$ is unwarpable. On the other hand, Pogorelov [1] had already shown that if $k \geq 2$, then M' is warpable as an immersion: there is an isometric immersion of M' which is not an imbedding (in fact, there are infinitely many inequivalent isometric immersions). In one special case this is easy to see: Take M' to be $S^2 - \{p_1, p_2\}$, where p_1 and p_2 are the north and south poles, and consider the surface of revolution M_a on pg. III.163 with $a = 1/2$; it is not hard to compute

that the area of M_a is just $1/2$ the area of S^2 . Then there will be an isometry of a closed hemisphere of $S^2 - \{p_1, p_2\}$ onto M_a which takes the two semi-circles on the boundary onto the same curve in M_a , namely its profile curve in the left half (x, z) -plane. By using a similar map on the other hemisphere of $S^2 - \{p_1, p_2\}$ we obtain a local isometry $S^2 - \{p_1, p_2\} \rightarrow M_a$ which is a double covering.

To end this discussion of holey surfaces we mention one more indication of the abysmal state of our ignorance: It is not known whether the standard torus minus a disc is bendable, or even warpable.

We now turn our attention to purely local results about rigidity, where further surprises are in store for us. We will begin by examining some of the classical results along this line, partly to give an idea of the sort of questions which used to be investigated, and partly because some of these questions throw great light on the geometric aspects of the Darboux equation.

Consider a surface $M \subset \mathbb{R}^3$ and an arclength parameterized curve $\tilde{c}: [a, b] \rightarrow M$. Given another arclength parameterized curve $c: [a, b] \rightarrow \mathbb{R}^3$, we ask whether there is a neighborhood \tilde{V} of $\tilde{c}([a, b])$ in M and an isometry $\phi: \tilde{V} \rightarrow V$ of \tilde{V} onto a surface $V \subset \mathbb{R}^3$ such that $\phi \circ \tilde{c} = c$. In other words, we want to know to what extent a curve \tilde{c} on M can be changed in a local warping. We might as well assume that M is the image of an isometric immersion $\tilde{f}: (U, (g_{ij})) \rightarrow \mathbb{R}^3$, where $U \subset \mathbb{R}^2$ is an open set containing $[a, b] \times \{0\}$, and $\tilde{c}(x) = \tilde{f}(x, 0)$ for $x \in [a, b]$. On $[a, b] \times \{0\}$ we can compute the geodesic curvature $\tilde{\kappa}_g$ of \tilde{c} . If the isometry ϕ exists, then the geodesic curvature κ_g of c on V must be the same as $\tilde{\kappa}_g$. On the other hand, if c is a curve on any surface V whatsoever, then its geodesic curvature κ_g on V always has absolute value less than or equal to its curvature κ (which is a known function). Thus we see that the isometry ϕ cannot exist unless

$$|\tilde{\kappa}_g| \leq \kappa.$$

Consider the case where we have the strict inequality $|\tilde{\kappa}_g(x)| < \kappa(x)$ for all x . If the surface V exists, and $\nu(c(x))$ is its normal at $c(x)$, then equation (9) on pg. III.190 shows that we must have

$$\tilde{\kappa}_g = \kappa_g = \kappa \cdot \sin \phi,$$

where ϕ is the angle from the principal normal $\mathbf{n}(x)$ of c to $\nu(c(x))$. This equation determines two possible choices for ϕ , and hence two possible choices

for the tangent space $V_{c(x)}$. Consider either of the two possible continuous choices of $V_{c(x)}$ along c . We claim that we can find V with this choice of $V_{c(x)}$.

We will look for V as the image of an isometric immersion $f: U \rightarrow \mathbb{R}^3$ with $c(x) = f(x, 0)$. By changing our coordinate system on U , we can assume that

$$g_{12} = 0, \quad g_{22} = 1; \quad \text{and} \quad g_{11} = 1 \quad \text{along } [a, b] \times \{0\}.$$

We easily compute that in this case the curve $x \mapsto (x, 0)$ has geodesic curvature

$$(1) \quad \tilde{\kappa}_g(x) = -\frac{1}{2}(g_{11})_y.$$

Now the vector $\mathbf{v} = (0, 1)_{(x, 0)} \in U_{(x, 0)}$ is a unit vector perpendicular to $(1, 0)_{(x, 0)} \in U_{(x, 0)}$. Obviously we want the vector

$$f_*(\mathbf{v}) = \chi(x), \quad \text{say}$$

to be a unit vector in the known vector space $V_{c(x)}$, perpendicular to the known tangent vector $c'(x)$. Thus $\chi(x)$ is determined along $[a, b] \times \{0\}$. For the values of $\chi(x)$ so determined we have

$$(2) \quad \begin{cases} \langle \chi(x), c'(x) \rangle = 0 \\ \langle \chi(x), \chi(x) \rangle = 1 \\ \langle \chi(x), c''(x) \rangle = \kappa(x) \cdot \langle \chi(x), \mathbf{n}(x) \rangle \\ \quad = \kappa(x) \cdot \sin \phi \\ \quad = \tilde{\kappa}_g(x) = -\frac{1}{2}(g_{11})_y, \quad \text{by (1).} \end{cases}$$

Now we can use the arguments in the proof of Theorem 11-9. We have the map f defined on $[a, b] \times \{0\}$ by $f(x, 0) = c(x)$, and we want to extend f to a neighborhood of $[a, b] \times \{0\}$ in U . The submanifold $[a, b] \times \{0\}$ isn't necessarily of the form $\exp_0(V_1)$, but that is irrelevant, because we have already determined χ

satisfying (2), which are just the equations (2') on page 151. Moreover, χ is linearly independent of f_x, f_{xx} on $[a, b] \times \{0\}$, as required. Thus we can solve equation (*) in the proof of Theorem 11-9 with the initial conditions $f(x, 0) = c(x)$ and $q(x, 0) = \chi(x)$.

This argument requires that the original surface M and the curves \tilde{c}, c be analytic, in order to apply the Cauchy-Kowalewski theorem. But analyticity is not needed if M has curvature $K < 0$, for in this case the system involved is hyperbolic, as we mentioned on page 154.

For other purposes, it is also important that we examine the classical treatment of this problem, by means of the Darboux equation. We continue to use the special coordinate system on U , with $g_{12} = 0$ and $g_{22} = 1$; and $g_{11} = 1$ along $[a, b] \times \{0\}$. We would like to find $f = (u, v, w)$ by using the three components of the equations

$$\begin{aligned} f(x, 0) &= c(x) \\ f_y(x, 0) &= \chi(x) \end{aligned}$$

as the initial conditions for the solutions u, v, w of the Darboux equation. Unfortunately that simple procedure won't work, since, as we have already seen, there is not that much arbitrariness permitted in the choice of u, v, w . What we have to do is first find a solution w of the Darboux equation with

$$(3) \quad w(x, 0) = c^3(x), \quad w_y(x, 0) = \chi^3(x),$$

and then choose u and v so that we at least have

$$(4) \quad \begin{aligned} u(0, 0) &= c^1(0), & u_x(0, 0) &= c^{1'}(0), & u_y(0, 0) &= \chi^1(0) \\ v(0, 0) &= c^2(0), & v_x(0, 0) &= c^{2'}(0), & v_y(0, 0) &= \chi^2(0), \end{aligned}$$

and so that $f = (u, v, w)$ is an isometry, and consequently satisfies

$$(5) \quad \left\{ \begin{array}{l} g_{11} = \langle f_x, f_x \rangle = u_x \cdot u_x + v_x \cdot v_x + w_x \cdot w_x \\ 0 = \langle f_x, f_y \rangle = u_x \cdot u_y + v_x \cdot v_y + w_x \cdot w_y \\ 1 = \langle f_y, f_y \rangle = u_y \cdot u_y + v_y \cdot v_y + w_y \cdot w_y \\ \quad \quad \quad \Downarrow \text{(as in the proof of Theorem 11-9)} \\ -\frac{1}{2}(g_{11})_y = \langle f_{xx}, f_y \rangle = u_{xx} \cdot u_y + v_{xx} \cdot v_y + w_{xx} \cdot w_y. \end{array} \right.$$

We claim that u and v will automatically have the desired initial conditions on $[a, b] \times \{0\}$. To see this, consider the \mathbb{R}^2 -valued functions

$$\begin{aligned} \alpha(x) &= (c^{1'}(x), c^{2'}(x)) \\ \beta(x) &= (\chi^1(x), \chi^2(x)). \end{aligned}$$

By substituting equations (3) into equations (2), we find that α and β satisfy

$$\begin{aligned} \text{(i)} \quad & \langle \alpha, \beta \rangle = -w_y(x, 0) \cdot w_x(x, 0) \\ \text{(ii)} \quad & \langle \beta, \beta \rangle = 1 - w_y(x, 0) \cdot w_y(x, 0) \\ \text{(iii)} \quad & \langle \alpha', \beta \rangle = -\frac{1}{2}(g_{11})_y - w_y(x, 0) \cdot w_{xx}(x, 0), \end{aligned}$$

while we also have

$$\text{(iv)} \quad \langle \alpha, \alpha \rangle = 1 - w_x(x, 0) \cdot w_x(x, 0) = g_{11}(x, 0) - w_x(x, 0) \cdot w_x(x, 0).$$

Simple arguments (Problem 1) show that the solution of the system of equations (i)–(iv) is completely determined once $\alpha(0), \beta(0)$ are known. But equations (5) show that

$$\begin{aligned} & (u_x(x, 0), v_x(x, 0)) \\ & (u_y(x, 0), v_y(x, 0)) \end{aligned}$$

satisfy this system, while equations (4) insure that

$$\begin{aligned} \alpha(0) &= (u_x(0, 0), v_x(0, 0)) \\ \beta(0) &= (u_y(0, 0), v_y(0, 0)). \end{aligned}$$

It follows that for all $x \in [a, b]$ we have

$$\begin{aligned} (c^1(x), c^2(x)) &= \alpha(x) = (u_x(x, 0), v_x(x, 0)) \\ &\implies (c^1(x), c^2(x)) = (u(x, 0), v(x, 0)) \quad \text{by (4)} \\ (\chi^1(x), \chi^2(x)) &= \beta(x) = (u_y(x, 0), v_y(x, 0)). \end{aligned}$$

Thus u and v will indeed have the initial conditions which we would like, and $f = (u, v, w)$ will be the required isometric imbedding.

We have already noted in the previous chapter that the Darboux equation is hyperbolic when $K < 0$, so we do not need the Cauchy-Kowalewski theorem in that case. In this case there is still one problem remaining, however, for in order to solve the Darboux equations for w with the initial conditions (3), we need to know that the interval $[a, b]$ of the x -axis is free for these initial conditions. Here is the place where the geometry links up beautifully with the analysis. To begin with, suppose we have an isometric immersion $f = (u, v, w): (U, (g_{ij})) \rightarrow \mathbb{R}^3$, and a curve γ in U . Then w is a solution of the Darboux equation, and we

would like to know when γ is free for the initial conditions which we obtain by restricting w to γ . Recall that for the second order PDE

$$F(x, y, u, p, q, r, s, t) = 0,$$

this means (c.f. (I-4) on page 84) that

$$\frac{\partial F}{\partial r} \cdot (v^1)^2 + \frac{\partial F}{\partial s} \cdot v^1 v^2 + \frac{\partial F}{\partial t} \cdot (v^2)^2 \neq 0 \quad \text{at } \gamma(t),$$

where (v^1, v^2) is the normal to γ at t . Since (v^1, v^2) is proportional to $(-\gamma_2', \gamma_1')$, this means that

$$\frac{\partial F}{\partial r} \cdot (\gamma_2')^2 - \frac{\partial F}{\partial s} \cdot \gamma_1' \gamma_2' + \frac{\partial F}{\partial t} \cdot (\gamma_1')^2 \neq 0.$$

Consider the Darboux equation in the form (*) on page 143. Our condition becomes

$$(6) \quad (w_{22} - \Gamma_{22}^1 w_1 - \Gamma_{22}^2 w_2)(\gamma_2')^2 + 2(w_{12} - \Gamma_{12}^1 w_1 - \Gamma_{12}^2 w_2)\gamma_1' \gamma_2' \\ + (w_{11} - \Gamma_{11}^1 w_1 - \Gamma_{11}^2 w_2)(\gamma_1')^2 \neq 0,$$

which by equation (1) on page 143 becomes

$$0 \neq N^3[l_{22}(\gamma_2')^2 + 2l_{12}\gamma_1'\gamma_2' + l_{11}(\gamma_1')^2] \\ = N^3\Pi_f(\gamma', \gamma').$$

Thus the curve γ is free for the initial conditions determined by w if and only if the curve $f \circ \gamma$ on $f(U)$ is nowhere asymptotic, and the tangent plane for $f(U)$ is nowhere vertical along γ . On the other hand, γ is characteristic for these initial conditions if and only if $f \circ \gamma$ is an asymptotic curve, except perhaps at points where the tangent plane of $f(U)$ is vertical. These conditions have the paradoxical feature customarily associated with the Darboux equation: the condition on a single component w of f is stated in terms of the whole map f . When we are merely given initial conditions along a curve, rather than a solution, we simply write out equation (6) as stated. In the situation we are considering, our initial curve is just the interval $[a, b]$ of the x -axis, so that $\gamma_1' = 1$ and

$\gamma_2' = 0$, and we compute that in our special coordinate system on U we have

$$\left. \begin{aligned} [11, 2] &= -\frac{1}{2}(g_{11})_y \\ [12, 1] &= [21, 1] = \frac{1}{2}(g_{11})_y \\ \text{other } [ij, k] &= 0 \end{aligned} \right\} \quad \text{along the } x\text{-axis,}$$

and then

$$\left. \begin{aligned} \Gamma_{12}^1 &= \Gamma_{21}^1 = \frac{1}{2}(g_{11})_y \\ \Gamma_{11}^2 &= -\frac{1}{2}(g_{11})_y \\ \text{other } \Gamma_{ij}^k &= 0 \end{aligned} \right\} \quad \text{along the } x\text{-axis.}$$

Then equation (6) becomes

$$(6') \quad w_{11} + \frac{1}{2}(g_{11})_y w_2 \neq 0, \quad \text{or} \quad (c^3)'' - \tilde{\kappa}_g \chi^3 \neq 0.$$

Now in our situation, χ is not a multiple of c'' . Simply by rotating everything, we can then insure that $(c^3)'' - \tilde{\kappa}_g \chi^3 \neq 0$ on $[a, b] \times \{0\}$. Thus we really can solve the Darboux equation and obtain an isometry $\phi: \tilde{V} \rightarrow V$ with $\phi \circ \tilde{c} = c$ (suitably rotated). Naturally we can then obtain a new isometry ϕ' with $\phi' \circ \tilde{c} = c$.

Things work out quite differently when we try to find an isometry $\phi: \tilde{V} \rightarrow V$ with $\phi \circ \tilde{c} = c$ in the case where $\tilde{\kappa}_g(x) = \kappa(x)$ for all x . If ϕ exists, then we must have $\kappa_g = \tilde{\kappa}_g = \kappa$, so c must be an asymptotic curve on V , which means that V must have $K \leq 0$ along c so M must have $K \leq 0$ along \tilde{c} . We will actually assume $K < 0$, so that the Darboux equations are hyperbolic. We first suppose that $\kappa(x) > 0$ for all x . Then the Beltrami-Enneper Theorem (Theorem 4-7) shows that the torsion τ of c must satisfy

$$\tau(x) = \pm \sqrt{-K(c(x))} = \pm \sqrt{-K(\tilde{c}(x))}.$$

Thus there is, up to Euclidean motions, only one possibility for c . If we are given this curve c , and $\phi: \tilde{V} \rightarrow V$ exists, then $V_{c(x)}$ must be the osculating plane of c at x , so our choice for $\chi(x) = f_y(x, 0)$ must be the principal normal $\mathbf{n}(x)$ of c at $\chi(x)$. In this situation we have $c'' = \kappa \mathbf{n} = \kappa \chi = \tilde{\kappa}_g \chi$, so equation (6') is *not* true; our initial curve is characteristic for the initial conditions. Fortunately, we have complete information about this situation, since we are dealing with a Monge-Ampère equation. Along the x -axis our Darboux equation (from page 143) is

$$[w_{11} + \frac{1}{2}(g_{11})_y w_2] \cdot w_{22} - [w_{12} - \frac{1}{2}(g_{11})_y w_1]^2 = K(1 - w_1^2 - w_2^2).$$

As we pointed out at the end of section 8 of Chapter 10, there is no hope of solving for w_{22} along the x -axis unless we also have

$$(7) \quad -[w_{12} - \tfrac{1}{2}(g_{11})_y w_1]^2 = K(1 - w_1^2 - w_2^2)$$

along the x -axis. Moreover, if this equation does hold, then we can choose w_{22} arbitrarily, and there will be a solution with these initial conditions. We claim that equation (7) holds as a consequence of our choice of c . For,

$$\begin{aligned} [w_{12} - \tfrac{1}{2}(g_{11})_y w_1]^2 &= \{(\mathbf{n}' + \kappa c')^3\}^2 && \text{[the 3 denotes third component]} \\ &= \{(-\kappa c' + \tau \mathbf{b} + \kappa c')^3\}^2 && \text{by Serret-Frenet} \\ &= \{(\tau \mathbf{b})^3\}^2 = \tau^2 (\mathbf{b}^3)^2 \\ &= -K(\mathbf{b}^3)^2, \end{aligned}$$

so we just have to show that

$$(\mathbf{b}^3)^2 = 1 - w_1^2 - w_2^2 = 1 - \{(c')^3\}^2 - \{\mathbf{n}^3\}^2.$$

This is elementary: we have

$$e_3 = \langle e_3, c' \rangle c' + \langle e_3, \mathbf{n} \rangle \mathbf{n} + \langle e_3, \mathbf{b} \rangle \mathbf{b},$$

and when we take the inner product with e_3 we get

$$1 = \{(c')^3\}^2 + \{\mathbf{n}^3\}^2 + \{\mathbf{b}^3\}^2,$$

as desired.

Thus, when c is a curve with $\kappa = \tilde{\kappa}_g$ and $\tau^2 = -K$, we can find infinitely many isometries $\phi: \tilde{V} \rightarrow V$ with $\phi \circ \tilde{c} = c$; all the surfaces V are tangent to each other along c . In particular, if \tilde{c} is an asymptotic curve on M , with $K < 0$ along \tilde{c} , then we can take c to be \tilde{c} , and we see that a neighborhood of \tilde{c} can be continuously bent keeping \tilde{c} fixed; all surfaces in the bending are tangent to M along \tilde{c} . As opposed to this, if \tilde{c} satisfies $\tilde{\kappa}_g < \tilde{\kappa}$ everywhere, then there is only one other surface containing \tilde{c} which is isometric to a neighborhood of \tilde{c} in M , and it is nowhere tangent to M along \tilde{c} .

The case where $\kappa = \tilde{\kappa} = 0$ (both \tilde{c} and c are straight lines) is similar, except that now there is even complete leeway in the choice of the tangent space of V along c .

The discovery that asymptotic lines of a surface are precisely the curves along which the surface may be bent leads one to formulate all sorts of other questions.

For example, when is there an isometry $\phi: M \rightarrow \bar{M}$ which takes both families of asymptotic lines of M to asymptotic lines of \bar{M} ? It is easy to see that this happens essentially only when ϕ is the restriction of a Euclidean motion. In fact, if $f: U \rightarrow M$ is an imbedding for which the parameter lines are asymptotic curves, so that $l = n = 0$, and we define $\bar{f} = \phi \circ f$, then also $\bar{l} = \bar{n} = 0$. But we have, in addition,

$$ln - m^2 = \bar{l}\bar{n} - \bar{m}^2 \implies m = \pm\bar{m}.$$

If we restrict our attention to surfaces with $K < 0$, then we must have $m = \bar{m}$ or $m = -\bar{m}$ everywhere, and we can assume $m = \bar{m}$ by suitable choice of the normal. Hence ϕ is the restriction of a Euclidean motion.

Since this question turned out to be rather uninteresting, we modify it by investigating isometries $\phi: M \rightarrow \bar{M}$ which take the asymptotic curves of only one family of asymptotic lines on M to asymptotic lines on \bar{M} . Choose an orthonormal moving frame X_1, X_2 on M such that $\text{II}(X_1, X_1) = 0$, so that the integral curves of X_1 are the given family of asymptotic curves. Then we have

$$(1) \quad \begin{aligned} \psi_1^3 &= m\theta^2 \\ \psi_2^3 &= m\theta^1 + n\theta^2, \end{aligned}$$

where $0 = l = \text{II}(X_1, X_1)$ and $m = \text{II}(X_1, X_2)$ and $n = \text{II}(X_2, X_2)$. Let \bar{X}_1, \bar{X}_2 be the orthonormal moving frame $\bar{X}_i = \phi_* X_i$ on \bar{M} , and let barred forms (e.g., $\bar{\psi}_1^3$) actually denote ϕ^* of the corresponding forms on \bar{M} . Then $\bar{\theta}^i = \theta^i$ and $\bar{\omega}_2^1 = \omega_2^1$. Now $\bar{l} = \bar{\text{II}}(\bar{X}_1, \bar{X}_1) = 0$ by the hypothesis that our family of asymptotic curves is taken into asymptotic curves. Moreover,

$$ln - m^2 = \bar{l}\bar{n} - \bar{m}^2 \implies m = \pm\bar{m};$$

again we consider only the case $K < 0$ everywhere, so we might as well assume that $m = \bar{m}$, by suitable choice of the normals. Then we have

$$(2) \quad \begin{aligned} \bar{\psi}_1^3 &= m\theta^2 \\ \bar{\psi}_2^3 &= m\theta^1 + \bar{n}\theta^2. \end{aligned}$$

In particular,

$$\begin{aligned} \psi_1^3 = \bar{\psi}_1^3 &\implies d\psi_1^3 = d\bar{\psi}_1^3 \\ &\implies \omega_1^2 \wedge \psi_2^3 = \omega_1^2 \wedge \bar{\psi}_2^3 \quad \text{by Codazzi-Mainardi} \\ &\implies (n - \bar{n})\omega_1^2 \wedge \theta^2 = 0. \end{aligned}$$

Applying this to X_1, X_2 yields

$$(n - \bar{n}) \cdot \omega_1^2(X_1) = 0.$$

If $n = \bar{n}$ everywhere, then ϕ is a congruence. Assume that $n - \bar{n}$ is always $\neq 0$. Then $\omega_1^2(X_1) = 0 \implies \nabla_{X_1} X_1 = 0$, so the integral curves of X_1 are geodesics. Since they are also asymptotic curves, they must be straight lines; similarly their images, being both geodesics and asymptotic curves, are straight lines. In other words, this case involves a ruled surface being warped in such a way that the rulings remain straight.

[In general, it is easy to see that ruled surfaces can always be bent keeping their generators straight. In fact, suppose that our ruled surface is

$$f(s, t) = c(s) + t\delta(s), \quad |\delta| = 1 \implies \langle \delta, \delta' \rangle = 0.$$

Then

$$E = \langle c' + t\delta', c' + t\delta' \rangle = \langle c', c' \rangle + 2t\langle c', \delta' \rangle + t^2\langle \delta', \delta' \rangle$$

$$F = \langle c', \delta \rangle$$

$$G = 1.$$

Let $\bar{\delta}$ be any curve with

$$|\bar{\delta}| = 1, \quad |\bar{\delta}'| = |\delta'|.$$

In order for the surface

$$\bar{f}(s, t) = \bar{c}(s) + t\bar{\delta}(s)$$

to have the same metric as f , the curve \bar{c} must satisfy

$$|\bar{c}'| = |c'|$$

$$\langle \bar{c}', \bar{\delta}' \rangle = \langle c', \delta' \rangle$$

$$\langle \bar{c}', \bar{\delta} \rangle = \langle c, \delta \rangle,$$

which is always solvable for \bar{c}' . The curve $\bar{\delta}$ can have essentially any shape. For example, if $\delta' \neq 0$ everywhere (the rulings are always changing), then we could reparameterize so that $|\delta| = |\delta'| = 1$. Then all we require is $|\bar{\delta}| = |\bar{\delta}'| = 1$, so that $\bar{\delta}$ can trace out any regular curve in S^2 .]

Here is one final classical problem about bendings. When does a surface M have a bending $\alpha: [0, 1] \times M \rightarrow \mathbb{R}^3$ such that each $\bar{\alpha}(t)(M) \subset M$? One example that immediately comes to mind is a surface of revolution. Obviously any

surface isometric to a surface of revolution also has this property. (The question really has almost nothing to do with surfaces in \mathbb{R}^3 , and is essentially intrinsic.) We will show that “in general” these are the only such surfaces. What we actually assume is that the various curves $c_p(t) = \alpha(t, p)$ give a foliation of M . Since each $\bar{\alpha}(t)$ is an isometry, each curve c_p has constant geodesic curvature, for $\bar{\alpha}(t_1) \circ \bar{\alpha}(t_0)^{-1}$ is an isometry taking a neighborhood of $c(t_0)$ to a neighborhood of $c(t_1)$. Now for any curve c_p , consider its “geodesic parallels”, the set of

points at a fixed distance d along the geodesics perpendicular to c_p . Let q be

the point on the geodesic intersecting c_p orthogonally at p . Clearly $\alpha(t, q)$ is on the geodesic intersecting c_p orthogonally at $\alpha(t, p)$. Thus the geodesic parallels of c_p are the other curves c_q . Note that the geodesics perpendicular to c_p are also perpendicular to c_q (Problem I.9-28). Now take a coordinate system u, v such that the v -parameter curves lie along the curves c_p , while the u -parameter curves are the arclength parameterized geodesics perpendicular to all curves c_p . Then the metric has the form

$$du \otimes du + G dv \otimes dv.$$

A computation shows that the geodesic curvature of the v -parameter curve through $(u, 0)$ is

$$\kappa_u(v) = -\frac{1}{2} \frac{G_u(u, v)}{G(u, v)} = -\frac{1}{2} \frac{\partial \log G}{\partial u}(u, v).$$

But $\kappa_u(v)$ depends only on u . So $\log G$ is of the form $a(u) + b(v)$, and thus G is of the form

$$G(u, v) = A(u) \cdot B(v).$$

Letting v_1 be a function with

$$v_1' = \sqrt{B},$$

our metric takes the form

$$du \otimes du + A(u) dv_1 \otimes dv_1.$$

Comparing with formula (4) on pg. III.158, we see that M is isometric to a surface of revolution. It doesn't seem worthwhile refining these purely local considerations by trying to analyze in detail just what happens when some of the curves c_p degenerate to points, but it certainly would be nice if one could prove that a compact surface M admitting a bending into itself is (globally) isometric to a surface of revolution.

Just for the hell of it, we will also look at a couple of classical local results about infinitesimal bendings. Let $M \subset \mathbb{R}^3$ be a surface, and let $\alpha: [0, 1] \times M \rightarrow \mathbb{R}^3$ be any variation of the inclusion map $i: M \rightarrow \mathbb{R}^3$ whose variation vector field Z at $t = 0$ is an infinitesimal bending of M . Let X_1, X_2 be an orthonormal moving frame on M . Then

$$\left. \frac{d}{dt} \right|_{t=0} \langle \bar{\alpha}(t)_* X_i, \bar{\alpha}(t)_* X_j \rangle = \langle dZ(X_i), X_j \rangle + \langle X_i, dZ(X_j) \rangle$$

by the argument on pages 171–172; since Z is an infinitesimal bending we thus have

$$(1) \quad \left. \frac{d}{dt} \right|_{t=0} \langle \bar{\alpha}(t)_* X_i, \bar{\alpha}(t)_* X_j \rangle = 0.$$

On each surface $\bar{\alpha}(t)(M)$ we can define an orthonormal moving frame $X_1(t), X_2(t)$ by applying the Gram-Schmidt orthonormalization process to $\bar{\alpha}(t)_* X_1, \bar{\alpha}(t)_* X_2$. Let $\theta^i(t)$ be $\bar{\alpha}(t)^*$ of the dual forms for this moving frame, so that $\theta^i(0) = \theta^i$, the dual forms for X_1, X_2 . Equation (1) is easily seen to imply that

$$(2) \quad 0 = \left. \frac{d}{dt} \right|_{t=0} \theta^i(t) = \dot{\theta}^i, \quad \text{say.}$$

For each t we have unique forms $\omega_j^i(t)$ with

$$(3) \quad \begin{aligned} \omega_j^i(t) &= -\omega_i^j(t) \\ d\theta^i(t) &= -\sum_{j=1}^2 \omega_j^i(t) \wedge \theta^j(t). \end{aligned}$$

Letting $t = 0$, we see that $\omega_j^i(t) = \omega_j^i$, the connection forms for X_1, X_2 . Now differentiate (3) with respect to t . Since (Problem 2) we always have

$$(d\eta)^\cdot = d\dot{\eta}$$

for any 1-parameter family of forms $\eta(t)$, we obtain, using (2),

$$\begin{aligned}\dot{\omega}_j^i &= -\dot{\omega}_i^j \\ 0 &= d\dot{\theta}^i = (d\theta^i)^\cdot = -\sum_{j=1}^2 \dot{\omega}_j^i \wedge \theta^j - \sum_{j=1}^2 \omega_j^i \wedge \dot{\theta}^j \\ &= -\sum_{j=1}^2 \dot{\omega}_j^i \wedge \theta^j.\end{aligned}$$

It follows that $\dot{\omega}_2^1 = 0$. Now we differentiate the equation

$$d\omega_2^1(t) = K(t) \theta^1(t) \wedge \theta^2(t),$$

to obtain

$$0 = d\dot{\omega}_2^1 = (d\omega_2^1)^\cdot = \dot{K} \theta^1 \wedge \theta^2 + 0.$$

Thus we see that we always have

$$\dot{K} = 0.$$

It now seems a natural enough question to ask when we have $\dot{H} = 0$. The answer to this question is left to Problem 4.

Another question, especially interesting in view of Lemma 6, is to find those surfaces M which possess an infinitesimal bending Z that is everywhere *tangent* to M . Once again, surfaces of rotation are obvious examples. Moreover, one can easily show that if Z is an infinitesimal bending of M which is tangent to M , and $f: M \rightarrow \bar{M}$ is an isometry, then $\bar{Z} = f_*Z$ is an infinitesimal bending of \bar{M} .

Again we can show that “in general” these are the only such surfaces. Given a nowhere 0 infinitesimal bending Z tangent along M , we choose an immersion $f: U \rightarrow M$ such that the v -parameter curves lie along the integral curves of Z , and the u -parameter curves along the curves perpendicular to them. Then $I_f = f^*(\ , \)$ has the form

$$I_f = E du \otimes du + G dv \otimes dv.$$

By assumption, Z is always proportional to $\partial f / \partial v$, and it will be convenient to write Z as

$$Z = \frac{\lambda}{\sqrt{G}} \frac{\partial f}{\partial v} = \frac{\lambda}{\sqrt{G}} f_2.$$

Then the equations

$$0 = \langle Z_1, f_1 \rangle = \langle Z_2, f_2 \rangle, \quad 0 = \langle Z_1, f_2 \rangle + \langle Z_2, f_1 \rangle$$

lead to

$$\frac{\partial E}{\partial v} = 0, \quad \frac{\partial \lambda}{\partial v} = 0, \quad \frac{\partial \left(\frac{\lambda}{\sqrt{G}} \right)}{\partial v} = 0.$$

From the first we see that we can alter the immersion f so that $E = 1$ everywhere. From the third we see that we can likewise arrange that $\lambda = \sqrt{G}$ everywhere. Then our metric has the form

$$du \otimes du + \lambda(u)^2 dv \otimes dv,$$

as desired.

Most of these local results are rather unsatisfying, since they usually require some subsidiary conditions of the same nature as those used in the classical classification of flat surfaces. But there are certain questions where local results are precisely what we should be interested in. We have already seen (pages 209–210) that there are isometric compact surfaces in \mathbb{R}^3 which cannot be connected by a bending. But it seems likely that isometric surfaces can *locally* be connected by a bending. Actually, the argument on page 210 shows that even this is false, since a surface of positive curvature can never be bent into its mirror image. So we should instead conjecture that given any two isometric surfaces, the first can locally be connected by a bending to the second or else to its mirror image.

To investigate this question, we consider once again the Darboux equation. From the considerations on pages 143–146 we see that the immersions $f = (u, v, w): U \rightarrow \mathbb{R}^3$ defined in a neighborhood of $0 \in \mathbb{R}^2$ such that

- (i) $I_f = E dx \otimes dx + F[dx \otimes dy + dy \otimes dx] + G dy \otimes dy$
- (ii) $w(0) = w_1(0) = w_2(0) = 0$
- (iii) $u(0) = v(0) = 0$
- (iv) $u_1(0) = 0, \quad u_2(0) > 0, \quad v_1(0) > 0$

are in one-one correspondence with the solutions w of the Darboux equation which satisfy (ii). Writing the Darboux equation as on page 146 [equation (6)], we see that the following holds:

- (*) Let E, F, G be the components of a metric in a neighborhood of $0 \in \mathbb{R}^2$, and let ρ, σ be two functions in a neighborhood of $0 \in \mathbb{R}$ with

$$\begin{aligned}\rho(0) &= \rho'(0) = \sigma(0) = 0 \\ \rho''(0) &\neq 0.\end{aligned}$$

Assume E, F, G and ρ, σ are analytic, unless the curvature K satisfies $K(0) < 0$. Then there is a unique immersion $f = (u, v, w)$ defined in a neighborhood of $0 \in \mathbb{R}^2$ such that (i)–(iv) hold, and for which

$$w(x, 0) = \rho(x), \quad w_2(x, 0) = \sigma(x).$$

From this observation it is but a short step to

18. LEMMA. Let $\phi: M \rightarrow \bar{M}$ be an isometry between two surfaces $M, \bar{M} \subset \mathbb{R}^3$ and let $X \in M_p$ be a vector such that $\text{II}(X_p, X_p)$ and $\bar{\text{II}}(\phi_* X_p, \phi_* X_p)$ are either both positive or both negative. Assume that M and \bar{M} are analytic surfaces, unless $K(p) < 0$. Then there is a neighborhood U of p and a bending $\alpha: [0, 1] \times U \rightarrow \mathbb{R}^3$ with $\bar{\alpha}(0) = \text{identity}$ and $\bar{\alpha}(1) = \phi$.

PROOF. Choose immersions $f = (u, v, w)$ and $\bar{f} = (\bar{u}, \bar{v}, \bar{w})$ taking a neighborhood of $0 \in \mathbb{R}^2$ into M and \bar{M} , respectively, with $f(0) = p$ and $\bar{f}(0) = \phi(p)$. Without loss of generality we can assume that both f and \bar{f} satisfy the conditions (ii)–(iv) above, and that $X_p = f_*((1, 0))$ and $\phi_* X_p = \bar{f}_*((1, 0))$. Let $I_f = I_{\bar{f}}$ have components E, F, G . For $0 \leq t \leq 1$, let

$$\begin{aligned}\rho_t(x) &= (1 - t)w(x, 0) + t\bar{w}(x, 0) \\ \sigma_t(x) &= (1 - t)w_2(x, 0) + t\bar{w}_2(x, 0).\end{aligned}$$

Then (ii) gives

$$(1) \quad \rho_t(0) = \rho'_t(0) = \sigma_t(0) = 0.$$

If l, m, n and $\bar{l}, \bar{m}, \bar{n}$ are the coefficients of II_f and $\text{II}_{\bar{f}}$, then by assumption $\text{II}(X_p, X_p) = l(0, 0)$ and $\bar{\text{II}}(\phi_* X_p, \phi_* X_p) = \bar{l}(0, 0)$ have the same sign. Now

$$\begin{aligned}l(0, 0) &= \frac{1}{\sqrt{EG - F^2}} \cdot \det \begin{pmatrix} f_{11} \\ f_1 \\ f_2 \end{pmatrix} \quad \text{at } (0, 0) \quad [\text{formula (A) of Chapter 3}] \\ &= \frac{1}{\sqrt{EG - F^2}} \cdot \det \begin{pmatrix} u_{11} & v_{11} & w_{11} \\ u_1 & v_1 & w_1 \\ u_2 & v_2 & w_2 \end{pmatrix} \quad \text{at } (0, 0)\end{aligned}$$

$$= \frac{1}{\sqrt{EG - F^2}}(0, 0) \cdot w_{11}(0, 0) \cdot u_2(0, 0) \cdot v_1(0, 0) \quad \text{by (ii) and (iv),}$$

and similarly for $\bar{l}(0, 0)$. Using (iv), we see that $w_{11}(0)$ has the same sign as $l(0, 0)$, and similarly for $\bar{w}_{11}(0)$; so $w_{11}(0)$ and $\bar{w}_{11}(0)$ have the same sign. It follows that

$$(2) \quad \rho_t''(0) \neq 0.$$

By (*), there are unique immersions $f_t = (u_t, v_t, w_t)$ defined in a neighborhood of $0 \in \mathbb{R}^2$ such that (i)–(iv) hold, and for which

$$w_t(x, 0) = \rho_t(x), \quad (w_t)_2(x, 0) = \sigma_t(x).$$

The uniqueness implies that $f_0 = f$ and $f_1 = \bar{f}$.

The only details which need to be checked are that all f_t can be defined in a common neighborhood of $0 \in \mathbb{R}^2$, and that the f_t vary smoothly with t . This unrewarding task is left to the reader. ♦

19. THEOREM (E. E. LEVI). Let $\phi: M \rightarrow \bar{M}$ be an isometry between two surfaces $M, \bar{M} \subset \mathbb{R}^3$, and suppose that $p \in M$ and $\phi(p) \in \bar{M}$ are not planar points. Assume that M and \bar{M} are analytic surfaces, unless $K(p) < 0$. Then there is a neighborhood U of p and a bending $\alpha: [0, 1] \times U \rightarrow \mathbb{R}^3$ with $\bar{\alpha}(0) = \text{identity}$ and either $\bar{\alpha}(1) = \phi$ or $\bar{\alpha}(1) = R \circ \phi$, where R is a reflection.

PROOF. Since p and $\phi(p)$ are not planar points, there are at most 2 asymptotic directions at these points, and thus certainly a tangent vector $X \in M_p$ such that $\text{II}(X, X)$ and $\bar{\text{II}}(\phi_*X, \phi_*X)$ are both non-zero. If they have the same sign we apply Lemma 18; if they have opposite signs we apply Lemma 18 to M and $R(\bar{M})$. ♦

We know that the reflection R has to be allowed if $K(p) > 0$. It turns out that R is unnecessary if $K(p) < 0$. We begin with a preliminary result.

20. LEMMA. Let E, F, G be the components of a metric in a neighborhood of $0 \in \mathbb{R}^2$, and $\mathbf{v} \in \mathbb{R}^2_0$ a given tangent vector. Assume that E, F, G are analytic, unless $K < 0$. Then there is an immersion $f = (u, v, w)$ in a neighborhood of 0 such that I_f has components E, F, G , and $f_*(\mathbf{v})$ is not an asymptotic vector on the image of f .

PROOF. Without loss of generality, we can assume that $\mathbf{v} = (1, 0)$. Then choose any two functions ρ, σ satisfying

$$\begin{aligned}\rho(0) &= \rho'(0) = \sigma(0) = 0 \\ \rho''(0) &\neq 0,\end{aligned}$$

and consider the immersion f determined by $(*)$, with

$$\begin{aligned}u_2(0) &> 0, & v_1(0) &> 0 \\ w(x, 0) = \rho(x) &\implies w_{11}(0, 0) = \rho''(0).\end{aligned}$$

The calculation in the proof of Lemma 18 shows that

$$l(0, 0) = \frac{1}{\sqrt{EG - F^2}}(0, 0) \cdot w_{11}(0, 0) \cdot u_2(0, 0) \cdot v_1(0, 0) \neq 0.$$

This means that $f_*(\mathbf{v})$ is not an asymptotic vector. \blacklozenge

21. THEOREM (E. E. LEVI). Let $\phi: M \rightarrow \bar{M}$ be an isometry between two surfaces $M, \bar{M} \subset \mathbb{R}^3$, and suppose that $K(p) < 0$. Then there is a neighborhood U of p and a bending $\alpha: [0, 1] \times U \rightarrow \mathbb{R}^3$ with $\bar{\alpha}(0) = \text{identity}$ and $\bar{\alpha}(1) = \phi$.

PROOF. We just have to show that a neighborhood of p in M can be bent into its mirror image $R(M)$. Let $X \in M_p$ be an asymptotic vector. Then there are vectors Y arbitrarily close to X in M_p with $\text{II}(Y, Y) > 0$, as well as vectors arbitrarily close to X with $\text{II}(Y, Y) < 0$. Lemma 20 says that there is (locally) an isometry $\psi: M \rightarrow \tilde{M} \subset \mathbb{R}^3$ such that $\psi_*(X)$ is *not* an asymptotic vector on \tilde{M} . We can assume, by composing \tilde{M} with a reflection if necessary, that $\tilde{\text{II}}(\psi_*X, \psi_*X) > 0$. Then the same inequality holds for all tangent vectors of $\tilde{M}_{\psi(p)}$ in some sector containing ψ_*X . So we can choose $Y \in M_p$ with

$$\text{II}(Y, Y) > 0, \quad \tilde{\text{II}}(\psi_*Y, \psi_*Y) > 0,$$

and it follows from Theorem 19 that there is a bending of a neighborhood of p in M onto a neighborhood of $\psi(p)$ in \tilde{M} . But we can also choose $Y \in M_p$ with

$$\text{II}(Y, Y) < 0, \quad \tilde{\text{II}}(\psi_*Y, \psi_*Y) > 0,$$

and then it follows that there is a bending of a neighborhood of $R(p)$ in $R(M)$ onto a neighborhood of $\psi(p)$ in \tilde{M} . Consequently, there is a bending of a neighborhood of p in M onto a neighborhood of $R(p)$ in $R(M)$. \blacklozenge

This little proof, clever as it is, certainly doesn't give any idea of what is going on geometrically. E. E. Levi supplied a geometric description of the bending in the special case of a surface M of constant negative curvature whose asymptotic directions are perpendicular at $p \in M$. Rotation through an angle of $\pi/2$

around the normal at p takes M into its reflection R through the tangent plane at p . But the isometry $M \rightarrow R(M)$ thus obtained is not the same as $R|M$. To modify this, we consider the series of isometries obtained as follows. At time t , we first perform a rotation A_t through an angle t around the normal, and then compose $A_t|M$ with a map $B_t: A_t(M) \rightarrow A_t(M)$ of the surface of constant curvature $A_t(M)$ onto itself which rotates the tangent space M_p back by an angle of $-t$. For $t = \pi/2$ we obtain the map $R|M$.

These results of E. E. Levi [1] were proved nearly 30 years after A. Voss had first explicitly pointed out that a distinction ought to be made between warpings and bendings. Levi's results were regarded as demonstrations that these distinctions really did not exist (at least locally). Of course, Theorem 19 does have the added hypothesis that p and $\phi(p)$ are not planar points; in E. E. Levi's original theorem, there was the stronger requirement that $K(p) \neq 0$. Such requirements were regarded, if they were regarded at all, as merely technical details. Remarkably enough, H. Schilt [1] discovered that Theorem 19 is actually false if the point p is a flat point, even if all points in a neighborhood of p have $K < 0$. We will outline the arguments here, but for some of the details the reader is referred to Schilt's paper, which is very clearly written and easy to follow.

Consider a surface M which is the graph of a function $h: \mathbb{R}^2 \rightarrow \mathbb{R}$ with $0 = h(0) = h_1(0) = h_2(0)$. If the curvature $K(0) < 0$, then M looks like a "saddle", as we saw in Chapter 2. But if $K(0) = 0$, and $K < 0$ in a deleted neighborhood of 0, then it can be shown that M looks like a "generalized

monkey saddle”: inside a sufficiently small circle C around 0, the zero set of h

consists of an even number 2λ of curves starting at 0 and ending at C , with no points in common except 0; the sign of h on the sectors between these curves

is constant and changes as we go from one sector to another. The number $s = \lambda - 1$ is called the **order** of the saddle point at 0. An ordinary saddle point, where $K(0) < 0$, has order 1, while the monkey saddle has order 2. The graph of $h(x, y) = \operatorname{Re}(x + iy)^{s+1}$ has order s .

The order of a saddle point can be described in another way, by considering a closed curve in M going once around p in the positively oriented sense. It turns out that the image of this curve under the normal map goes s times around the normal at p , but in the negatively oriented sense. The following picture illustrates this for the monkey saddle.

Finally, the order of a saddle point may be described in yet a third way. In the region where $K < 0$, the principal curvatures k_1, k_2 are of different signs, say $k_1 > 0 > k_2$. So we can pick out the 1-dimensional distribution of all multiples of the principal directions corresponding to the principal curvature k_1 , say. Notice that if $X_p \in M_p$ is a principal direction with principal curvature k_1 , and \bar{X}_p is a perpendicular vector with (X_p, \bar{X}_p) positively oriented, then there is just one unit asymptotic vector Y_p in the quadrant of M_p bounded by X_p and \bar{X}_p . Moreover, if we start with $-X_p$ instead of X_p , then we just end up

with $-Y_p$. Thus we can also pick out a 1-dimensional distribution consisting of all multiples of an asymptotic vector at each point.

Another way of stating these facts is the following: the principal curves and the asymptotic curves can each be separated into two distinct families in the region where $K < 0$.^{*} The following picture shows the projections on the (x, y) -plane of the two families of asymptotic lines (one indicated by solid lines, the other by dotted lines) for the ordinary monkey saddle.

^{*}Schilt [1] tries to do this for the asymptotic curves by looking at the signs of their torsions, which have to be different by the Beltrami-Enneper theorem. But this doesn't work at points where the torsions don't exist.

Now one can define the index of any one of these distributions (Addendum 2 to Chapter 4); this index i is a half-integer, and is clearly the same for both families. It is related to the order s of the saddle by

$$(*) \quad s = 1 - 2i.$$

For example, the monkey saddle, with $s = 2$, has $i = -1/2$ (compare the above picture with the one on pg. III.219). On the other hand, if 0 is a parabolic point, then the asymptotic curves have no singularity at 0, so $i = 0$ and $s = 1$, just as in the case of an ordinary saddle point.

Proving $(*)$ is not completely straightforward, but the relation is very important, for it leads immediately to the result that s is a bending invariant: given a bending $\alpha: [0, 1] \times M \rightarrow \mathbb{R}^3$ of the inclusion map of M into \mathbb{R}^3 , each surface $\bar{\alpha}(t)(M)$ has a saddle at $\alpha(t, 0)$, and for all t the order of this saddle is s . For the proof one merely observes that the principal curves or asymptotic curves vary continuously, and therefore always have the same index.

One might think that this result is hardly worth mentioning, on the grounds that s should actually be a warping invariant: any surface isometric to M also ought to have a saddle of order s . But this is *not* true! For suppose that M is an analytic surface with a saddle of order $s > 1$. By Lemma 20, there is a surface \bar{M} isometric to M such that the point corresponding to p is a parabolic point. Thus the saddle order at this point is $\bar{s} = 1$. Consequently, there is no bending from M to \bar{M} ; indeed, no neighborhood of the saddle point on M can be bent onto its isometric image in \bar{M} !

These examples of isometric surfaces which are not even locally connected by a bending all have $K < 0$ in a neighborhood of the point with $K = 0$. But Hopf and Schilt [1] show that, for certain classes of surfaces, the order of contact of the graph of h with the (x, y) -plane is also a bending invariant, but not a warping invariant. This allows them to give examples of the same phenomenon, but for surfaces with $K = 0$ at one point and $K > 0$ in a neighborhood of the point. They are also able to show that Theorem 21 fails if $K(p) = 0$, even if $K < 0$ for all other points in a neighborhood of p .

It should be mentioned that the present proofs of Theorems 19 and 21 (which slightly strengthen E. E. Levi's original result) are due to Schilt, who also observed that the above analysis of the Darboux equation can be used to prove the following: If $p \in M$ is not a planar point, then [assuming M is analytic, unless $K(p) < 0$] some neighborhood of p has a non-trivial bending. Actually, this result holds without assumptions of analyticity when $K(p) > 0$, although the proof is much harder; in fact, this comes out of the proof that a convex surface with a disc deleted is bendable (see Hellwig [1]). However, the case $K(p) = 0$

is unresolved. There is a startling result of Efimov along these lines (see Efimov {1}, Chapter IX, and Hoesli [1]): There exist infinitely many examples of analytic surfaces containing a point p such that no neighborhood of p has any non-trivial analytic bendings; in fact, any smooth bending of this neighborhood into analytic surfaces is trivial. A specific example is $\{(x, y, z) : z = (x^2 + y^2)^5\}$ with $p = 0 \in \mathbb{R}^3$. Whether there are examples where no neighborhood has any non-trivial bendings into C^∞ surfaces is unknown, and certainly a highly intriguing question. As far as I can tell, it is not even known whether every C^∞ surface is locally warpable.

With these considerations we finally end our investigation of rigidity for surfaces in \mathbb{R}^3 . So far we have said absolutely nothing about surfaces in S^3 or H^3 . Recollection of Chapter 7F might make even the stoutest hearts quail at this prospect, but fortunately there is an incredibly neat trick, due to Pogorelov {3}, which reduces almost all such questions to the case of surfaces in \mathbb{R}^3 . Since Pogorelov's book is written more in the style of the Russian school, and includes many results specifically tailored for such a study, we will give a treatment of the main points totally from the C^∞ point of view.

In Chapter 7A we considered the central projection $\phi: S^{n+} \rightarrow \mathbb{R}^n$, from the open northern hemisphere S^{n+} of S^n onto \mathbb{R}^n . It is easily computed that

$$\phi(x) = \left(\frac{x_1}{x_{n+1}}, \dots, \frac{x_n}{x_{n+1}} \right) \quad \text{for } x \in S^{n+}.$$

Let $*$ = $(0, \dots, 0, 1)$ be the north pole of S^n . Then ϕ can also be described by

$$\phi(x) = \frac{x - \langle x, * \rangle \cdot *}{\langle x, * \rangle} \in \mathbb{R}^n \times \{0\} \subset \mathbb{R}^{n+1}.$$

Now let $f_1, f_2: M \rightarrow S^n$ be two maps of a Riemannian manifold M into S^n . Define $\bar{f}_1: M \rightarrow \mathbb{R}^n$ (actually, into $\mathbb{R}^n \times \{0\}$) by

$$(*) \quad \bar{f}_1(p) = \frac{f_1(p) - \langle f_1(p), * \rangle \cdot *}{\langle f_1(p) + f_2(p), * \rangle},$$

and define \bar{f}_2 similarly (this formula makes sense so long as $f_1 + f_2$ is never perpendicular to $*$, which happens, in particular, if f_1 and f_2 both go into S^{n+}).

22. PROPOSITION. The two maps $f_1, f_2: M \rightarrow S^n$ induce the same (possibly degenerate) metric on M if and only if the two maps $\bar{f}_1, \bar{f}_2: M \rightarrow \mathbb{R}^n$ induce the same metric on M .

PROOF. For the \mathbb{R}^n -valued form df_1 we compute from equation (*) that

$$(1) \quad \langle f_1 + f_2, * \rangle^2 df_1 = \langle f_1 + f_2, * \rangle [df_1 - \langle df_1, * \rangle \cdot *] \\ - \langle df_1 + df_2, * \rangle \cdot [f_1 - \langle f_1, * \rangle \cdot *].$$

[This equation means that

$$(2) \quad \langle f_1(p) + f_2(p), * \rangle^2 df_1(X) \\ = \langle f_1(p) + f_2(p), * \rangle [df_1(X) - \langle df_1(X), * \rangle \cdot *] \\ - \langle df_1(X) + df_2(X), * \rangle \cdot [f_1(p) - \langle f_1(p), * \rangle \cdot *]$$

for all $X \in M_p$.]

Since $\langle f_1, f_1 \rangle = 1 \implies \langle df_1, f_1 \rangle = 0$, we have

$$\begin{aligned} \langle f_1 + f_2, * \rangle^4 |df_1|^2 &= \langle f_1 + f_2, * \rangle^2 [|df_1|^2 - \langle df_1, * \rangle^2] \\ &\quad + 2\langle f_1 + f_2, * \rangle \langle df_1 + df_2, * \rangle \langle f_1, * \rangle \langle df_1, * \rangle \\ &\quad + \langle df_1 + df_2, * \rangle^2 [1 - \langle f_1, * \rangle^2] \\ &= \langle f_1 + f_2, * \rangle^2 |df_1|^2 + \langle df_1 + df_2, * \rangle^2 \\ &\quad - [\langle f_1 + f_2, * \rangle \langle df_1, * \rangle - \langle df_1 + df_2, * \rangle \langle f_1, * \rangle]^2 \\ &= \langle f_1 + f_2, * \rangle^2 |df_1|^2 + \langle df_1 + df_2, * \rangle^2 \\ &\quad - [\langle f_2, * \rangle \langle df_1, * \rangle - \langle df_2, * \rangle \langle f_1, * \rangle]^2, \end{aligned}$$

which is symmetric in f_1 and f_2 if and only if $|df_1|^2 = |df_2|^2$. ♦

Remark: Even if f_1 and f_2 are immersions, the maps \bar{f}_1 and \bar{f}_2 need not be. However, if $*$ is not a linear combination of $f_1(p)$ and any vector $df_1(X)$ for $X \in M_p$, then the vectors $df_1(x) - \langle df_1(X), * \rangle *$ and $f_1(p) - \langle f_1(p), * \rangle *$ in (2) are linearly independent, so $d\bar{f}_1(X) \neq 0$ for all $X \in M_p$, and \bar{f}_1 is an immersion at p .

Suppose we have two maps $f_1, f_2: M \rightarrow \mathbb{R}^n \subset \mathbb{R}^{n+1}$. We define $\hat{f}_1: M \rightarrow S^n$ by

$$\hat{f}_1(p) = \frac{2f_1(p) + (1 - |f_1(p)|^2 + |f_2(p)|^2) \cdot *}{|2f_1(p) + (1 - |f_1(p)|^2 + |f_2(p)|^2) \cdot *|},$$

and we define $\hat{f}_2: M \rightarrow S^n$ similarly. It is easy to compute that if we begin with two maps $f_1, f_2: M \rightarrow S^n$, form $\bar{f}_1, \bar{f}_2: M \rightarrow \mathbb{R}^n$ as before, and then apply the present construction to \bar{f}_1, \bar{f}_2 , obtaining $\hat{\bar{f}}_1, \hat{\bar{f}}_2: M \rightarrow S^n$, then

$$\hat{\bar{f}}_1 = f_1, \quad \hat{\bar{f}}_2 = f_2.$$

Similarly, if we start with $f_1, f_2: M \rightarrow \mathbb{R}^n$, then

$$\bar{\bar{f}}_1 = f_1, \quad \bar{\bar{f}}_2 = f_2.$$

Hence

23. COROLLARY. The two maps $f_1, f_2: M \rightarrow \mathbb{R}^n$ induce the same metric on M if and only if the two maps $\hat{f}_1, \hat{f}_2: M \rightarrow S^n$ induce the same metric on M .

On the other hand, our new constructions also preserve the notion of congruence.

24. PROPOSITION. Let A be an orthogonal map of \mathbb{R}^{n+1} , so that $A: S^n \rightarrow S^n$ is an isometry, and let $f_1, f_2: M \rightarrow S^n$ be maps with $f_2 = A \circ f_1$. Suppose that we can define $\bar{f}_1, \bar{f}_2: M \rightarrow \mathbb{R}^n$. Then there is a Euclidean motion $\bar{A}: \mathbb{R}^n \rightarrow \mathbb{R}^n$ such that $\bar{f}_2 = \bar{A} \circ \bar{f}_1$.

PROOF. We just have to show that

$$|\bar{f}_1(p) - \bar{f}_1(q)|^2 = |\bar{f}_2(p) - \bar{f}_2(q)|^2$$

for all $p, q \in M$. For any x with $x + Ax$ not perpendicular to $*$, let $x^\# \in \mathbb{R}^{n+1}$ be a multiple of x such that

$$(I) \quad \langle x^\# + Ax^\#, * \rangle = 1.$$

Then

$$\bar{f}_1(p) = \frac{f_1(p) - \langle f_1(p), * \rangle *}{\langle f_1(p) + A(f_1(p)), * \rangle} = f_1(p)^\# - \langle f_1(p)^\#, * \rangle \cdot *,$$

and similarly for $\bar{f}_1(q), \bar{f}_2(p), \bar{f}_2(q)$. Set $z = f_1(p)^\# - f_1(q)^\#$. Then

$$\begin{aligned} |\bar{f}_1(p) - \bar{f}_1(q)|^2 &= |z - \langle z, * \rangle \cdot *|^2 = |z|^2 - \langle z, * \rangle^2 \\ |\bar{f}_2(p) - \bar{f}_2(q)|^2 &= |Az - \langle Az, * \rangle \cdot *|^2 = |Az|^2 - \langle Az, * \rangle^2. \end{aligned}$$

But $|Az| = |z|$, while

$$\begin{aligned} \langle z + Az, * \rangle &= \langle f_1(p)^\# + Af_1(p)^\# - [f_1(q)^\# + Af_1(q)^\#], * \rangle = 0, \quad \text{by (I)} \\ \implies \langle z, * \rangle^2 &= \langle Az, * \rangle^2. \quad \spadesuit \end{aligned}$$

25. PROPOSITION. Let $B: \mathbb{R}^n \rightarrow \mathbb{R}^n$ be an isometry, and let $f_1, f_2: M \rightarrow \mathbb{R}^n$ be maps with $f_2 = B \circ f_1$. Then there is an isometry $A: S^n \rightarrow S^n$ such that $\hat{f}_2 = A \circ \hat{f}_1$.

PROOF. Define $\rho_1, \rho_2: \mathbb{R}^n \rightarrow S^n$ by

$$\rho_1(y) = \frac{2y + (1 - |y|^2 + |By|^2) \cdot *}{|\text{numerator}|}$$

$$\rho_2(y) = \frac{2y + (1 - |y|^2 + |B^{-1}y|^2) \cdot *}{|\text{numerator}|},$$

so that

$$\hat{f}_1 = \rho_1 \circ f_1, \quad \hat{f}_2 = \rho_2 \circ f_2.$$

It is clear that ρ_1 and ρ_2 are continuous. We claim that ρ_1 and ρ_2 are one-one. Suppose instead that $y \neq z \in \mathbb{R}^n$, but $\rho_1(y) = \rho_1(z)$. Clearly y and z must be linearly dependent, so there is a unit vector $v \in \mathbb{R}^n$ with $y = \lambda v$ and $z = \mu v$. Then $\rho_1(y) = \rho_1(z)$ implies that

$$\frac{2\lambda}{|\text{numerator for } \rho_1(y)|} = \frac{2\mu}{|\text{numerator for } \rho_1(z)|}$$

$$\frac{1 - \lambda^2 + |By|^2}{|\text{numerator for } \rho_1(y)|} = \frac{1 - \mu^2 + |Bz|^2}{|\text{numerator for } \rho_1(z)|},$$

and hence

$$(1) \quad \frac{1 - \lambda^2 + |By|^2}{\lambda} = \frac{1 - \mu^2 + |Bz|^2}{\mu}.$$

Let $B = T_w \circ C$, where C is a rotation, and T_w is translation by a vector w . Then

$$|By|^2 = |C(\lambda v) + w|^2 = \lambda^2 + 2\langle C(\lambda v), w \rangle + |w|^2$$

$$|Bz|^2 = \mu^2 + 2\langle C(\mu v), w \rangle + |w|^2.$$

So (1) becomes

$$\frac{1 + |w|^2}{\lambda} + 2\langle C(v), w \rangle = \frac{1 + |w|^2}{\mu} + 2\langle C(v), w \rangle.$$

Hence $\lambda = \mu \implies y = z$. Similarly, ρ_2 is one-one.

Since ρ_1 and ρ_2 are continuous one-one maps between manifolds of the same dimension, their images are open, by Invariance of Domain (Theorem I.1-1). So we can consider the map $\rho_2 \circ B \circ \rho_1^{-1}$, defined on some open set in S^n . We claim that this map preserves distances on S^n , and is thus the restriction of some isometry A . Since

$$\hat{f}_2 = \rho_2 \circ f_2 = \rho_2 \circ B \circ f_1 = \rho_2 \circ B \circ \rho_1^{-1} \circ \rho_1 \circ f_1 = \rho_2 \circ B \circ \rho_1^{-1} \circ \hat{f}_1,$$

this will prove the Theorem.

It suffices to show that

$$|\rho_1(y) - \rho_1(z)|^2 = |\rho_2(By) - \rho_2(Bz)|^2,$$

since the distance between two points in S^n is determined by their Euclidean distance. Clearly, we just have to show that for all y and z we have

$$\langle \rho_1(y), \rho_1(z) \rangle = \langle \rho_2(By), \rho_2(Bz) \rangle.$$

If

$$\begin{aligned} a(y) &= 2y + (1 - |y|^2 + |By|^2) \cdot * \\ b(y) &= 2By + (1 - |By|^2 + |y|^2) \cdot *, \end{aligned}$$

then

$$\rho_1(y) = \frac{a(y)}{|a(y)|}, \quad \rho_2(By) = \frac{b(y)}{|b(y)|}.$$

So it suffices to show that for all $y, z \in \mathbb{R}^n$ we have

$$(2) \quad \langle a(y), a(z) \rangle = \langle b(y), b(z) \rangle.$$

Now

$$(3) \quad \begin{cases} \langle a(y), a(z) \rangle = 4\langle y, z \rangle + (1 - |y|^2 + |By|^2)(1 - |z|^2 + |Bz|^2) \\ \langle b(y), b(z) \rangle = 4\langle By, Bz \rangle + (1 - |By|^2 + |y|^2)(1 - |Bz|^2 + |z|^2). \end{cases}$$

Writing $B = T_w \circ C$ as before, we have

$$\begin{aligned} |By|^2 &= |y|^2 + 2\langle Cy, w \rangle + |w|^2 \\ |Bz|^2 &= |z|^2 + 2\langle Cz, w \rangle + |w|^2, \end{aligned}$$

and

$$\langle By, Bz \rangle = \langle y, z \rangle + \langle Cy + Cz, w \rangle + |w|^2.$$

Substituting into (3), we obtain (2). ♦

The hardest problem is to show that our construction preserves convexity. This holds only in certain circumstances, which requires a preliminary remark. We say that a hypersurface $M \subset S^{n+}$ is **star-shaped with respect to $*$** if each geodesic ray starting from $*$, and contained in S^{n+} , intersects M exactly once. Clearly M has a natural orientation, just as in the case of hypersurfaces $M \subset \mathbb{R}^n$ that are star-shaped with respect to 0. Our results will hold only for imbeddings $f_1, f_2: M \rightarrow S^{n+}$ or \mathbb{R}^n whose images are star-shaped with respect to $*$ or 0; moreover, for some orientation on M , the induced orientations on $f_1(M)$ and $f_2(M)$ must be the natural ones.

Before giving the precise results, we consider one more preliminary. Let γ be an arclength parameterized curve in S^n . Then the Frenet equations for S^n give

$$\begin{aligned}\kappa(s)\mathbf{n}(s) &= \frac{D\gamma'(s)}{ds} = \mathbf{T}\gamma''(s) \\ &= \gamma''(s) - \langle \gamma''(s), \gamma(s) \rangle \cdot \gamma(s).\end{aligned}$$

But

$$\langle \gamma, \gamma \rangle = 1 \implies \langle \gamma', \gamma \rangle = 0 \implies \langle \gamma'', \gamma \rangle = -\langle \gamma', \gamma' \rangle = -1.$$

So we have

$$\gamma''(s) = \kappa(s)\mathbf{n}(s) - \gamma(s).$$

Hence

$$\begin{aligned}(\ast) \quad \gamma(s+h) &= \gamma(s) + h\gamma'(s) + \frac{h^2}{2}\gamma''(s) + o(h^2) \\ &= \left(1 - \frac{h^2}{2}\right)\gamma(s) + h\mathbf{t}(s) + \frac{h^2}{2}\kappa(s)\mathbf{n}(s) + o(h^2).\end{aligned}$$

26. PROPOSITION. Let M be an oriented $(n-1)$ -manifold, and let $f_1, f_2: M \rightarrow S^{n+}$ be two imbeddings such that $f_1(M)$ and $f_2(M)$ are convex and star-shaped with respect to $*$, and such that f_1 and f_2 induce the same metric on M , and the natural orientations on $f_1(M)$ and $f_2(M)$. Suppose, moreover, that the second fundamental forms of $f_1(M)$ and $f_2(M)$ are positive semi-definite. Then the same is true for the second fundamental forms of $\bar{f}_1(M)$ and $\bar{f}_2(M)$ in \mathbb{R}^n . (Note that under the given hypotheses, \bar{f}_1 and \bar{f}_2 will be immersions, by the Remark after Proposition 22.)

PROOF. Let c be an arclength parameterized curve in M (with the metric induced by f_1 or f_2). Apply (\ast) to the arclength parameterized curve $\gamma = f_1 \circ c$

in S^n , letting \mathbf{t}_1 and \mathbf{n}_1 be its tangent and normal, and κ_1 its curvature. We obtain

$$\begin{aligned} f_1(c(s+h)) &= \left(1 - \frac{h^2}{2}\right) f_1(c(s)) + h\mathbf{t}_1(s) + \frac{h^2}{2}\kappa_1(s)\mathbf{n}_1(s) + o(h^2) \\ &= \left(1 - \frac{h^2}{2}\right) x_1 + h\mathbf{t}_1 + \frac{h^2}{2}\kappa_1\mathbf{n}_1 + o(h^2) \quad \text{for short,} \end{aligned}$$

and similarly

$$\begin{aligned} f_2(c(s+h)) &= \left(1 - \frac{h^2}{2}\right) f_2(c(s)) + h\mathbf{t}_2(s) + \frac{h^2}{2}\kappa_2(s)\mathbf{n}_2(s) + o(h^2) \\ &= \left(1 - \frac{h^2}{2}\right) x_2 + h\mathbf{t}_2 + \frac{h^2}{2}\kappa_2\mathbf{n}_2 + o(h^2) \quad \text{for short.} \end{aligned}$$

So

$$\begin{aligned} (1) \quad \bar{f}_1(c(s+h)) &= \frac{\left(1 - \frac{h^2}{2}\right) x_1 + h\mathbf{t}_1 + \frac{h^2}{2}\kappa_1\mathbf{n}_1 + o(h^2) - \left\langle \left(1 - \frac{h^2}{2}\right) x_1 + h\mathbf{t}_1 + \frac{h^2}{2}\kappa_1\mathbf{n}_1 + o(h^2), * \right\rangle *}{\left\langle \left(1 - \frac{h^2}{2}\right) (x_1 + x_2) + h(\mathbf{t}_1 + \mathbf{t}_2) + \frac{h^2}{2}(\kappa_1\mathbf{n}_1 + \kappa_2\mathbf{n}_2) + o(h^2), * \right\rangle}. \end{aligned}$$

Writing this as

$$\frac{v - \frac{h^2}{2}v + hV}{\alpha - \frac{h^2}{2}\alpha + hA} \quad \begin{cases} v = x_1 - \langle x_1, * \rangle * \\ \alpha = \langle x_1 + x_2, * \rangle, \end{cases}$$

and noting that

$$\frac{v - \frac{h^2}{2}v + hV}{\alpha - \frac{h^2}{2}\alpha + hA} - \frac{v + hV}{\alpha + hA} = \frac{\frac{h^3}{2}(\alpha V - Av)}{\left(\alpha + \frac{h^2}{2}\alpha + hA\right)(\alpha + hA)},$$

we see that (1) can be written

$$(2) \quad \bar{f}_1(c(s+h)) = \frac{x_1 + h\mathbf{t}_1 + \frac{h^2}{2}\kappa_1\mathbf{n}_1 - \left\langle x_1 + h\mathbf{t}_1 + \frac{h^2}{2}\kappa_1\mathbf{n}_1, * \right\rangle *}{\left\langle x_1 + x_2 + h(\mathbf{t}_1 + \mathbf{t}_2) + \frac{h^2}{2}(\kappa_1\mathbf{n}_1 + \kappa_2\mathbf{n}_2), * \right\rangle} + O(h^3),$$

where $O(h^3)$ denotes a function such that $O(h^3)/h^3$ is bounded as $h \rightarrow 0$.

Expanding equation (2) out up to terms of order h^2 , we find that

$$\begin{aligned}
 (3) \quad & \bar{f}_1(c(s+h)) - \bar{f}_1(c(s)) \\
 &= \frac{h}{\langle x_1 + x_2, * \rangle} \left\{ -\langle \mathbf{t}_1 + \mathbf{t}_2, * \rangle \bar{f}_1(c(s)) + \mathbf{t}_1 - \langle \mathbf{t}_1, * \rangle * \right\} \\
 &+ \frac{h^2 \langle \mathbf{t}_1 + \mathbf{t}_2, * \rangle}{\langle x_1 + x_2, * \rangle^2} \left\{ \langle \mathbf{t}_1 + \mathbf{t}_2, * \rangle \bar{f}_1(c(s)) - \mathbf{t}_1 + \langle \mathbf{t}_1, * \rangle * \right\} \\
 &+ \frac{h^2}{2\langle x_1 + x_2, * \rangle} \left\{ -\langle \kappa_1 \mathbf{n}_1 + \kappa_2 \mathbf{n}_2, * \rangle \bar{f}_1(c(s)) + \kappa_1 \mathbf{n}_1 - \langle \kappa_1 \mathbf{n}_1, * \rangle * \right\} \\
 &+ O(h^3).
 \end{aligned}$$

Let \bar{N}_1 be the unit normal of $\bar{f}_1(M)$ at $\bar{f}_1(c(s))$. Clearly

$$\lim_{h \rightarrow 0} \left\langle \frac{\bar{f}_1(c(s+h)) - \bar{f}_1(c(s))}{h}, \bar{N}_1 \right\rangle = 0.$$

So equation (3) implies that

$$(4) \quad \left\langle -\langle \mathbf{t}_1 + \mathbf{t}_2, * \rangle \bar{f}_1(c(s)) + \mathbf{t}_1 - \langle \mathbf{t}_1, * \rangle *, \bar{N}_1 \right\rangle = 0.$$

Using (4), and the fact that $\langle \bar{N}_1, * \rangle = 0$ (since $\bar{f}_1(M)$ lies in $\mathbb{R}^n \times \{0\}$), equation (3) now gives

$$\begin{aligned}
 (5) \quad & \langle \bar{f}_1(c(s+h)) - \bar{f}_1(c(s)), \bar{N}_1 \rangle \\
 &= \frac{\kappa_1 h^2}{2\langle x_1 + x_2, * \rangle} \left\langle -\langle \mathbf{n}_1, * \rangle \bar{f}_1(c(s)) + \mathbf{n}_1, \bar{N}_1 \right\rangle \\
 &\quad - \frac{\kappa_2 h^2}{2\langle x_1 + x_2, * \rangle} \langle \mathbf{n}_2, * \rangle \langle \bar{f}_1(c(s)), \bar{N}_1 \rangle + O(h^3).
 \end{aligned}$$

Since Taylor's Theorem shows that the second derivative α'' of a function α is given by

$$\alpha''(x) = \lim_{h \rightarrow 0} \frac{\alpha(x+h) + \alpha(x-h) - 2\alpha(x)}{h^2},$$

equation (5) implies that

$$\begin{aligned}
 \langle (\bar{f}_1 \circ c)''(s), \bar{N}_1 \rangle &= \frac{\kappa_1}{\langle x_1 + x_2, * \rangle} \left\langle -\langle \mathbf{n}_1, * \rangle \bar{f}_1(c(s)) + \mathbf{n}_1, \bar{N}_1 \right\rangle \\
 &\quad - \frac{\kappa_2}{\langle x_1 + x_2, * \rangle} \langle \mathbf{n}_2, * \rangle \langle \bar{f}_1(c(s)), \bar{N}_1 \rangle.
 \end{aligned}$$

The term on the left is the second fundamental form of $\bar{f}_1(M)$ applied to $((\bar{f}_1 \circ c)'(s), (\bar{f}_1 \circ c)'(s))$. So it suffices to show that it is always ≥ 0 . Since

$$\frac{\kappa_1}{\langle x_1 + x_2, * \rangle} \geq 0 \quad \text{and} \quad \frac{\kappa_2}{\langle x_1 + x_2, * \rangle} \geq 0,$$

it suffices to show that

$$(6) \quad \left\langle -\langle \mathbf{n}_1, * \rangle \bar{f}_1(c(s)) + \mathbf{n}_1, \bar{N}_1 \right\rangle > 0 \quad \text{and} \quad -\langle \mathbf{n}_2, * \rangle \langle \bar{f}_1(c(s)), \bar{N}_1 \rangle > 0.$$

We can also assume that N_1 is the normal to the tangent plane of $f_1(M)$ at $f_1(c(s))$, since we can choose c so that $f_1 \circ c$ is a normal section of $f_1(M)$. Equation (6) is then proved in the following Lemma, whose statement introduces some more convenient notation.

27. LEMMA. Let P and Q be the tangent planes of $f_1(M)$ and $f_2(M)$ at the points $a_0 = f_1(p)$ and $b_0 = f_2(p)$, and let $c_0 = \bar{f}_1(p)$. Let a_n and b_n be the unit normals to P and Q at a_0 and b_0 , and let c_n be the unit normal to the tangent plane of $\bar{f}_1(M)$ at c_0 . Then

$$\left\langle -\langle a_n, * \rangle c_0 + a_n, c_n \right\rangle > 0 \quad \text{and} \quad -\langle b_n, * \rangle \cdot \langle c_0, c_n \rangle > 0.$$

PROOF. Choose positively oriented unit orthonormal vectors a_1, \dots, a_{n-1} at the point a_0 in P , let b_1, \dots, b_{n-1} be the corresponding vectors at b_0 in Q , and let c_1, \dots, c_{n-1} be the corresponding vectors at c_0 in the tangent plane of $\bar{f}_1(M)$ at c_0 . Then for some $C > 0$ we have

$$(7) \quad a_n = a_0 \times \cdots \times a_{n-1}, \quad b_n = b_0 \times \cdots \times b_{n-1}, \quad c_n = C \cdot * \times c_1 \times \cdots \times c_{n-1}.$$

Apply the formula for $d\bar{f}_1$, in the proof of Proposition 22, to the tangent vector X_i in M_p such that $df(X_i) = a_i$. This gives, in the present notation,

$$\langle a_0 + b_0, * \rangle^2 c_i = \langle a_0 + b_0, * \rangle [a_i - \langle a_1, * \rangle *] - \langle a_i + b_i, * \rangle [a_0 - \langle a_0, * \rangle *],$$

and thus

$$(8) \quad c_i = \frac{1}{\lambda_0^2} (\lambda_0 a_i - \lambda_i a_0) + (\cdots) * \quad i = 1, \dots, n-1,$$

where

$$(9) \quad \lambda_i = \langle a_i + b_i, * \rangle \quad i = 0, \dots, n-1.$$

Note also that c_0 is given by

$$(10) \quad c_0 = \frac{a_0}{\lambda_0} + (\cdots)*.$$

From (7) and (8) we obtain

$$\begin{aligned} (11) \quad c_n &= C \cdot * \times c_1 \times \cdots \times c_{n-1} \\ &= \frac{C}{\lambda_0^{2(n-1)}} \cdot * \times (\lambda_0 a_1 - \lambda_1 a_0) \times \cdots \times (\lambda_0 a_{n-1} - \lambda_{n-1} a_0) \\ &= \frac{C}{\lambda_0^n} \{ \lambda_0 (* \times a_1 \times \cdots \times a_{n-1}) - \lambda_1 (* \times a_0 \times a_2 \times \cdots \times a_{n-1}) \\ &\quad - \cdots - \lambda_{n-1} (* \times a_1 \times \cdots \times a_{n-2} \times a_0) \}. \end{aligned}$$

Consider first the quantity

$$-\langle b_n, * \rangle \cdot \langle c_0, c_n \rangle.$$

First of all, we have

$$\begin{aligned} (12) \quad \langle *, b_n \rangle &= \langle *, b_0 \times \cdots \times b_{n-1} \rangle \quad \text{by (7)} \\ &= \det \begin{pmatrix} b_0 \\ \vdots \\ b_{n-1} \\ * \end{pmatrix}. \end{aligned}$$

Also,

$$\begin{aligned} (13) \quad \langle c_0, c_n \rangle &= \left\langle \frac{a_0}{\lambda_0} + (\cdots)*, c_n \right\rangle \quad \text{by (10)} \\ &= \frac{C}{\lambda_0^n} \langle a_0, * \times a_1 \times \cdots \times a_{n-1} \rangle \quad \text{by (11)} \\ &= -\frac{C}{\lambda_0^n} \det \begin{pmatrix} a_0 \\ \vdots \\ a_{n-1} \\ * \end{pmatrix}. \end{aligned}$$

Since f_1 and f_2 induce the natural orientations on $f_1(M)$ and $f_2(M)$, the determinants in (12) and (13) are both positive. Hence we do indeed have

$$-\langle b_n, * \rangle \cdot \langle c_0, c_n \rangle > 0.$$

Now consider

$$\langle -\langle a_n, * \rangle c_0 + a_n, c_n \rangle.$$

First of all, we have

$$(14) \quad -\langle a_n, * \rangle \cdot \langle c_0, c_n \rangle = \frac{C}{\lambda_0^n} \left[\det \begin{pmatrix} a_0 \\ \vdots \\ a_{n-1} \\ * \end{pmatrix} \right]^2 \quad \text{by (7) and (13).}$$

Also,

$$\begin{aligned} \langle c_n, a_n \rangle &= \frac{C}{\lambda_0^n} \{ \lambda_0 \langle * \times a_1 \times \cdots \times a_{n-1}, a_0 \times \cdots \times a_{n-1} \rangle \\ &\quad - \lambda_1 \langle * \times a_0 \times \cdots \times a_{n-1}, a_0 \times \cdots \times a_{n-1} \rangle - \cdots \\ &\quad - \lambda_{n-1} \langle * \times a_1 \times \cdots \times a_0, a_0 \times \cdots \times a_{n-1} \rangle \} \quad \text{by (11).} \end{aligned}$$

Using the formula (Problem 5)

$$\langle v_1 \times \cdots \times v_n, w_1 \times \cdots \times w_n \rangle = \det(\langle v_i, w_j \rangle),$$

we obtain

$$\langle c_n, a_n \rangle = \frac{C}{\lambda_0^n} \{ \lambda_0 \langle *, a_0 \rangle + \lambda_1 \langle *, a_1 \rangle + \cdots + \lambda_{n-1} \langle *, a_{n-1} \rangle \}.$$

Substituting in from (8) yields

$$\begin{aligned} \langle c_n, a_n \rangle &= \frac{C}{\lambda_0^n} \cdot \sum_{i=0}^{n-1} \langle a_i, * \rangle^2 + \langle a_i, * \rangle \langle b_i, * \rangle \\ &\geq \frac{C}{2\lambda_0^n} \cdot \sum_{i=0}^{n-1} \langle a_i, * \rangle^2 - \langle b_i, * \rangle^2. \end{aligned}$$

Since

$$\sum_{i=0}^n \langle a_i, * \rangle^2 = 1 = \sum_{i=0}^n \langle b_i, * \rangle^2,$$

we get

$$\begin{aligned} (15) \quad \langle c_n, a_n \rangle &\geq \frac{C}{2\lambda_0^n} (\langle *, b_n \rangle^2 - \langle *, a_n \rangle^2) \\ &= \frac{C}{2\lambda_0^n} \left[\left[\det \begin{pmatrix} b_0 \\ \vdots \\ b_{n-1} \\ * \end{pmatrix} \right]^2 - \left[\det \begin{pmatrix} a_0 \\ \vdots \\ a_{n-1} \\ * \end{pmatrix} \right]^2 \right]. \end{aligned}$$

From (14) and (15) we get

$$\langle -\langle a_n, * \rangle c_0 + a_n, c_n \rangle \geq \frac{C}{2\lambda_0^n} \left[\left[\det \begin{pmatrix} b_0 \\ \vdots \\ b_{n-1} \\ * \end{pmatrix} \right]^2 + \left[\det \begin{pmatrix} a_0 \\ \vdots \\ a_{n-1} \\ * \end{pmatrix} \right]^2 \right] > 0. \quad \blacklozenge$$

There is a result analogous to Proposition 26 when we begin with imbeddings into \mathbb{R}^n and construct the imbeddings into S^n , but we will not need it. It is probably already clear how the results which we have just proved can be used to transfer theorems from Euclidean space to the sphere. For example, keeping to dimension 3, which is the really interesting one, suppose we have two compact convex surfaces $M, \bar{M} \subset S^3$ (each contained in some open hemisphere), and an isometry $\alpha: M \rightarrow \bar{M}$. We claim that α is the restriction of an isometry $A: S^3 \rightarrow S^3$. Without loss of generality, we can assume that M and \bar{M} are contained in S^{n+} and are star-shaped with respect to $*$. Let $f_1: M \rightarrow S^{n+}$ be the inclusion map, and let $f_2: M \rightarrow S^{n+}$ be $\alpha \circ f_1$; then f_1 and f_2 induce the same metric on M . We can also assume that M is oriented so that f_1 and f_2 induce the natural orientation on M and \bar{M} , by composing f_2 with a reflection if necessary. Then $\bar{f}_1, \bar{f}_2: M \rightarrow \mathbb{R}^3$ induce the same metric on M , by Proposition 22, and $\bar{f}_1(M)$ and $\bar{f}_2(M)$ have $K \geq 0$ by Proposition 26. So by Theorem 12, there is an isometry $B: \mathbb{R}^3 \rightarrow \mathbb{R}^3$ with $\bar{f}_2 = B \circ \bar{f}_1$. Then Proposition 25 shows that there is an isometry $A: S^3 \rightarrow S^3$ with

$$f_2 = \hat{f}_2 = A \circ \hat{f}_1 = A \circ f_1,$$

which shows that

$$\alpha \circ f_1 = A \circ f_1 \implies \alpha \text{ is the restriction of } A \text{ to } f_1(M) = M.$$

Pogorelov states that essentially the same formulas can be used to transfer rigidity problems from hyperbolic space to Euclidean space, and he shows how problems of infinitesimal rigidity can also be transferred in this way.

We also want to add a few remarks, of a different sort, about hypersurfaces of S^{n+1} and H^{n+1} . The proof of Theorem 1 carries over almost without change to this situation, so hypersurfaces of S^{n+1} or H^{n+1} are rigid if their type number (the rank of $X_p \mapsto \nabla'_{X_p} \nu$) is ≥ 3 at each point p . The hypersurfaces of S^{n+1} and H^{n+1} with type number 2 at all points were studied by Dolbeault-Lemoine [1]. She divides them into the same three classes that É. Cartan found

for hypersurfaces of \mathbb{R}^{n+1} , but it turns out that all hypersurfaces in one of the classes are rigid in S^{n+1} and H^{n+1} for any $n \geq 3$, while the hypersurfaces of the other two classes are rigid in S^{n+1} and H^{n+1} for any $n \geq 4$. Moreover, the hypersurfaces with type number 1 at all points are also rigid in S^{n+1} and H^{n+1} for any $n \geq 4$. This leads her to conclude that for $n \geq 4$, all hypersurfaces of S^{n+1} and H^{n+1} are rigid. Unfortunately, this does not follow directly from the preceding results, for it is conceivable that two hypersurfaces from different classes can be joined together in two isometric, but non-congruent, ways; whether this is actually possible is a question which still has to be cleared up.

The only subject left for us to consider at this point is the rigidity of submanifolds of higher codimension. There are two main results in this direction, a classical local one, and a modern global one.

The classical result involves the notion of the type number of a submanifold $M^n \subset \mathbb{R}^m$ of arbitrary codimension. First an algebraic definition. Let V be a vector space, and let $T_1, \dots, T_k: V \rightarrow V$ be linearly independent linear transformations. We define the **type number** of $\{T_1, \dots, T_k\}$ to be the largest integer t for which there are t vectors $v_1, \dots, v_t \in V$ such that the kt vectors

$$T_r(v_i) \quad 1 \leq i \leq t, \quad 1 \leq r \leq k$$

are linearly independent. The **type number** of linearly independent matrices S_1, \dots, S_k is defined as that of the corresponding linear transformations. Now for a point $p \in M^n \subset \mathbb{R}^m$ we let $k(p)$ be the rank of the map $\xi \mapsto A_\xi$ from M_p^\perp into the space of all symmetric maps of M_p into itself (recall that $A_\xi: M_p \rightarrow M_p$ is defined by $\langle A_\xi(X), Y \rangle = \langle s(X, Y), \xi \rangle$). Equivalently, $k(p)$ is the dimension of the **first normal space** at p , which may be defined as the orthogonal complement in M_p^\perp of $\{\xi: A_\xi = 0\}$ (compare Addendum 4 of Chapter 7). Set $k = k(p)$ and let ξ_1, \dots, ξ_k be a basis for the first normal space at p . If $T_r: M_p \rightarrow M_p$ is A_{ξ_r} for $r = 1, \dots, k$, then T_1, \dots, T_k are linearly independent, and we can define the **type number** $t(p)$ of M at p to be the type number of $\{T_1, \dots, T_k\}$; it is easily checked that this definition does not depend on the choice of ξ_1, \dots, ξ_k . The following result shows that submanifolds with type number at least 2 cannot twist too much.

28. LEMMA. Let N^m be a manifold of constant curvature, and let M^n be a submanifold with normal connection D , whose first normal space $\text{Nor}^1 M_p$ has the same dimension k at all points, and whose type number is ≥ 2 at all points. Then $D_Z \xi \in \text{Nor}^1 M_p$ for any section ξ of $\text{Nor}^1 M_p$ and $Z \in M_p$.

Consequently, if M is connected, then it lies in some $(n + k)$ -dimensional totally geodesic subspace of N .

PROOF. Locally we can choose orthonormal sections v_{n+1}, \dots, v_m of $\text{Nor } M$ such that v_{n+1}, \dots, v_{n+k} span $\text{Nor}^1 M$. Then $A_{v_r} = 0 \implies \text{II}^r = 0$ for $r > n + k$. So the Codazzi-Mainardi equations (Theorem 7-14) give

$$\begin{aligned}
 0 &= \sum_{s=n+1}^{n+k} \text{II}^s(Y, W) \beta_s^r(X) - \text{II}^s(X, W) \beta_s^r(Y) \quad r > n + k \\
 &\Downarrow \\
 (1) \quad 0 &= \sum_{s=n+1}^{n+k} \beta_s^r(X) \cdot A_{v_s}(Y) - \beta_s^r(Y) \cdot A_{v_s}(X) \quad r > n + k.
 \end{aligned}$$

By assumption, there are $X, Y \in M_p$ such that the vectors $A_{v_s}(X), A_{v_s}(Y)$ for $s = n + 1, \dots, n + k$ are linearly independent. Then (1) shows that

$$(2) \quad \beta_s^r(X) = \beta_s^r(Y) = 0 \quad n + 1 \leq s \leq n + k, \quad r > n + k.$$

Moreover, for any $Z \in M_p$ and $r > n + k$ we have

$$\begin{aligned}
 0 &= \sum_{s=n+1}^{n+k} \beta_s^r(X) \cdot A_{v_s}(Z) - \beta_s^r(Z) \cdot A_{v_s}(X) \\
 &= - \sum_{s=n+1}^{n+k} \beta_s^r(Z) \cdot A_{v_s}(X) \quad \text{by (2)} \\
 &\Downarrow \\
 (3) \quad \beta_s^r(Z) &= 0 \quad n + 1 \leq s \leq n + k, \quad r > n + k.
 \end{aligned}$$

This shows that $D_Z v^s \in \text{Nor}^1 M_p$ for $n + 1 \leq s \leq n + k$, and proves the first part of the theorem.

Now consider the $(n + k)$ -dimensional distribution $\Delta(p) = M_p \oplus \text{Nor}^1 M_p$ along M . The first part of the theorem clearly implies that $\nabla'_Z \xi \in \Delta(p)$ for all sections ξ of Δ and $Z \in M_p$. So Δ is parallel along any curve c , by Pre-Lemma 7-7. The result then follows from Corollary 7-11. ♦

Remark: A curve in \mathbb{R}^m with $\kappa_1, \dots, \kappa_m$ all non-zero represents a counterexample to Lemma 28 when the type number is < 2 .

The extension of Theorem 1 of this chapter to submanifolds of higher codimension rests on some more algebraic results.

29. LEMMETTE. Let $\phi_r, \psi_r, \bar{\phi}_r, \bar{\psi}_r \in V^*$ for $r = 1, \dots, k$ with

$$\sum_{r=1}^k \phi_r \wedge \psi_r = \sum_{r=1}^k \bar{\phi}_r \wedge \bar{\psi}_r.$$

Suppose that $\phi_1, \dots, \phi_k, \psi_1, \dots, \psi_k$ are linearly independent. Then the same is true of the $\bar{\phi}_r, \bar{\psi}_r$, and the subspace $[\phi_1, \dots, \phi_k, \psi_1, \dots, \psi_k]$ spanned by the ϕ_r and ψ_r equals the subspace $[\bar{\phi}_1, \dots, \bar{\phi}_k, \bar{\psi}_1, \dots, \bar{\psi}_k]$ spanned by the $\bar{\phi}_r$ and $\bar{\psi}_r$.

PROOF. Recall that for $v \in V$ and $\omega \in \Omega^k(V)$ we define $v \lrcorner \omega \in \Omega^{k-1}(V)$ by $v \lrcorner \omega(v_1, \dots, v_{k-1}) = \omega(v, v_1, \dots, v_{k-1})$. Define a map $f: V \rightarrow V^*$ by

$$f(v) = v \lrcorner \left(\sum_{r=1}^k \phi_r \wedge \psi_r \right) = \sum_{r=1}^k \phi_r(v) \cdot \psi_r - \psi_r(v) \cdot \phi_r.$$

Clearly

$$\text{range } f \subset [\phi_1, \dots, \phi_k, \psi_1, \dots, \psi_k].$$

Moreover, by linear independence of the ϕ_r and ψ_r , there is $v \in V$ with $\phi_1(v) = 1$ and all other $\phi_r(v) = \psi_r(v) = 0$. Then $f(v) = \psi_1$, so $\psi_1 \in \text{range } f$. Similarly, all $\phi_r, \psi_r \in \text{range } f$, and we therefore have

$$\text{range } f = [\phi_1, \dots, \phi_k, \psi_1, \dots, \psi_k].$$

Now we also have

$$f(v) = \sum_{r=1}^k \bar{\phi}_r(v) \cdot \bar{\psi}_r - \bar{\psi}_r(v) \cdot \bar{\phi}_r.$$

So

$$[\phi_1, \dots, \phi_k, \psi_1, \dots, \psi_k] = \text{range } f \subset [\bar{\phi}_1, \dots, \bar{\phi}_k, \bar{\psi}_1, \dots, \bar{\psi}_k].$$

Hence the subspace on the right has dimension $\geq 2k$. So it has dimension exactly $2k$, which means that the $\bar{\phi}_r, \bar{\psi}_r$ are linearly independent and that the two subspaces are equal. ♦

30. LEMMA (CHERN). Let $S_1, \dots, S_k, \bar{S}_1, \dots, \bar{S}_k$ be symmetric $n \times n$ matrices, with S_1, \dots, S_k linearly independent, of type number ≥ 3 . Suppose that the sum of the determinants of corresponding 2×2 submatrices of the S_r always equals the sum of the determinants of the corresponding 2×2 submatrices of the \bar{S}_r . Then we have

$$\bar{S}_r = \sum_{s=1}^k A_{sr} S_s$$

for some *orthogonal* matrix $A \in O(k)$.

PROOF. Let $T_r, \bar{T}_r: \mathbb{R}^n \rightarrow \mathbb{R}^n$ be the linear transformations with matrices S_r, \bar{S}_r . The hypothesis on the determinants of S_r, \bar{S}_r is equivalent to the hypothesis that the maps

$$T_r^*, \bar{T}_r^*: \Omega^2(\mathbb{R}^n) \rightarrow \Omega^2(\mathbb{R}^n)$$

satisfy

$$\sum_{r=1}^k T_r^* = \sum_{r=1}^k \bar{T}_r^*;$$

in other words, for all $\phi_i, \phi_j \in V^*$ we have

$$(1) \quad \sum_{r=1}^k T_r^*(\phi_i) \wedge T_r^*(\phi_j) = \sum_{r=1}^k \bar{T}_r^*(\phi_i) \wedge \bar{T}_r^*(\phi_j).$$

Choose a basis $\{\phi_i\}$ for V^* such that the $3k$ vectors $\{T_r^*(\phi_i) : i = 1, 2, 3\}$ are linearly independent. Applying (1) with $i = 1, j = 2$, and using the Lemmette, we see that each $\bar{T}_r^*(\phi_1)$ is a linear combination of the $T_s^*(\phi_1), T_s^*(\phi_2)$. Similarly, each $\bar{T}_r^*(\phi_1)$ is a linear combination of the $T_s^*(\phi_1), T_s^*(\phi_3)$. So each $\bar{T}_r^*(\phi_1)$ is a linear combination of the $T_s^*(\phi_1)$. The analogous conclusions hold for the $\bar{T}_r^*(\phi_2)$ and the $\bar{T}_r^*(\phi_3)$. Set

$$\bar{T}_r^*(\phi_1) = \sum_s B_{rs} T_s^*(\phi_1)$$

$$\bar{T}_r^*(\phi_2) = \sum_s C_{rs} T_s^*(\phi_2)$$

$$\bar{T}_r^*(\phi_3) = \sum_s D_{rs} T_s^*(\phi_3).$$

Equation (1) gives us

$$\begin{cases} B \cdot C^t = I = C \cdot B^t & (i = 1, j = 2 \text{ and } i = 2, j = 1) \\ C \cdot D^t = I = D \cdot C^t & (i = 2, j = 3 \text{ and } i = 3, j = 2) \\ B \cdot D^t = I = D \cdot B^t & (i = 1, j = 3 \text{ and } i = 3, j = 1). \end{cases}$$

These imply that $B = C = D$ and $B \cdot B^t = I$, so that B is orthogonal. Let $\tilde{T}_r: \mathbb{R}^n \rightarrow \mathbb{R}^n$ be the linear transformation with

$$\tilde{T}_r^* = \sum_s B_{sr} T_s^*.$$

Then $\tilde{T}_r^*(\phi_j) = \bar{T}_r^*(\phi_j)$ for $j = 1, 2, 3$. We just have to show that this is also true for $j \geq 4$.

Using (1) and orthogonality of B , we see that

$$\sum_r \bar{T}_r^*(\phi_j) \wedge \bar{T}_r^*(\phi_i) = \sum_r \tilde{T}_r^*(\phi_j) \wedge \tilde{T}_r^*(\phi_i) \quad i = 1, 2, 3$$

and hence

$$\sum_r \{\bar{T}_r^*(\phi_j) - \tilde{T}_r^*(\phi_j)\} \wedge \bar{T}_r^*(\phi_i) = 0 \quad i = 1, 2, 3.$$

The $\bar{T}_r^*(\phi_i)$ are linearly independent, so by Cartan's Lemma (Lemma 1-13 or Problem I.7-11) the $\bar{T}_r^*(\phi_j) - \tilde{T}_r^*(\phi_j)$ are a linear combination of the $\bar{T}_r^*(\phi_i)$ for each $i = 1, 2$. But $\{\bar{T}_r^*(\phi_i) : i = 1, 2\}$ are linearly independent, since $\{T_r^*(\phi_i) : i = 1, 2\}$ are, so we must have $\bar{T}_r^*(\phi_j) - \tilde{T}_r^*(\phi_j) = 0$. ♦

31. THEOREM (ALLENDOERFER). Let M^n and \bar{M}^n be immersed submanifolds of \mathbb{R}^m , and let $\phi: M \rightarrow \bar{M}$ be an isometry. Suppose that the first normal spaces of M and \bar{M} have the same constant dimension k at all points. Suppose, moreover, that the type number is ≥ 3 at all points of M . Then ϕ is the restriction of a Euclidean motion.

PROOF. By Lemma 28, there is no loss of generality in assuming that $m = n+k$, so that the first normal space is the whole normal space. First we will show that ϕ is locally the restriction of a Euclidean motion. Choose an orthonormal moving frame X_1, \dots, X_n in a neighborhood U of p , and let $\bar{X}_i = \phi_* X_i$. Choose orthonormal sections v_{n+1}, \dots, v_m of the normal bundle of M , and $\bar{v}_{n+1}, \dots, \bar{v}_m$ for the normal bundle of \bar{M} . For $q \in U$, define $n \times n$ symmetric matrices S_r , $r = n+1, \dots, m$ by

$$(S_r)_{ij} = \Pi^r(X_i(q), X_j(q)).$$

Define \bar{S}_r similarly, for the point $\phi(q)$. Gauss' equation, in the form given on pg. IV.32, shows that the S_r, \bar{S}_r satisfy the hypotheses of Lemma 30. Thus we see that there is an orthogonal matrix-valued function A on U with

$$\bar{S}_r = \sum_s A_{sr} S_s.$$

Using linear independence of the S_r , and smoothness of the S_r and \bar{S}_r , we see that the A_{sr} vary smoothly with q . Now define new sections $v'_{n+1}, \dots, v'_{n+k}$ of the normal bundle of M by

$$v'_r = \sum_s A_{sr} v_s.$$

Then for the corresponding second fundamental forms we have

$$\begin{aligned}\Pi'^r(X, Y) &= \langle s(X, Y), v'_r \rangle \\ &= \left\langle s(X, Y), \sum_s A_{sr} v_s \right\rangle \\ &= \sum_s A_{sr} \Pi^s.\end{aligned}$$

In particular,

$$\begin{aligned}\Pi'^r(X_i, X_j) &= \sum_s A_{sr} \Pi^s(X_i, X_j) \\ &= \sum_s A_{sr} (S_s)_{ij} \\ &= (\bar{S}_r)_{ij} \\ &= \bar{\Pi}^r(\bar{X}_i, \bar{X}_j).\end{aligned}$$

Theorem 7-19 then shows that ϕ is the restriction of a Euclidean motion on U .

We claim that this Euclidean motion is unique. This is easy to see once we note that since the first normal space is the whole normal space, every normal vector at $p \in M$ is $c''(0)$ for some arclength parameterized curve in M . Having established uniqueness, it is clear that the local result implies the global one. ♦

To be sure, the hypothesis that the type number is ≥ 3 is extremely strong for submanifolds of higher codimension, but Theorem 31 is very likely the best local result obtainable. It is therefore a pleasant surprise to find that there is a global result in this area. To end this chapter, with its vast areas of ignorance, on a more joyful note, we quote the following beautiful recent result of J. C. Moore; the proof is somewhat lengthy, but uses only material which has already been developed here, the only somewhat non-standard result being Corollary 11-6.

THEOREM (J. C. MOORE). If M_1, \dots, M_k are compact connected Riemannian manifolds with M_i of dimension $n_i \geq 2$, then any immersion $\phi: M_1 \times \dots \times M_k \rightarrow \mathbb{R}^{n_1 + \dots + n_k + k}$ is, up to a Euclidean motion, a product of immersions of the M_i as hypersurfaces.

In particular, if the M_i are compact convex surfaces in \mathbb{R}^3 , then $M_1 \times \dots \times M_k$ is rigid in \mathbb{R}^{3k} , though not locally rigid.

ADDENDUM

INFINITESIMAL BENDINGS OF ROTATION SURFACES

We will be dealing with surfaces of revolution obtained by revolving a curve $c(s) = (r(s), s)$ in the (x, z) -plane around the z -axis. Define

$$\gamma(t) = (\cos t, \sin t, 0),$$

so that in time 2π , the curve γ goes once around a unit circle in the (x, y) -plane. Then our rotation surface is given by

$$f(s, t) = r(s) \cdot \gamma(t) + s \cdot e_3,$$

where $e_3 = (0, 0, 1)$. Here $r(s)$ is smooth for $s_0 < s < s_1$, while $r'(s_0) = -\infty$ and $r'(s_1) = +\infty$. Considering for the moment only $s \in (s_0, s_1)$, any vector field Z along f can be written uniquely as a linear combination of the three vectors γ, γ', e_3 , thus

$$Z(s, t) = a(s, t) \cdot \gamma(t) + b(s, t) \cdot \gamma'(t) + c(s, t) \cdot e_3.$$

Now Z is an infinitesimal bending if and only if

$$(1) \quad \langle f_1, Z_1 \rangle = 0, \quad \langle f_2, Z_2 \rangle = 0, \quad \langle f_1, Z_2 \rangle + \langle f_2, Z_1 \rangle = 0.$$

Since

$$\begin{aligned} f_1 &= r' \cdot \gamma + e_3 & f_2 &= r \cdot \gamma' \\ Z_1 &= a_1 \cdot \gamma + b_1 \cdot \gamma' + c_1 e_3 & Z_2 &= (a_2 - b) \gamma + (b_2 + a) \gamma' + c_2 e_3, \end{aligned}$$

equations (1) become

$$\begin{aligned} (2) \quad & r' a_1 + c_1 = 0 \\ & b_2 + a = 0 \\ & r'(a_2 - b) + r b_1 + c_2 = 0. \end{aligned}$$

Since a, b, c must be periodic in t of period 2π , it is natural to look for solutions in terms of Fourier series

$$a(s, t) = \sum_{k=-\infty}^{\infty} e^{ikt} \phi_k(s)$$

$$b(s, t) = \sum_{k=-\infty}^{\infty} e^{ikt} \psi_k(s)$$

$$c(s, t) = \sum_{k=-\infty}^{\infty} e^{ikt} \xi_k(s),$$

where, in order that ϕ_k, ψ_k, ξ_k should be real-valued, we must have

$$(3) \quad \phi_{-k} = \bar{\phi}_k, \quad \psi_{-k} = \bar{\psi}_k, \quad \xi_{-k} = \bar{\xi}_k.$$

For a (complex-valued) solution involving a single k , equations (2) become

$$(4) \quad \begin{aligned} r'(s)\phi_k'(s) + \xi_k'(s) &= 0 \\ ik\psi_k(s) + \phi_k(s) &= 0 \\ r'(s)[ik\phi_k(s) - \psi_k(s)] + r(s)\psi_k'(s) + ik\xi_k(s) &= 0. \end{aligned}$$

Differentiating the third equation, and then using the first two, we obtain

$$(*) \quad r\psi_k'' + (k^2 - 1)r''\psi_k = 0.$$

Conversely, suppose we have a complex-valued function ψ_k satisfying (*). Then the first two equations of (4) can be used to determine ϕ_k and then ξ_k . If we *define* $\phi_{-k}, \psi_{-k}, \xi_{-k}$ by (3), then (4) also holds for $-k$. Thus we will have real-valued solutions

$$\begin{aligned} a(s, t) &= e^{ikt} \phi_k(s) + e^{-ikt} \bar{\phi}_k(s) \\ b(s, t) &= e^{ikt} \psi_k(s) + e^{-ikt} \bar{\psi}_k(s) \\ c(s, t) &= e^{ikt} \xi_k(s) + e^{-ikt} \bar{\xi}_k(s) \end{aligned}$$

of (2). Any finite linear combination of solutions is also a solution.

For $k = 0$, we can solve directly from (4). The first two equations give $\phi_0 = 0$, and then $\xi_0 = \text{constant } A$. Then the third equation gives

$$0 = -r'\psi_0 + r\psi_0' = r^2 \left(\frac{\psi_0}{r} \right)' \implies \psi_0 = Br \quad \text{for some constant } B.$$

Thus we obtain the infinitesimal bending

$$\begin{aligned} Z_0(s, t) &= Br(s) \cdot \gamma'(t) + A \cdot e_3 \\ &= [r(s) \cdot \gamma(t) + s \cdot e_3] \times Be_3 + Ae_3 \\ &= (f(s, t) \times Be_3) + Ae_3, \end{aligned}$$

which is trivial.

For $k = 1$, equation (*) says that ψ_1 is linear. In particular, one possible solution is

$$\psi_1(s) = Cs, \quad C \text{ real.}$$

Then the second equation of (4) gives

$$\phi_1(s) = -iCs,$$

and so the first equation gives $\xi_1(s) = iCr(s) + \text{constant}$; in particular, we can take

$$\xi_1(s) = iCr(s).$$

Then we have

$$\begin{aligned} a(s, t) &= 2 \operatorname{Re} e^{it} (-iCs) = 2Cs \sin t \\ b(s, t) &= 2 \operatorname{Re} e^{it} Cs = 2Cs \cos t \\ c(s, t) &= 2 \operatorname{Re} e^{it} (iCr(s)) = -2Cr(s) \sin t. \end{aligned}$$

This gives the trivial infinitesimal bending

$$\begin{aligned} \frac{1}{2} Z_1(s, t) &= (Cs \sin t) \gamma(t) + (Cs \cos t) \gamma'(t) - (Cr(s) \sin t) e_3 \\ &= [r(s) \cdot \gamma(t) + se_3] \times [-C \sin t \gamma' + C \cos t \gamma] \\ &= f(s, t) \times (C, 0, 0). \end{aligned}$$

Similarly, we can take

$$\psi_1(s) = iCs \quad (C \text{ real}), \quad \phi_1(s) = Cs, \quad \xi_1(s) = -Cr(s),$$

obtaining the infinitesimal bending

$$\begin{aligned} \frac{1}{2} Z_1(s, t) &= [r(s) \cdot \gamma(t) + se_3] \times [-C \cos t \gamma' - C \sin t \gamma] \\ &= f(s, t) \times (0, -C, 0). \end{aligned}$$

Obviously *every* trivial infinitesimal bending is a linear combination of the various infinitesimal bendings Z_0, Z_1 . Since the various Z_k are linearly independent, we see that any solution of (*) for $k \geq 2$ leads to an infinitesimal bending Z which is *not* trivial.

These considerations all hold only for the region $s_0 < s < s_1$, that is, for the surface of revolution minus its two “poles”. Given any infinitesimal bending Z_k obtained as above, we still have to see how it behaves at the poles (one can easily see, for example, that if we had picked $\psi_1(s) = Cs + D$ with $D \neq 0$, then the corresponding solution, although not a trivial infinitesimal bending, would have a singularity at the poles). In order to do this, we consider the functions $\phi_k \circ r^{-1}$, etc., where r^{-1} really denotes two different functions, depending on which pole we are at. To be precise, we note that at either pole $r^{-1}(x)$ makes sense for x in some interval $[0, \varepsilon)$. We extend r^{-1} to a function ρ on $(-\varepsilon, \varepsilon)$ by requiring ρ to be even. We will assume that ρ is analytic at 0 (this is precisely what one needs in order for the surface f to be analytic at the poles). Setting

$$\Phi_k = \phi_k \circ \rho$$

$$\Psi_k = \psi_k \circ \rho$$

$$\Xi_k = \xi_k \circ \rho,$$

and noting that $\rho' = 1/r' \circ \rho$, we find that equations (4) can be written

$$\begin{aligned} \rho'(x)\Xi_k'(x) + \Phi_k'(x) &= 0 \\ (5) \quad ik\Psi_k(x) + \Phi_k(x) &= 0 \\ ik\Phi_k(x) - \Psi_k(x) + x\Psi_k'(x) + ik\rho'(x)\Xi(x) &= 0, \end{aligned}$$

while equation (*) becomes

$$(**) \quad x\rho'(x)\Psi_k''(x) - x\rho''(x)\Psi_k'(x) - (k^2 - 1)\rho''(x)\Psi_k(x) = 0.$$

Now suppose also that $\rho''(0) \neq 0$. Then

$$\rho'(x) = \rho''(0)x[1 + \cdots], \quad \rho''(x) = \rho''(0) \cdot [1 + ***]$$

and we can write our equation as

$$x^2\rho''(0)[1 + \cdots]\Psi_k''(x) - x\rho''(0)[1 + \cdots]\Psi_k'(x) - (k^2 - 1)\rho''(0)[1 + ***]\Psi_k(x) = 0$$

or

$$(***) \quad x^2\Psi_k''(x) + x\alpha(x)\Psi_k'(x) + \beta(x)\Psi_k(x) = 0,$$

where α and β are analytic with

$$\alpha(0) = -1, \quad \beta(0) = 1 - k^2.$$

Now equation (***) has a “singular point” at 0; we cannot put it in the form $\Psi_k''(x) = F(x, \Psi_k(x), \Psi_k'(x))$ near 0, so we cannot apply our standard theorems. However, this singular point is of a very special sort, called a “regular singular point”, and there is a complete theory to cover this situation. It is one of the standard topics in differential equations, which the reader can find, for example, in Whittaker and Watson [1; Chapter 10]. The theory shows that equation (***), or equivalently (**), has two linearly independent solutions near $x = 0$ of the form

$$\begin{aligned} \mu_1(x) &= x^{1+k} \cdot (\text{analytic function}) \\ \mu_2(x) &= x^{1-k} \cdot (\text{analytic function}) + c(\log x) \cdot \mu_1(x), \end{aligned}$$

where the analytic functions in question are non-zero at 0 (but c might be 0). So when $k \geq 2$, we see that (**) always has one solution which is analytic near 0, while any linearly independent solution blows up at zero. If Ψ_k is an analytic solution, so that Ψ_k vanishes up to order $k + 1$ at 0, then the first and second equations of (5) determine functions Φ_k and Ξ_k which vanish up to order $k + 1$ and k , respectively, at 0. So for $k \geq 2$ the infinitesimal bending Z_k then determined by $\phi_k = \Phi_k \circ r$, etc., has the form

$$Z_k(s, t) = r(s)^2 \sigma(r(s), t)$$

for some analytic function σ . Now an analytic parameterization of our rotation surface near a pole is given by

$$\begin{aligned} (x, y) &\mapsto \left(x, y, r^{-1}(\sqrt{x^2 + y^2}) \right) \\ &= f \left(r^{-1}(\sqrt{x^2 + y^2}), \arctan \frac{y}{x} \right). \end{aligned}$$

So if $\tilde{Z}_k(x, y)$ denotes the value of Z_k at this point on the rotation surface, then

$$\tilde{Z}_k(x, y) = (\sqrt{x^2 + y^2})^2 \sigma(\sqrt{x^2 + y^2}, t) = (x^2 + y^2) \sigma(\sqrt{x^2 + y^2}, t).$$

One can easily check that this function is* C^2 at 0.

* If σ involved only even powers of $\sqrt{x^2 + y^2}$, then we would actually have an analytic function. Unfortunately, this can never happen, since equations (5), and the fact that σ is even, shows that Φ, Ψ, Ξ cannot all be even functions.

This analysis holds at each pole, but it will usually happen that the function Ψ_k which is analytic for one choice of $\rho = r^{-1}$ will not be analytic for the other choice. So further analysis is required.

We consider a 1-parameter family of functions r_t which passes continuously from a convex function to non-convex functions. For example, we can determine r_t by the equation

$$(r_t(s)^2 + s^2)^2 + 2t^2(r_t(s)^2 - s^2) = 1 - 2t^2 \quad 0 \leq t^2 < \frac{1}{2}.$$

For $t^2 = 1/2$ we have a lemniscate, and for $t = 0$ we have a circle. For $t^2 \leq 1/3$ the functions are convex.

For a fixed t , which we temporarily suppress, consider equation (*) for $r = r_t$:

$$(*) \quad r\psi_k'' + (k^2 - 1)r''\psi_k = 0.$$

On any (concave) interval where $r'' > 0$ (which exist for $t^2 > 1/3$), there will be a large number of zeros of ψ_k once k is large enough. To prove this we merely choose a subinterval on which $r''/r > \varepsilon > 0$ for some ε , and apply the Sturm Comparison Theorem (Theorem 9-15) to equation (*) and the equation $y'' + (k^2 - 1)\varepsilon y = 0$, which has lots of zeros for large k . Notice that on each of the outer intervals, where $r'' < 0$, the function ψ_k cannot have a positive maximum ($\psi_k > 0$, $\psi_k'' \leq 0$) or a negative minimum, so it cannot have even two zeros. Thus the total number of zeros in $(-1, 1)$ is finite. For $t^2 > 1/3$ we have $r'' < 0$ everywhere on $(-1, 1)$, so ψ_k has at most one zero on $(-1, 1)$. Even for $t^2 = 1/3$ we easily see that ψ_k has at most 2 zeros on $(-1, 1)$. Since ψ_k

is a solution of a second order equation, we must have $\psi_k' \neq 0$ when $\psi_k = 0$ (assuming ψ_k is not the zero function), so ψ_k crosses the axis at each zero, rather than being tangent to it. It follows easily that any function sufficiently close to ψ_k has at least as many zeros as ψ_k .

Now pick some t_0 with $t_0^2 > 1/3$ and a k so large that any solution ψ_{k,t_0} of (*) for $r = r_{t_0}$ has more than 2 zeros on $[0, 1)$. Let ψ_{k,t_0} be a solution which gives an infinitesimal bending that is C^2 at the bottom pole $s = -1$, and let $n_0 > 2$ be the number of its zeros on $[0, 1)$. Now for all $t < t_0$ we will pick a continuous family of solutions $\psi_{k,t}$ of (*) for $r = r_t$, all of which also give infinitesimal bendings that are C^2 at the bottom pole. Choosing $\psi_{k,t}$ is equivalent to choosing $\Psi_{k,t}$, which is determined only up to a constant factor. So we can easily arrange that each $\psi_{k,t}$ is not the zero function. For $t^2 \geq 1/3$, the function $\psi_{k,t}$ has at most two zeros in $(-1, 1)$, so *a fortiori* at most two zeros in $[0, 1)$. So we can consider the greatest lower bound t_1 of all t such that $\psi_{k,t}$ has exactly n_0 zeros on $[0, 1)$, and $t_1^2 > 1/3$.

We claim that ψ_{k,t_1} has a zero at 0. For suppose that all the zeros of ψ_{k,t_1} on $[0, 1)$ actually occur on $(0, 1)$, and let n_1 be the number of such zeros. Since any function sufficiently close to ψ_{k,t_1} has at least as many zeros on $(0, 1)$ as ψ_{k,t_1} does, we easily see that $n_1 \leq n_0$. We claim that we cannot have $n_1 < n_0$. To prove this, it suffices to show that the functions $\psi_{k,t}$ for t close to t_1 have *at most* as many zeros on $(0, 1)$ as ψ_{k,t_1} does. On some interval containing the n_1 zeros of ψ_{k,t_1} we will have $r_{t_1}''/r_{t_1} < M$ for some M . The same inequality holds on this interval for t sufficiently close to t_1 . Applying the (second part of) the Sturm Comparison Theorem to (*) and the equation $y'' + (k^2 - 1)My = 0$, we find that the zeros of $\psi_{k,t}$ must be at least $\varepsilon = \pi / \sqrt{(k^2 - 1)M}$ apart. So if we choose a neighborhood of the graph of ψ_{k,t_1} which intersects the s -axis in intervals of length $< \varepsilon$, then the $\psi_{k,t}$ whose graphs lie in this neighborhood

can have at most n_1 zeros on $(0, 1)$. Thus we have shown that ψ_{k,t_1} actually has exactly n_0 zeros on $(0, 1)$.

But these very same arguments show that for t sufficiently close to t_1 , the function $\psi_{k,t}$ has exactly n_0 zeros on $[0, 1)$ *even for* $t < t_1$. This contradicts the choice of t_1 , and thus shows that indeed $\psi_{k,t_1}(0) = 0$.

Now from the differential equation

$$r_{t_1} \psi_{k,t_1}'' + (k^2 - 1) r_{t_1}'' \psi_{k,t_1} = 0$$

satisfied by ψ_{k,t_1} , and the fact that r_{t_1} is an even function, we easily see that $s \mapsto \psi_{k,t_1}(-s)$ also satisfies the equation. Since $\psi_{k,t_1}(0) = 0$, it follows that $\psi_{k,t_1}(-s) = c \cdot \psi_{k,t_1}(s)$ for some constant c . But this means that the infinitesimal bending determined by ψ_{k,t_1} [on the rotation surface determined by r_{t_1}] is also C^2 at the top pole.

PROBLEMS

1. Let $\alpha, \beta: \mathbb{R} \rightarrow \mathbb{R}^2$ be differentiable functions for which we know the functions

$$\langle \alpha, \beta \rangle, \quad \langle \alpha', \beta \rangle, \quad \langle \alpha, \alpha \rangle, \quad \langle \beta, \beta \rangle,$$

We want to show that we can find α and β once we know $\alpha(0)$ and $\beta(0)$.

(a) We can assume that $\langle \alpha, \alpha \rangle = \langle \beta, \beta \rangle = 1$.

(b) If we write

$$\begin{aligned}\alpha(x) &= (\cos \theta(x), \sin \theta(x)) \\ \beta(y) &= (\cos \phi(y), \sin \phi(y)),\end{aligned}$$

then $\langle \alpha, \beta \rangle$ and $\langle \alpha', \beta \rangle$ determine θ' . Hence $\alpha(0)$ determines α .

(c) Then $\beta(0)$ determines β .

2. (a) Let η be a 1-parameter family of k -forms. Use Proposition 9-10 to show that for every singular $(k+1)$ -cube c we have

$$\int_c (d\eta)^\cdot = \int_{\partial c} \dot{\eta} = \int_c d\dot{\eta}.$$

Conclude that $(d\eta)^\cdot = d\dot{\eta}$.

(b) Give another proof by writing $\eta(u)$ in a coordinate system x^1, \dots, x^n , and noting that $\partial/\partial u$ commutes with $\partial/\partial x^j$.

3. A surface $M \subset \mathbb{R}^3$ is called **isothermal** if it can be covered by isothermal coordinate systems whose parameter lines lie along the lines of curvature.

(a) Surfaces of revolution are isothermal.

(b) Problem 4-8 shows that ellipsoids and hyperboloids of one or two sheets have coordinate systems (u, v) with

$$\langle \ , \ \rangle = (u - v) \left[\frac{u}{f(u)} du \otimes du - \frac{v}{f(v)} dv \otimes dv \right],$$

where the u - and v -parameter lines are lines of curvature. Conclude that these surfaces are isothermal.

(c) Let X_1, X_2 be a moving frame consisting of orthonormal principal vectors. Show that M is isothermal if and only if there is a nowhere zero function α such that

$$d\alpha \wedge \theta^1 + \alpha \omega_1^2 \wedge \theta^2 = 0 = d\alpha \wedge \theta^2 - \alpha \omega_1^2 \wedge \theta^1.$$

Hint: This means that $d(u\theta^1) = d(u\theta^2) = 0$.

4. Let $M \subset \mathbb{R}^3$ be a surface, and $\alpha: [0, 1] \times M \rightarrow \mathbb{R}^3$ a variation as on page 225.

(a) Show that

$$\dot{\psi}_1^3 \wedge \psi_2^3 + \psi_1^3 \wedge \dot{\psi}_2^3 = 0$$

$$d\dot{\psi}_1^3 = \omega_1^2 \wedge \dot{\psi}_2^3$$

$$d\dot{\psi}_2^3 = -\omega_1^2 \wedge \dot{\psi}_1^3.$$

(b) Show that $\dot{H} = 0$ if and only if

$$\dot{\psi}_1^3 \wedge \theta^2 = \dot{\psi}_2^3 \wedge \theta^1.$$

Hint: Use the equation on pg. III.69.

(c) Suppose that the moving frame X_1, X_2 on M consists of principal vectors, so that $\psi_i^3 = k_i \theta^i$, where k_1, k_2 are the principal curvatures. If p is an umbilic, then we always have $\dot{H}(p) = 0$. [*Hint:* Use the first equation of (a).] On the other hand, if $\dot{H} = 0$, and M has no umbilics, then

$$\dot{\psi}_1^3 \wedge \theta^2 = 0 = \dot{\psi}_2^3 \wedge \theta^1.$$

(d) If we write

$$\psi_i^3(t) = \sum_j l_{ij}(t) \theta^j(t), \quad l_{11}(0) = k_1, \quad l_{22}(0) = k_2,$$

then $\dot{H} = 0 \implies \dot{l}_{11} = \dot{l}_{22} = 0$.

(e) Conclude that if $\dot{H} = 0$, then

$$d\dot{l}_{12} \wedge \theta^1 - 2\dot{l}_{12}\omega_2^1 \wedge \theta^1 = 0$$

$$d\dot{l}_{12} \wedge \theta^2 - 2\dot{l}_{12}\omega_1^2 \wedge \theta^1 = 0.$$

Then use **Problem 3** to show that M is isothermal.

5. For vectors v_1, \dots, v_{n-1} and w_1, \dots, w_{n-1} in \mathbb{R}^n , show that

$$\langle v_1 \times \cdots \times v_{n-1}, w_1 \times \cdots \times w_{n-1} \rangle = \det(\langle v_i, w_j \rangle)$$

by noting that both sides are linear in the v_i and w_j .

CHAPTER 13

THE GENERALIZED GAUSS-BONNET THEOREM AND WHAT IT MEANS FOR MANKIND

In previous chapters we have seen that interesting and challenging questions can arise even in the lowest dimensions, and that the methods used to resolve these problems often rely more on ingenuity and hard work than on particularly sophisticated concepts—the proofs may be involved, but they have the satisfying concreteness of geometrical arguments, and something of the charm of antique music. Nevertheless, it is futile to deny the decisive influence which has been wrought upon the shape of modern mathematics by the daemonic spirit of functorial constructions. So it is appropriate that this book end with a topic that represents one of the triumphs of machinery in mathematics. Here, at last, connections in principal bundles play their true predestined role, the invariant form of the Bianchi identities prove their superiority, and connections on arbitrary bundles are frequently invoked. As a final affirmation that we have plunged into the icy stream of modern mathematics, hardly a picture appears.

One of the star attractions of differential geometry is the Gauss-Bonnet Theorem, which for a compact oriented surface M states that

$$\int_M K \, dA = 2\pi \chi(M).$$

Although the curvature K is defined intrinsically in terms of the metric $\langle \cdot, \cdot \rangle$ on M , it can also be defined extrinsically when the metric $\langle \cdot, \cdot \rangle$ on M is induced by an imbedding $M \subset \mathbb{R}^3$. In fact, if $\nu: M \rightarrow S^2$ is the normal map, and da is the volume element of S^2 , then $K \, dA = \nu^*(da)$, so that

$$\int_M K \, dA = \int_M \nu^*(da) = (\deg \nu) \cdot \int_{S^2} da = 4\pi \cdot (\deg \nu).$$

As we indicated in Addendum 2 to Chapter 6, one can prove, without invoking any differential geometry, that $\deg \nu = \frac{1}{2}\chi(M)$, thus proving the Gauss-Bonnet Theorem for the special case where the metric on M comes from an imbedding in \mathbb{R}^3 . Precisely this argument was used by Heinz Hopf [2] in obtaining the

first generalization of the Gauss-Bonnet Theorem. Consider a compact hypersurface $M^n \subset \mathbb{R}^{n+1}$, where n is even. If da denotes the volume element of S^n , then

$$\begin{aligned} \int_M K_n dV &= \int_M \nu^*(da) = (\text{volume of } S^n) \cdot \deg \nu \\ &= \frac{(\text{volume of } S^n)}{2} \cdot \chi(M), \quad \text{by Corollary 6-23.} \end{aligned}$$

Now this result, although proved for a hypersurface of \mathbb{R}^{n+1} , can be formulated for any compact oriented Riemannian n -manifold $(M, \langle \cdot, \cdot \rangle)$ of even dimension n . In fact, we have already noted (pg. IV.69) that

$$(*) \quad K_n = \frac{1}{2^{n/2} n!} \cdot \text{contraction of } \underbrace{(\mathbb{R} \otimes \cdots \otimes \mathbb{R})}_{n/2 \text{ times}} \otimes \mathfrak{E} \otimes \mathfrak{E}.$$

In a coordinate system, we have (pg. IV.69)

$$K_n = \frac{1}{2^{n/2} n!} \sum_{\substack{i_1, \dots, i_n \\ j_1, \dots, j_n}} R_{i_1 i_2 j_1 j_2} \cdots R_{i_{n-1} i_n j_{n-1} j_n} \cdot \frac{\varepsilon^{i_1 \dots i_n}}{\sqrt{\det(g_{ij})}} \cdot \frac{\varepsilon^{j_1 \dots j_n}}{\sqrt{\det(g_{ij})}}.$$

We are thus led to conjecture that we always have

$$\int_M K_n dV = \frac{(\text{volume of } S^n)}{2} \cdot \chi(M),$$

whenever M is a compact oriented Riemannian manifold with n even, where K_n is defined by (*).

For the case where the metric on M comes from an imbedding $M \subset \mathbb{R}^{n+k}$ in some Euclidean space, the result was first proved by Allendoerfer [1] and Fenchel [2]. This was done by considering a closed tubular neighborhood N of M , for which $\partial N \subset \mathbb{R}^{n+k}$ is a hypersurface with a volume element dV , say, and corresponding K_{n+k-1} . We can assume that $n+k-1$ is even (by considering $M \subset \mathbb{R}^{n+k} \subset \mathbb{R}^{n+k+1}$ if necessary), so that the result for hypersurfaces gives

$$\int_{\partial N} K_{n+k-1} dV = \frac{(\text{volume of } S^{n+k-1})}{2} \cdot \chi(\partial N).$$

Now it can be shown without too much difficulty that

$$\chi(\partial N) = \chi(M) \cdot \chi(S^{k-1}) = 2\chi(M).$$

On the other hand, it also works out that

$$\int_{\partial N} \mathbf{K}_{n+k-1} dV$$

can be computed in terms of $\int_M K_n dV$; when the computation is effected, we obtain the correct expression for $\int_M K_n dV$.

At the time of this proof, the Nash imbedding theorem was not yet known. But the Burstin-Janet-Cartan Theorem (Theorem 11-9) was known. In 1943, Allendoerfer and Weil [1] proved a generalization of the Gauss-Bonnet formula for a polyhedral piece of a Riemannian manifold imbedded in Euclidean space; using this, they were able to obtain a proof of the general Gauss-Bonnet Theorem for (C^ω) Riemannian manifolds, by means of a triangulation. Since the Nash imbedding theorem is now available, the earlier result of Allendoerfer and Fenchel implies that the generalized Gauss-Bonnet Theorem holds for all C^∞ manifolds. But a proof of this sort is clearly unsatisfactory, not only because of the difficulty and essentially non-differential geometric nature of Nash's result, but also because an intrinsic theorem ought to have an intrinsic proof. The intrinsic proof was obtained by Chern [2] in 1944. Ensuing developments have led to a much deeper understanding of the fundamentals which are involved here, so that we can now give a completely non-computational proof of this extraordinary theorem. This proof by magic is presented in the first four sections; in the remainder of the Chapter we will contravene the rules of legerdemain, and reveal some of the mechanism behind it.

1. OPERATIONS ON BUNDLES

In the past we have considered numerous structures on vector bundles and principal bundles, but, except in some of the problems for Chapter I.3, we have not yet examined in detail the relationships between different bundles. The simplest relation is that of equivalence \simeq between two vector bundles ξ_1 and ξ_2 over the same base space X . We have also defined the notion of a bundle map from $\xi_1 = \pi_1: E_1 \rightarrow X_1$ to $\xi_2 = \pi_2: E_2 \rightarrow X_2$. This is a pair of continuous maps (\tilde{f}, f) , where $f: X_1 \rightarrow X_2$ and $\tilde{f}: E_1 \rightarrow E_2$; the map \tilde{f} is required to satisfy $\pi_2 \circ \tilde{f} = f \circ \pi_1$, so that \tilde{f} takes fibres of ξ_1 to fibres of ξ_2 , and each map $\tilde{f}: \pi_1^{-1}(x) \rightarrow \pi_2^{-1}(f(x))$ is required to be linear. In this chapter we will redefine the notion of a **bundle map**, by adding the requirement that each $\tilde{f}: \pi_1^{-1}(x) \rightarrow \pi_2^{-1}(f(x))$ be an isomorphism of vector spaces (so ξ_1

and ξ_2 must have the same fibre dimension). Instead of referring to a bundle map (\tilde{f}, f) , we will often say that \tilde{f} is a **bundle map covering** f . If \tilde{f} is a bundle map covering a homeomorphism $f: X_1 \rightarrow X_2$ from X_1 onto X_2 , then we can define $(\tilde{f})^{-1}: E_2 \rightarrow E_1$. Using the local product structure, and the fact that $A \mapsto A^{-1}$ is continuous for $A \in \text{GL}(n, \mathbb{R})$, we easily see that $(\tilde{f})^{-1}$ is continuous, so that $(\tilde{f})^{-1}$ is a bundle map covering f^{-1} . In particular, a bundle map covering the identity map of X is an equivalence.

Consider next two principal bundles $\xi_i = \pi_i: P_i \rightarrow X_i$ ($i = 1, 2$) with the same group G ; we denote the action of G on the right of P_1 and P_2 by the same symbol “ \cdot ”. A **(principal) bundle map** from ξ_1 to ξ_2 is a pair (\tilde{f}, f) , where $f: X_1 \rightarrow X_2$ and $\tilde{f}: P_1 \rightarrow P_2$, such that $\pi_2 \circ \tilde{f} = f \circ \pi_1$, and such that

$$(*) \quad \tilde{f}(u \cdot a) = \tilde{f}(u) \cdot a \quad \text{for all } u \in P \text{ and } a \in G.$$

Notice that condition $(*)$ already implies that \tilde{f} takes fibres to fibres, and thus automatically gives us the map f . We could thus speak simply of a bundle map \tilde{f} . In practice, it is usually more convenient to speak of a **bundle map \tilde{f} covering f** . Note also that $\tilde{f}: \pi_1^{-1}(x) \rightarrow \pi_2^{-1}(f(x))$ is clearly a homeomorphism, since the fibres of P_1 are $\{u \cdot a : a \in G\}$ for fixed u , and similarly for the fibres of P_2 . As before, if \tilde{f} is a bundle map over a homeomorphism $f: X_1 \rightarrow X_2$, then $(\tilde{f})^{-1}$ is a bundle map over f^{-1} . When f is the identity map of X , we call \tilde{f} an **equivalence**, or an **isomorphism**. A principal bundle $\xi = \pi: P \rightarrow X$ is called **trivial** if it is equivalent to the bundle $\pi': X \times G \rightarrow X$, where π' is projection on the first coordinate. As we have already pointed out (pg. II.311), if the principal bundle ξ has a section $s: X \rightarrow P$, then ξ is trivial, for we can define a map $X \times G \rightarrow P$ by $(x, a) \mapsto s(x) \cdot a$.

Recall (pg. II.307) that for every n -dimensional vector bundle $\xi = \pi: E \rightarrow X$ we can define the principal bundle $F(\xi) = \varpi: F(E) \rightarrow X$ of frames of E , with group $\text{GL}(n, \mathbb{R})$, whose fibre $\varpi^{-1}(x)$ is the set of all ordered bases (u_1, \dots, u_n) of the vector space $\pi^{-1}(x)$. If ξ_i are vector bundles over X_i and $\tilde{f}: E_1 \rightarrow E_2$ is a bundle map covering $f: X_1 \rightarrow X_2$, then we clearly have also a principal bundle map $\tilde{f}: F(E_1) \rightarrow F(E_2)$ covering f (this would not be true if we did not require a bundle map to be an isomorphism on each fibre). Conversely, a principal bundle map $\tilde{f}: F(E_1) \rightarrow F(E_2)$ covering f gives rise to a bundle map $\tilde{f}: E_1 \rightarrow E_2$. In fact, given any frame $u = (u_1, \dots, u_n)$ of $\pi_1^{-1}(x)$, there is a unique isomorphism $\pi_1^{-1}(x) \rightarrow \pi_2^{-1}(f(x))$ which takes u_i to the i^{th} member of the frame of $\tilde{f}(u)$. The condition $(*)$ on \tilde{f} insures that this isomorphism is well-defined.

There is one operation which is special for vector bundles. Given two vector bundles $\xi_i = \pi_i: E_i \rightarrow X$ over the same space X , we can form the direct sum $\pi_1^{-1}(x) \oplus \pi_2^{-1}(x)$ [= $\pi_1^{-1}(x) \times \pi_2^{-1}(x)$ as a set] for each $x \in X$. Let

$$E = \bigcup_{x \in X} \pi_1^{-1}(x) \times \pi_2^{-1}(x) \subset E_1 \times E_2,$$

with the topology it has as a subset of $E_1 \times E_2$, and let $\pi: E \rightarrow X$ be the map which takes all elements of $\pi_1^{-1}(x) \times \pi_2^{-1}(x)$ to x (thus $\pi = \pi_i|_E$ for $i = 1, 2$). It is easy to check that $\pi: E \rightarrow X$ is also a vector bundle, whose fibre dimension is the sum of the fibre dimensions of ξ_1 and ξ_2 . This new bundle is called the **Whitney sum** $\xi_1 \oplus \xi_2$ of ξ_1 and ξ_2 . We clearly have

$$\xi_1 \oplus \xi_2 \simeq \xi_2 \oplus \xi_1, \quad (\xi_1 \oplus \xi_2) \oplus \xi_3 \simeq \xi_1 \oplus (\xi_2 \oplus \xi_3).$$

Our next construction works for either a vector bundle or a principal bundle $\xi = \pi: E \rightarrow Y$. Let $f: X \rightarrow Y$ be continuous. We can construct a

$$\begin{array}{ccc} & E & \\ & \downarrow \pi & \\ X & \xrightarrow{f} & Y \end{array}$$

[principal] bundle η over X , and a [principal] bundle map (\tilde{f}, f) from η to ξ , as follows.

$$\begin{array}{ccccc} X \times E \supset E' & \xrightarrow{\tilde{f}} & E & & \\ \downarrow \pi' & & \downarrow \pi & & \\ X & \xrightarrow{f} & Y & & \end{array}$$

Let

$$E' \subset X \times E = \{(x, e) : f(x) = \pi(e)\},$$

and let

$$\pi': E' \rightarrow X \quad \text{be} \quad \pi'((x, e)) = x.$$

Thus the fibre $\pi'^{-1}(x)$ over a point $x \in X$ is just $\{x\} \times \pi^{-1}(f(x))$. In the case of a vector bundle, we use the vector space structure on $\pi^{-1}(f(x))$ to define a vector space structure on $\pi'^{-1}(x)$; in the case of a principal bundle, we use the action of G on $\pi^{-1}(f(x))$ to define the action of G on $\pi'^{-1}(x)$. It is easy to check that $\pi': E' \rightarrow X$ is a vector bundle [principal bundle], and that $\tilde{f}: E' \rightarrow E$ defined by

$$\tilde{f}((x, e)) = e$$

is a [principal] bundle map covering f . The bundle $\pi': E' \rightarrow X$ is denoted by $f^*\xi$, and is called the bundle over X **induced** by f and ξ . If $X \subset Y$ and $i: X \rightarrow Y$ is the inclusion map, then $i^*\xi$ is equivalent to the restriction $\xi|_X$ of ξ to X . If $g: W \rightarrow X$ is another continuous map, then

$$g^*(f^*\xi) \simeq (f \circ g)^*(\xi).$$

Finally, if $\xi = \pi: E \rightarrow Y$ is a vector bundle, then

$$f^*(F(\xi)) \simeq F(f^*\xi).$$

Although we used an explicit construction to define $f^*\xi$, this [principal] bundle can be characterized uniquely, up to equivalence, by the fact that there is a [principal] bundle map covering f from $f^*\xi$ to ξ . Indeed, suppose that $\eta = \pi'': E'' \rightarrow X$ is a [principal] bundle, and $\tilde{f}: E'' \rightarrow E$ is a [principal] bundle map covering f . We define $g: E'' \rightarrow E'$ by

$$g(e'') = (f(\pi''(e'')), \tilde{f}(e''));$$

it is easily seen that g is an equivalence of η and $f^*\xi$.

In the case of two vector bundles $\xi_i = \pi_i: E_i \rightarrow Y$ we have

$$f^*(\xi_1 \oplus \xi_2) \simeq f^*(\xi_1) \oplus f^*(\xi_2).$$

The most reasonable way to prove this is to consider the explicit construction of the total space E of $f^*(\xi_1) \oplus f^*(\xi_2)$, and then define a bundle map \tilde{f} covering f from E to the total space of $\xi_1 \oplus \xi_2$. On the other hand, consider two bundles $\xi_i = \pi_i: E_i \rightarrow X_i$, and let $p_i: X_1 \times X_2 \rightarrow X_i$ be the projections on the factors. Then we can form the bundle

$$\xi_1 \times \xi_2 = p_1^*(\xi_1) \oplus p_2^*(\xi_2)$$

over $X_1 \times X_2$; the fibre over (x_1, x_2) is essentially $\pi_1^{-1}(x_1) \oplus \pi_2^{-1}(x_2)$. When $X_1 = X_2 = X$, we have

$$\xi_1 \oplus \xi_2 \simeq \Delta^*(\xi_1 \times \xi_2),$$

where $\Delta: X \rightarrow X \times X$ is the diagonal map, $\Delta(x) = (x, x)$.

As a somewhat more esoteric example of induced bundles, consider a vector bundle $\xi = \pi: E \rightarrow X$ with a Riemannian metric $\langle \cdot, \cdot \rangle$. Let S be the “sphere bundle”

$$S = \{e \in E : \langle e, e \rangle = 1\},$$

and denote the restriction $\pi|_S$ by $\pi_0: S \rightarrow X$. Then we can form the bundle $\pi_0^*\xi$ over S . We claim that $\pi_0^*\xi$ *always has a nowhere zero section*. To see this, we recall the construction of $\pi_0^*\xi$. For each $e \in S$, the fibre of $\pi_0^*\xi$ over e is just

$$\{e\} \times \pi^{-1}(\pi_0(e)) = \{e\} \times \pi^{-1}(\pi(e)).$$

We define a section s of $\pi_0^*\xi$ by

$$s(e) = (e, e) \in \{e\} \times \pi^{-1}(\pi(e)).$$

Since

$$s(e) \neq (e, 0) = 0 \text{ element of fibre of } \pi_0^*\xi \text{ over } e,$$

this section s is indeed nowhere zero. Similarly, if we regard X as a subspace of E (by considering X as the image of the 0 section), then the induced bundle $(\pi|_{E-X})^*\xi$ over $E-X$ has a nowhere zero section. On the other hand, the bundle $\pi^*\xi$ itself need not have such a section. Indeed, if it does, then the restriction $(\pi^*\xi)|_X$ of $\pi^*\xi$ to X must have a nowhere zero section. But it is clear that $(\pi^*\xi)|_X \simeq \xi$.

The most important result about induced bundles gives a condition under which $f^*\xi \simeq g^*\xi$. As a start towards this result, we note that *any* bundle over $[0, 1]$ is trivial. The proof may be considered as an exercise for the reader; the next Lemma and Theorem establish a more general result.

1. LEMMA. Let ξ be a principal bundle over $X \times [a, b]$. Then every point $x \in X$ has a neighborhood U such that ξ is trivial over $U \times [a, b]$.

PROOF. Each point $(x, t) \in \{x\} \times [a, b]$ has a neighborhood $V \times W$ such that ξ is trivial over $V \times W$. By compactness, finitely many such neighborhoods $V_1 \times W_1, \dots, V_r \times W_r$ cover $\{x\} \times [a, b]$. We claim that the theorem holds with $U = V_1 \cap \dots \cap V_r$. The proof will be by induction on r . For $r = 1$ it is trivial. Assume it holds for $\leq r - 1$ sets. We can clearly choose a point $t_0 \in (a, b)$ such that $[a, t_0]$ and $[t_0, b]$ are each covered by $\leq r - 1$ of the sets $V_i \times W_i$. Then ξ is trivial over sets $U_1 \times [a, t_0]$ and $U_2 \times [t_0, b]$. This means that there is a section s of ξ over $U_1 \times [a, t_0]$ and a section σ of ξ over $U_2 \times [t_0, b]$. On $(U_1 \cap U_2) \times \{t_0\}$ we have

$$s(x, t_0) = \sigma(x, t_0) \cdot a(x)$$

for a continuous function $x \mapsto a(x) \in G$. Then we can define a section \bar{s} on $(U_1 \cap U_2) \times [a, b]$ by

$$\bar{s}(x, t) = \begin{cases} s(x, t) & a \leq t \leq t_0 \\ \sigma(x, t) \cdot a(x) & t_0 \leq t \leq b. \end{cases} \blacklozenge$$

Now let $j: X \times \{1\} \rightarrow X \times [0, 1]$ be the inclusion, and let $p: X \times [0, 1] \rightarrow X \times \{1\}$ be $p(x, t) = (x, 1)$.

2. THEOREM. If $\xi = \pi: P \rightarrow X \times [0, 1]$ is a principal bundle, and X is paracompact, then

$$\xi \simeq p^* j^* \xi \simeq p^*(\xi|X \times \{1\}).$$

PROOF. We want to show that there is a bundle map $\tilde{p}: P \rightarrow \pi^{-1}(X \times \{1\})$ covering p .

$$\begin{array}{ccc} P & \xrightarrow{\tilde{p}} & \pi^{-1}(X \times \{1\}) \\ \downarrow & & \downarrow \\ X \times [0, 1] & \xrightarrow{p} & X \times \{1\} \end{array}$$

By Lemma 1, there is an open cover $\{U_\alpha\}$ of X such that ξ is trivial on $U_\alpha \times [0, 1]$. We can assume that $\{U_\alpha\}$ is locally finite, by taking a refinement if necessary. By Theorem I.2-15 we can choose a partition of unity $\{\phi_\alpha\}$ with support $\phi_\alpha \subset U_\alpha$ (the Theorem is stated for a manifold, but holds for any normal space X if we only want the functions ϕ_α to be continuous). Let s_α be a section of ξ over $U_\alpha \times [0, 1]$. Consider the map, from $\pi^{-1}(U_\alpha \times [0, 1])$ to itself, defined by

$$s_\alpha(x, t) \mapsto s_\alpha(x, \min(t + \phi_\alpha(x), 1)).$$

This map is the identity on $(\text{boundary } U_\alpha) \times [0, 1]$. So we can extend it continuously to $X \times [0, 1]$ by making it the identity on $(X - U_\alpha) \times [0, 1]$. Thus we obtain a map

which is a bundle map from ξ to the part of ξ over the shaded set in the figure.

Suppose first that there are at most countably many such maps, $\tilde{p}_1, \tilde{p}_2, \dots$. Define

$$\tilde{p} = \tilde{p}_1 \circ \tilde{p}_2 \circ \dots$$

This possibly infinite composition makes sense, since all but finitely many \tilde{p}_i are the identity in a neighborhood of any point. Clearly \tilde{p} is the desired bundle map.

Even if there are uncountably many maps $\{\tilde{p}_\alpha : \alpha \in A\}$, the procedure is the same. Choose any ordering on A (not necessarily a well-ordering) and define \tilde{p} to be the composition of the \tilde{p}_α in the order given by A ; in a neighborhood of any point, only finitely many \tilde{p}_α are not the identity map, so this makes sense. ♦

In practice, it is more convenient to work with a slight restatement, and application, of Theorem 2. Let $i_t : X \rightarrow X \times [0, 1]$ be $i_t(x) = (x, t)$.

3. COROLLARY. If ξ is a principal bundle over $X \times [0, 1]$, and X is paracompact, then

$$i_0^* \xi \simeq i_1^* \xi.$$

PROOF. Let $q : X \times [0, 1] \rightarrow X$ be the projection $q(x, t) = x$. Then $j \circ p = i_1 \circ q$. So, by Theorem 2,

$$(1) \quad \xi \simeq p^* j^* \xi \simeq (j \circ p)^* \xi = (i_1 \circ q)^* \xi \simeq q^* i_1^* \xi.$$

On the other hand, we also have $q \circ i_0 = \text{identity}$. Consequently, equation (1) gives

$$i_0^* \xi \simeq i_0^* q^* i_1^* \xi \simeq [i_1 \circ (q \circ i_0)]^* \xi \simeq i_1^* \xi. \quad \spadesuit$$

From this we immediately obtain the result toward which we have been aiming.

4. THEOREM (THE COVERING HOMOTOPY THEOREM). If η is a principal bundle over Y and $f, g : X \rightarrow Y$ are homotopic, with X paracompact, then $f^* \eta \simeq g^* \eta$. The same result holds if η is a vector bundle.

PROOF. Let $H : X \times [0, 1] \rightarrow Y$ be a map with

$$H \circ i_0 = f \quad \text{and} \quad H \circ i_1 = g.$$

Applying Corollary 3 to $\xi = H^*(\eta)$ over $X \times [0, 1]$, we have

$$\begin{aligned} f^*\eta &= (H \circ i_0)^*\eta \simeq i_0^*(H^*\eta) \\ &\simeq i_1^*(H^*\eta) \simeq (H \circ i_1)^*\eta = g^*\eta. \end{aligned}$$

When η is vector bundle we have, by the remark on page 268,

$$F(f^*\eta) \simeq f^*(F(\eta)) \simeq g^*(F(\eta)) \simeq F(g^*\eta).$$

By the remark on page 266, this implies that $f^*\eta \simeq g^*\eta$. ♦

As a particular case of Theorem 4, note that if X is paracompact and contractible, so that the identity map $1: X \rightarrow X$ is homotopic to a constant map c , then $\xi \simeq 1^*\xi \simeq c^*\xi$, which is trivial. So any principal bundle or vector bundle over X is trivial (compare with remark 3 on pg. I.474).

In applying these results, we will usually be interested only in vector bundles. But in one instance principal bundles will be used. Let $\xi = \pi: E \rightarrow X$ be a vector bundle, and let $\langle \cdot, \cdot \rangle$ be a Riemannian metric on ξ . As in Chapter 7, we can consider the principal bundle $O(\xi) = \varpi: O(E) \rightarrow X$ with group $O(n)$, whose fibre $\varpi^{-1}(x)$ is the set of all frames of $\pi^{-1}(x)$ which are orthonormal with respect to $\langle \cdot, \cdot \rangle$. If $\langle \cdot, \cdot \rangle'$ is another Riemannian metric on ξ , then we have another principal bundle $O'(\xi) = \varpi': O'(E) \rightarrow X$, consisting of frames which are orthonormal with respect to $\langle \cdot, \cdot \rangle'$.

5. COROLLARY. If $\xi = \pi: E \rightarrow X$ is a vector bundle with two Riemannian metrics $\langle \cdot, \cdot \rangle$ and $\langle \cdot, \cdot \rangle'$, then $O(\xi) \simeq O'(\xi)$.

PROOF. Let $q: X \times [0, 1] \rightarrow X$ be the projection $q(x, t) = x$, and consider the bundle $q^*\xi$ over $X \times [0, 1]$. The fibre of $q^*\xi$ over (x, t) is

$$\{(x, t)\} \times \pi^{-1}(x).$$

The inner products $\langle \cdot, \cdot \rangle_x$ and $\langle \cdot, \cdot \rangle'_x$ on $\pi^{-1}(x)$ give us an inner product

$$t\langle \cdot, \cdot \rangle_x + (1-t)\langle \cdot, \cdot \rangle'_x$$

on $\pi^{-1}(x)$. Using this inner product on the fibre $\{(x, t)\} \times \pi^{-1}(x)$, we obtain a Riemannian metric $\langle \cdot, \cdot \rangle$ on $q^*\xi$, and we can consider the corresponding principal bundle $O(q^*\xi)$. If $i_t: X \rightarrow X \times [0, 1]$ is $i_t(x) = (x, t)$, then clearly

$$i_0^* O(q^*\xi) \simeq O(\xi) \quad \text{and} \quad i_1^* O(q^*\xi) \simeq O'(\xi).$$

So the result follows from Corollary 3. ♦

2. GRASSMANNIANS AND UNIVERSAL BUNDLES

We have defined projective n -space \mathbb{P}^n to be the set of all pairs $\{p, -p\}$ for $p \in S^n \subset \mathbb{R}^{n+1}$. We could also have defined \mathbb{P}^n to be the set of all lines through 0 in \mathbb{R}^{n+1} , since each such line intersects S^n in a set $\{p, -p\}$. More generally, we define the **Grassmannian manifold** $G_n(\mathbb{R}^N)$ to be the set of all n -dimensional subspaces of \mathbb{R}^N (we will always assume that $N > n$). In order to topologize $G_n(\mathbb{R}^N)$, we consider first the **Stiefel manifold** $V_n(\mathbb{R}^N)$ consisting of all n -tuples

$$(v_1, \dots, v_n) \in \mathbb{R}^N \times \dots \times \mathbb{R}^N$$

for which v_1, \dots, v_n are linearly independent. Clearly $V_n(\mathbb{R}^N)$ is an open subset of $\mathbb{R}^N \times \dots \times \mathbb{R}^N$. We can define a map

$$\rho: V_n(\mathbb{R}^N) \rightarrow G_n(\mathbb{R}^N)$$

by letting

$$\rho((v_1, \dots, v_n)) = \text{subspace of } \mathbb{R}^N \text{ spanned by } v_1, \dots, v_n.$$

We give $G_n(\mathbb{R}^N)$ the quotient topology for this map—thus $\mathcal{U} \subset G_n(\mathbb{R}^N)$ is open if and only if $\rho^{-1}(\mathcal{U}) \subset V_n(\mathbb{R}^N)$ is open.

We can also consider the subspace $V_n^O(\mathbb{R}^N) \subset V_n(\mathbb{R}^N)$ consisting of n -tuples $(v_1, \dots, v_n) \in V_n(\mathbb{R}^N)$ which are orthonormal. If $\rho_0 = \rho|_{V_n^O(\mathbb{R}^N)}$, then the diagram

$$\begin{array}{ccccc} V_n^O(\mathbb{R}^N) & \xrightarrow{i} & V_n(\mathbb{R}^N) & \xrightarrow{g} & V_n^O(\mathbb{R}^N) \\ & \searrow \rho_0 & \downarrow \rho & \swarrow \rho_0 & \\ & & G_n(\mathbb{R}^N) & & \end{array}$$

commutes, where i is the inclusion map, and $g((v_1, \dots, v_n))$ is the n -tuple in $V_n^O(\mathbb{R}^N)$ which results by applying the Gram-Schmidt orthonormalization process to v_1, \dots, v_n . From this diagram it is easy to see that the topology on $G_n(\mathbb{R}^N)$ can also be described as the quotient topology for ρ_0 . Since $V_n^O(\mathbb{R}^N)$ is compact, this shows that $G_n(\mathbb{R}^N)$ is also compact.

There is yet a third description of the topology of $G_n(\mathbb{R}^N)$ which will be important later on. Consider the orthogonal group $O(N)$. If $W_0 \subset \mathbb{R}^N$ is the n -dimensional subspace spanned by e_1, \dots, e_n , then we can define a map

$$O(N) \xrightarrow{\sigma} G_n(\mathbb{R}^N)$$

by

$$\sigma(A) = A(W_0) \in G_n(\mathbb{R}^N).$$

The following diagram then commutes,

$$\begin{array}{ccc} V_n^O(\mathbb{R}^N) & \xrightarrow{\rho} & G_n(\mathbb{R}^N) \\ \alpha \uparrow & \nearrow \sigma & \\ O(N) & & \end{array}$$

where α is the continuous map defined by

$$\alpha(A) = (A(e_1), \dots, A(e_n)) \in V_n^O(\mathbb{R}^N).$$

We thus see that if $\mathcal{U} \subset G_n(\mathbb{R}^N)$ is any set, then

$$\begin{aligned} (1) \quad \rho^{-1}(\mathcal{U}) \text{ is open} &\implies \alpha^{-1}(\rho^{-1}(\mathcal{U})) \text{ is open} \\ &\implies \sigma^{-1}(\mathcal{U}) \text{ is open.} \end{aligned}$$

Notice moreover that we clearly have

$$\alpha(\sigma^{-1}(\mathcal{U})) \subset \rho^{-1}(\mathcal{U}).$$

In addition, the map α is *onto* $V_n^O(\mathbb{R}^N)$, which easily implies that we actually have

$$\alpha(\sigma^{-1}(\mathcal{U})) = \rho^{-1}(\mathcal{U}).$$

Finally, the map α is an *open* map, so if $\mathcal{U} \subset G_n(\mathbb{R}^N)$, then

$$\begin{aligned} (2) \quad \sigma^{-1}(\mathcal{U}) \text{ is open} &\implies \alpha(\sigma^{-1}(\mathcal{U})) \text{ is open} \\ &\implies \rho^{-1}(\mathcal{U}) \text{ is open.} \end{aligned}$$

From (1) and (2) we see that the topology on $G_n(\mathbb{R}^N)$ can also be described as the quotient topology for σ .

This description of $G_n(\mathbb{R}^N)$ is useful for the following reason. The set

$$\sigma^{-1}(W_0) = \{A \in O(N) : A(W_0) = W_0\}$$

is easily seen to consist of all $N \times N$ matrices of the form

$$\begin{pmatrix} C & 0 \\ 0 & D \end{pmatrix} \quad \text{for } C \in O(n) \text{ and } D \in O(N-n).$$

For convenience, this group of matrices is usually denoted by $O(n) \times O(N - n)$. Now any other element of $G_n(\mathbb{R}^N)$ is of the form $B(W_0)$ for some $B \in O(N)$, and

$$\begin{aligned}\sigma^{-1}(B(W_0)) &= \{A \in O(N) : A(W_0) = B(W_0)\} \\ &= \{A \in O(N) : B^{-1}A(W_0) = W_0\} \\ &= \{A \in O(N) : B^{-1}A \in O(n) \times O(N - n)\} \\ &= \text{the left coset } B \cdot (O(n) \times O(N - n)).\end{aligned}$$

Thus we can identify $G_n(\mathbb{R}^N)$ with the left coset space

$$O(N)/O(n) \times O(N - n),$$

where this quotient space is given the quotient topology for the natural projection map

$$O(N) \longrightarrow O(N)/O(n) \times O(N - n).$$

In section 6 we will study in greater detail the quotient spaces G/H of a Lie group by a closed subgroup, and show that G/H is always a Hausdorff C^∞ manifold of dimension $\dim G - \dim H$. Thus $G_n(\mathbb{R}^N)$ will be a C^∞ manifold of dimension

$$\frac{N(N-1)}{2} - \left\{ \frac{n(n-1)}{2} + \frac{(N-n)(N-n-1)}{2} \right\} = n(N-n).$$

We can also describe this manifold structure on $G_n(\mathbb{R}^N)$ directly as follows. For any $W \in G_n(\mathbb{R}^N)$, consider the orthogonal complement $W^\perp \subset \mathbb{R}^N$. The decomposition $\mathbb{R}^N = W \oplus W^\perp$ determines an orthogonal projection

Let $\mathcal{U} \subset G_n(\mathbb{R}^N)$ be the set of all n -dimensional subspaces V with $V \cap W^\perp = \{0\}$, so that $p: V \rightarrow W$ is an isomorphism. Clearly $\rho^{-1}(\mathcal{U}) \subset V_n(\mathbb{R}^N)$ is open, so \mathcal{U} is an open subset of $G_n(\mathbb{R}^N)$. Now let w_1, \dots, w_n be a fixed orthonormal basis for W , and let w_{n+1}, \dots, w_N be a fixed orthonormal basis for W^\perp . For every $V \in \mathcal{U}$, there are unique $v_1, \dots, v_n \in V$ with $p(v_i) = w_i$, and these v_i can be written uniquely as

$$(*) \quad v_i = w_i + \sum_{j=n+1}^N a_{ij}(V) \cdot w_j.$$

The one-one map

$$V \mapsto (a_{ij}(V))$$

takes \mathcal{U} onto the set of $n \times (N - n)$ matrices. This map is continuous, since the v_i depend continuously on V ; moreover, the inverse map is

$$(a_{ij}) \mapsto \text{space spanned by the } w_i + \sum_{j=n+1}^N a_{ij} \cdot w_j,$$

which is also continuous. Thus we have mapped \mathcal{U} homeomorphically onto $\mathbb{R}^{n(N-n)}$. We leave it to the reader to check that any two such homeomorphisms are C^∞ -related. Thus $G_n(\mathbb{R}^N)$ is a C^∞ manifold. The reader may also check that the map

$$G_n(\mathbb{R}^{m+n}) \rightarrow G_m(\mathbb{R}^{m+n})$$

defined by taking an n -plane W to its orthogonal m -plane W^\perp is a diffeomorphism.

Over the Grassmannian manifold $G_n(\mathbb{R}^N)$ there is a natural n -dimensional bundle $\gamma^n(\mathbb{R}^N)$, constructed as follows. The total space $E(\gamma^n(\mathbb{R}^N))$ of the bundle will be the subset of $G_n(\mathbb{R}^N) \times \mathbb{R}^N$ consisting of all pairs

$$(W, w) \in G_n(\mathbb{R}^N) \times \mathbb{R}^N \quad \text{such that } w \in W,$$

and the projection map $\pi: E(\gamma^n(\mathbb{R}^N)) \rightarrow G_n(\mathbb{R}^N)$ will be $\pi((W, w)) = W$. Thus the fibre $\pi^{-1}(W)$ over the point W of $G_n(\mathbb{R}^N)$ will just be W itself—more precisely, it will be

$$\{(W, w) : w \in W\}.$$

The vector space structure on $\pi^{-1}(W)$ is defined by using the vector space structure on the subspace $W \subset \mathbb{R}^N$; thus

$$\begin{aligned} (W, w_1) + (W, w_2) &= (W, w_1 + w_2) \\ a \cdot (W, w) &= (W, aw). \end{aligned}$$

To show that $\gamma^n(\mathbb{R}^N)$ satisfies the local triviality condition, we consider a point $W \in G_n(\mathbb{R}^N)$, the orthogonal complement W^\perp , the corresponding projection $p: \mathbb{R}^N \rightarrow W$ and the open set $\mathcal{U} \subset G_n(\mathbb{R}^N)$ consisting of all V with $V \cap W^\perp = \{0\}$. Now we can define a map

$$\pi^{-1}(\mathcal{U}) \rightarrow \mathcal{U} \times W \approx \mathcal{U} \times \mathbb{R}^n$$

by taking

$$(V, v) \mapsto (V, p(v)).$$

This map is easily seen to be a diffeomorphism, and is an isomorphism on each fibre, so $\gamma^n(\mathbb{R}^N)$ is a smooth vector bundle over $G_n(\mathbb{R}^N)$.

Notice that for $M > N$ there is a natural map $\alpha: G_n(\mathbb{R}^N) \rightarrow G_n(\mathbb{R}^M)$, since an n -dimensional subspace of \mathbb{R}^N can be considered as an n -dimensional subspace of \mathbb{R}^M . There is also an obvious map $\tilde{\alpha}: E(\gamma^n(\mathbb{R}^N)) \rightarrow E(\gamma^n(\mathbb{R}^M))$ such that $(\tilde{\alpha}, \alpha)$ is a bundle map from $\gamma^n(\mathbb{R}^N)$ to $\gamma^n(\mathbb{R}^M)$. Thus

$$\gamma^n(\mathbb{R}^N) \simeq \alpha^*(\gamma^n(\mathbb{R}^M)).$$

Now consider a C^∞ manifold M^n immersed in \mathbb{R}^{n+1} . Since M need not be orientable, we may not be able to define the normal map $v: M^n \rightarrow S^n$. But we can certainly define a map $f: M \rightarrow \mathbb{P}^n = G_1(\mathbb{R}^{n+1})$, by taking $p \in M$ to the 1-dimensional subspace of \mathbb{R}^{n+1} which is parallel to the line $M_p^\perp \subset \mathbb{R}^{n+1}_p$.

We can also define a map \tilde{f} from the normal bundle $\text{Nor } M$ of M into the total space of $\gamma^1(\mathbb{R}^{n+1})$ by sending $v_p \in M_p^\perp$ to $(f(p), v)$. Thus we have a bundle map (\tilde{f}, f) from the normal bundle $\text{Nor } M$ to the bundle $\gamma^1(\mathbb{R}^{n+1})$; consequently, the normal bundle $\text{Nor } M$ is equivalent to $f^*(\gamma^1(\mathbb{R}^{n+1}))$. It is even more interesting to look at the map f from M into the diffeomorphic manifold $G_n(\mathbb{R}^{n+1})$ defined by $f(p) =$ subspace of \mathbb{R}^{n+1} parallel to M_p . For then we can define $\tilde{f}: TM \rightarrow E(\gamma^n(\mathbb{R}^{n+1}))$ by sending $v_p \in M_p$ to $(f(p), v)$. Thus we see that the tangent bundle TM is equivalent to $f^*(\gamma^n(\mathbb{R}^{n+1}))$. Moreover, this construction can be generalized. By Proposition I.2-17, any compact n -manifold M can be considered as a submanifold $M^n \subset \mathbb{R}^N$ for some N . Define $f: M \rightarrow G_n(\mathbb{R}^N)$ by $f(p) =$ subspace of \mathbb{R}^N parallel to M_p , and define $\tilde{f}: TM \rightarrow E(\gamma^n(\mathbb{R}^N))$ by sending $v_p \in M_p$ to $(f(p), v)$. Then (\tilde{f}, f) is a bundle map from TM to the bundle $\gamma^n(\mathbb{R}^N)$. Thus the tangent bundle TM is equivalent to $f^*(\gamma^n(\mathbb{R}^N))$. Actually, this holds for *all* bundles.

6. THEOREM. Let $\xi = \pi: E \rightarrow X$ be an n -dimensional bundle over a compact Hausdorff space X . Then for sufficiently large N there is a map $f: X \rightarrow G_n(\mathbb{R}^N)$ such that $\xi \simeq f^*(\gamma^n(\mathbb{R}^N))$.

If X is a smooth manifold and ξ is a smooth bundle, then f can be chosen to be a smooth map.

PROOF. Let U_1, \dots, U_r be open sets covering X such that each $\xi|_{U_i}$ is trivial. The Shrinking Lemma (Theorem I.2-14) holds for the cover U_1, \dots, U_r of X , for the proof merely uses the fact that X is normal. So there is an open cover V_1, \dots, V_r of X with $\bar{V}_i \subset U_i$. Similarly, there is an open cover W_1, \dots, W_r of X with $\bar{W}_i \subset V_i$. Let $\phi_i: X \rightarrow \mathbb{R}$ be a continuous function which is 1 on \bar{W}_i and 0 outside of V_i .

By assumption on the U_i , there are equivalences

$$t_i: \pi^{-1}(U_i) \rightarrow U_i \times \mathbb{R}^n.$$

Composing with the projections $U_i \times \mathbb{R}^n \rightarrow \mathbb{R}^n$, we thus obtain maps

$$\tau_i: \pi^{-1}(U_i) \rightarrow \mathbb{R}^n$$

which are isomorphism on each fibre. Define $\tau_i': E \rightarrow \mathbb{R}^n$ by

$$\tau_i'(e) = \begin{cases} 0 & \pi(e) \notin V_i \\ \phi_i(\pi(e)) \cdot \tau_i(e) & \pi(e) \in U_i. \end{cases}$$

These maps are linear on each fibre, but not one-one on all fibres. Now define

$$T: E \rightarrow \mathbb{R}^n \oplus \dots \oplus \mathbb{R}^n \approx \mathbb{R}^{rn}$$

by

$$T(e) = (\tau_1'(e), \dots, \tau_r'(e)).$$

Then T is linear and one-one on all fibres, so each set $T(\pi^{-1}(x))$ is an n -plane in \mathbb{R}^{rn} . Defining $f: X \rightarrow G_n(\mathbb{R}^{rn})$ and $\tilde{f}: E \rightarrow E(\gamma^n(\mathbb{R}^{rn}))$ by

$$\begin{aligned} f(x) &= T(\pi^{-1}(x)) = \{T(e) : e \in \pi^{-1}(x)\} \in G_n(\mathbb{R}^{rn}) \\ \tilde{f}(e) &= (f(\pi(e)), T(e)) \in E(\gamma^n(\mathbb{R}^{rn})), \end{aligned}$$

it is easily checked that (\tilde{f}, f) is a bundle map from ξ to $\gamma^n(\mathbb{R}^{rn})$.

When ξ is a smooth bundle, we choose the ϕ_i to be smooth, and then f will also be smooth. ♦

The map $f: X \rightarrow G_n(\mathbb{R}^N)$ of Theorem 6 cannot be unique, for Theorem 4 shows that $f^*(\gamma^n(\mathbb{R}^N)) \simeq g^*(\gamma^n(\mathbb{R}^N))$ whenever f and g are homotopic. But in a certain sense this is the only extent to which the representation fails to be unique:

7. THEOREM. Let $f_0, f_1: X \rightarrow G_n(\mathbb{R}^N)$ be two maps such that

$$f_0^* \gamma^n(\mathbb{R}^N) \simeq f_1^* \gamma^n(\mathbb{R}^N).$$

Consider the natural inclusion $\alpha: G_n(\mathbb{R}^N) \rightarrow G_n(\mathbb{R}^M)$, for $M \geq 2N$. Then $\tilde{f}_0 = \alpha \circ f_0$ and $\tilde{f}_1 = \alpha \circ f_1$ are homotopic.

If f_0 and f_1 are smooth maps, then \tilde{f}_0 and \tilde{f}_1 are smoothly homotopic.

PROOF. For each $x \in X$ we have two n -planes $f_0(x)$ and $f_1(x) \in G_n(\mathbb{R}^M)$. By assumption, there is a bundle map from the total space of $f_0^*(\gamma^n(\mathbb{R}^N))$ to the total space of $f_1^*(\gamma^n(\mathbb{R}^N))$. Recalling how these bundles are defined, we see that for each $x \in X$ we have an isomorphism

$$h(x): f_0(x) \rightarrow f_1(x),$$

depending continuously on x . First we consider a

Special Case. For all $x \in X$ and all non-zero $v \in f_0(x)$, the vector $h(x)(v)$ is never a negative multiple of v .

In this case, for each $t \in [0, 1]$ we define a map $h_t(x): f_0(x) \rightarrow \mathbb{R}^N$ by

$$h_t(x) = (1 - t) \cdot \text{identity} + t \cdot h(x).$$

For the image $h_t(x)(f_0(x)) \subset \mathbb{R}^N$ we have

$$h_0(x)(f_0(x)) = f_0(x)$$

$$h_1(x)(f_0(x)) = f_1(x).$$

We define a homotopy f_t between f_0 and f_1 by

$$f_t(x) = h_t(x)(f_0(x)).$$

The assumption in our special case insures that each $h_t(x)$ is one-one on $f_0(x)$, so that we have $f_t(x) \in G_n(\mathbb{R}^N)$. It is not hard to check that $(x, t) \mapsto f_t(x)$ is continuous on $X \times [0, 1]$, and is therefore the desired homotopy.

General Case. In the general case, the above construction does not work. Moreover, it may happen that the hypothesis for the special case will never occur even when we replace f_0 by some homotopic map f_0' . It is necessary to look at the compositions $\tilde{f}_0, \tilde{f}_1: X \rightarrow G_n(\mathbb{R}^M)$. Note that

$$\begin{aligned} \tilde{f}_i^* \gamma^n(\mathbb{R}^M) &= (\alpha \circ f_i)^* \gamma^n(\mathbb{R}^M) \\ &\simeq f_i^* \alpha^* \gamma^n(\mathbb{R}^M) \\ &\simeq f_i^* \gamma^n(\mathbb{R}^N). \end{aligned}$$

So by hypothesis we have

$$\bar{f}_0^* \gamma^n(\mathbb{R}^M) \simeq \bar{f}_1^* \gamma^n(\mathbb{R}^M).$$

Now since $M \geq 2N$, we can define a map $\mathbb{R}^M \rightarrow \mathbb{R}^M$ by

$$(a_1, \dots, a_N, a_{N+1}, \dots, a_{2N}, \dots) \mapsto (a_{N+1}, \dots, a_{2N}, a_1, \dots, a_N, \dots).$$

This induces a map $S: G_n(\mathbb{R}^M) \rightarrow G_n(\mathbb{R}^M)$, which is homotopic to the identity.

Thus $S \circ \bar{f}_1 \simeq \bar{f}_1$, so

$$\bar{f}_0^* \gamma^n(\mathbb{R}^M) \simeq \bar{f}_1^*(\gamma^n(\mathbb{R}^M)) \simeq (S \circ \bar{f}_1)^* \gamma^n(\mathbb{R}^M).$$

But \bar{f}_0 and $S \circ \bar{f}_1$ clearly satisfy the hypotheses of the special case. So we have

$$\bar{f}_0 \simeq S \circ \bar{f}_1 \simeq \bar{f}_1.$$

If f_0 and f_1 are smooth, so that \bar{f}_0 and \bar{f}_1 are smooth, then the homotopy constructed above is also smooth. ♦

In algebraic topology it is customary to consider the union $G_n(\mathbb{R}^\infty)$ of the increasing sequence

$$G_n(\mathbb{R}^{n+1}) \subset G_n(\mathbb{R}^{n+2}) \subset \dots$$

with the “weak topology”: a set $\mathcal{U} \subset G_n(\mathbb{R}^\infty) = \bigcup_l G_n(\mathbb{R}^{n+l})$ is open if and only if $\mathcal{U} \cap G_n(\mathbb{R}^{n+l})$ is open in $G_n(\mathbb{R}^{n+l})$ for all l . There is a natural n -dimensional bundle γ^n over $G_n(\mathbb{R}^\infty)$, defined analogously to $\gamma^n(\mathbb{R}^N)$, and this bundle has the following two properties:

- (A) For every bundle ξ over a paracompact space X there is a map $f: X \rightarrow G_n(\mathbb{R}^\infty)$ such that $\xi \simeq f^*(\gamma^n)$,
- (B) If $f_0, f_1: X \rightarrow G_n(\mathbb{R}^\infty)$ are maps of a paracompact space X into $G_n(\mathbb{R}^\infty)$ with $f_0^* \gamma^n \simeq f_1^* \gamma^n$, then $f_0 \simeq f_1$.

For this reason, γ^n is called the “universal n -dimensional bundle”, and $G_n(\mathbb{R}^\infty)$ is called the “classifying space” for n -dimensional bundles, since equivalence classes of n -dimensional bundles over X are classified by homotopy classes of maps of X into $G_n(\mathbb{R}^\infty)$. Since $G_n(\mathbb{R}^\infty)$ is not a manifold, we do not work with these bundles. Instead we will continue to use the bundles $\gamma^n(\mathbb{R}^N)$, which we also call, somewhat sloppily, “universal bundles”.

All of the preceding discussion can be modified to deal with oriented bundles. Recall that an **orientation** μ for a vector space V is an equivalence class of

ordered bases for V , where $(v_1, \dots, v_n) \sim (w_1, \dots, w_n)$ if and only if the matrix (a_{ij}) defined by $w_i = \sum_j a_{ji} v_j$ has $\det(a_{ij}) > 0$. There are only two such equivalence classes, and the one which is not μ is denoted by $-\mu$. An **oriented** vector space is a pair (V, μ) , where μ is an orientation for V ; the condition $(v_1, \dots, v_n) \in \mu$ is usually expressed by saying that v_1, \dots, v_n is positively oriented (with respect to μ). Given two oriented vector spaces (V, μ) and (W, ν) , we orient $V \oplus W$ by declaring $v_1, \dots, v_n, w_1, \dots, w_m$ to be positively oriented if v_1, \dots, v_n and w_1, \dots, w_m are positively oriented with respect to μ and ν , respectively. Thus the orientation for $W \oplus V$ is $(-1)^{mn}$ times the orientation for $V \oplus W$.

An **orientation** for a bundle $\xi = \pi: E \rightarrow X$ is a collection $\mu = \{\mu_x\}$ of orientations for the fibres $\pi^{-1}(x)$, satisfying an obvious compatibility requirement, while an **oriented bundle** is a pair (ξ, μ) , where μ is an orientation for ξ . An orientation μ for ξ gives us another orientation $-\mu = \{-\mu_x\}$; if X is connected, this is the only other orientation for ξ . Given two oriented bundles (ξ_1, μ_1) and (ξ_2, μ_2) over the same space X , we can define an orientation on the Whitney sum $\xi_1 \oplus \xi_2$ by using the orientation on the direct sums of fibres described in the previous paragraph; thus we can define $(\xi_1 \oplus \xi_2, \mu_1 \oplus \mu_2)$ to be $\xi_1 \oplus \xi_2$ with this orientation. Given an oriented bundle (ξ, μ) over Y , and a continuous map $f: X \rightarrow Y$, there is an obvious way to define an orientation $f^*\mu$ for $f^*\xi$; thus we can define $f^*(\xi, \mu)$ to be the oriented bundle $(f^*\xi, f^*\mu)$.

For two bundles ξ_1, ξ_2 with orientations μ_1, μ_2 , respectively, we can speak of orientation preserving bundle maps and equivalences, or we can simply speak of bundle maps and equivalences between the oriented bundles (ξ_1, μ_1) and (ξ_2, μ_2) . Notice that the oriented bundles (ξ, μ) and $(\xi, -\mu)$ need not be equivalent. For example, if μ is an orientation of the tangent bundle of S^2 , then (TS^2, μ) and $(TS^2, -\mu)$ are not equivalent. In fact, an orientation preserving equivalence from (TS^2, μ) to $(TS^2, -\mu)$ would give us a continuous family of isomorphisms

$$A_p: S^2_p \rightarrow S^2_p, \quad \text{with all } \det A_p < 0.$$

Now a linear transformation $A: V \rightarrow V$ from a 2-dimensional vector space V to itself has two complex eigenvalues λ_1, λ_2 , and if λ_1 is not real, then $\lambda_2 = \overline{\lambda_1}$. But the condition $\det A = \lambda_1 \lambda_2 < 0$ clearly implies that we do not have $\lambda_2 = \overline{\lambda_1}$, so A has two real eigenvalues of opposite signs. Thus we could use the A_p to continuously pick out a 1-dimensional subspace of S^2_p for all $p \in S^2$, by choosing the eigenvectors with the positive eigenvalue for A_p . But such a continuous choice cannot be made, by Problem I.9-7.

We define the **oriented Grassmannian manifold** $\tilde{G}_n(\mathbb{R}^N)$ to be the set of all oriented n -dimensional subspaces of \mathbb{R}^N . We have already defined the map

$\rho: V_n(\mathbb{R}^N) \rightarrow G_n(\mathbb{R}^N)$, where $V_n(\mathbb{R}^N)$ is the Stiefel manifold. We can define a map

$$\tilde{\rho}: V_n(\mathbb{R}^N) \rightarrow \tilde{G}_n(\mathbb{R}^N)$$

by setting

$$\tilde{\rho}((v_1, \dots, v_n)) = (\rho(v_1, \dots, v_n), \mu),$$

where μ is the orientation of $\rho(v_1, \dots, v_n)$ determined by the ordered basis v_1, \dots, v_n . We give $\tilde{G}_n(\mathbb{R}^N)$ the quotient topology for $\tilde{\rho}$. If $\tilde{\rho}_0 = \tilde{\rho}|_{V_n^O(\mathbb{R}^N)}$, then the diagram

$$\begin{array}{ccccc} V_n^O(\mathbb{R}^N) & \xrightarrow{i} & V_n(\mathbb{R}^N) & \xrightarrow{g} & V_n^O(\mathbb{R}^N) \\ & \searrow \tilde{\rho}_0 & \downarrow \tilde{\rho} & \swarrow \tilde{\rho}_0 & \\ & & \tilde{G}_n(\mathbb{R}^N) & & \end{array}$$

commutes; to prove this, one just has to check that the Gram-Schmidt process g preserves orientation. So the topology on $\tilde{G}_n(\mathbb{R}^N)$ could also be described as the quotient topology for $\tilde{\rho}_0$.

Similarly, we can define a map on the special orthogonal group,

$$\tilde{\sigma}: \text{SO}(M) \rightarrow \tilde{G}_n(\mathbb{R}^N),$$

by

$$\tilde{\sigma}(A) = (A(W_0), \mu),$$

where the orientation μ on $A(W_0)$ is that determined by the ordered basis $A(e_1), \dots, A(e_n)$. The diagram

$$\begin{array}{ccc} V_n^O(\mathbb{R}^N) & \xrightarrow{\tilde{\rho}} & \tilde{G}_n(\mathbb{R}^N) \\ \alpha|_{\text{SO}(N)} \uparrow & \nearrow \tilde{\sigma} & \\ \text{SO}(N) & & \end{array}$$

commutes, and $\alpha|_{\text{SO}(N)}$ is onto for $N > n$. So, as before, we see that the topology on $\tilde{G}_n(\mathbb{R}^N)$ can be described as the quotient topology for $\tilde{\sigma}$. It is then easy to see that $\tilde{G}_n(\mathbb{R}^N)$ can be identified with the left coset space

$$\text{SO}(\bar{N}) / \text{SO}(n) \times \text{SO}(N - n).$$

There is a natural map $\tau: \tilde{G}_n(\mathbb{R}^N) \rightarrow G_n(\mathbb{R}^N)$ defined by

$$\tau((W, \mu)) = W.$$

If $W \in G_n(\mathbb{R}^N)$ and $\mathcal{U} \subset G_n(\mathbb{R}^N)$ is the open set on page 275, with w_1, \dots, w_n a fixed orthonormal basis for W , then every $V \in \mathcal{U}$ can be given the orientation $\mu(V)$ determined by the ordered basis v_1, \dots, v_n , where v_i are the unique vectors in V with $p(v_i) = w_i$. The sets

$$\begin{aligned}\mathcal{U}^+ &= \{(V, \mu(V)) : V \in \mathcal{U}\} \\ \mathcal{U}^- &= \{(V, -\mu(V)) : V \in \mathcal{U}\}\end{aligned}$$

are easily seen to be disjoint open subsets of $\tilde{G}_n(\mathbb{R}^N)$. Thus we see that $\tilde{G}_n(\mathbb{R}^N)$ is a smooth manifold, and that $\tau: \tilde{G}_n(\mathbb{R}^N) \rightarrow G_n(\mathbb{R}^N)$ is a 2-fold covering. As a matter of fact, $\tilde{G}_n(\mathbb{R}^N)$ is clearly the oriented 2-fold covering of the non-orientable manifold $G_n(\mathbb{R}^N)$, as described in Problem 8-2.

Over $\tilde{G}_n(\mathbb{R}^N)$ we define an oriented n -dimensional bundle $(\tilde{\gamma}^n(\mathbb{R}^N), \mu)$ as follows. The total space $E(\tilde{\gamma}^n(\mathbb{R}^N))$ consists of all pairs

$$((W, \mu), w) \in \tilde{G}_n(\mathbb{R}^N) \times \mathbb{R}^N \quad \text{such that } w \in W,$$

and we define $\pi((W, \mu), w) = W$. The vector space structure on $\pi^{-1}((W, \mu))$ is defined as before, and we can also define the natural orientation μ on

$$\pi^{-1}((W, \mu)) = \{((W, \mu), w) : w \in W\}$$

by using the orientation μ on W . (We ought to use a symbol like $\mu_{n,N}$, but for simplicity we won't.) Note that $\tau^*\gamma^n(\mathbb{R}^N)$ is equivalent to the bundle $\tilde{\gamma}^n(\mathbb{R}^N)$, where we forget about the orientation μ . For $M > N$ there is a natural map $\alpha: \tilde{G}_n(\mathbb{R}^N) \rightarrow \tilde{G}_n(\mathbb{R}^M)$, with

$$(\tilde{\gamma}^n(\mathbb{R}^N), \mu) \simeq \alpha^*(\tilde{\gamma}^n(\mathbb{R}^M), \mu).$$

8. THEOREM. (1) Let (ξ, μ) be an oriented n -dimensional bundle over a compact Hausdorff space X . Then for sufficiently large N there is a map $f: X \rightarrow \tilde{G}_n(\mathbb{R}^N)$ such that $(\xi, \mu) \simeq f^*(\tilde{\gamma}^n(\mathbb{R}^N), \mu)$. If X is a smooth manifold and ξ is a smooth bundle, then f can be chosen to be a smooth map.

(2) Let $f_0, f_1: X \rightarrow \tilde{G}_n(\mathbb{R}^N)$ be two maps such that $f_0^*(\tilde{\gamma}^n(\mathbb{R}^N), \mu) \simeq f_1^*(\tilde{\gamma}^n(\mathbb{R}^N), \mu)$. Then the compositions $\tilde{f}_0 = \alpha \circ f_0$ and $\tilde{f}_1 = \alpha \circ f_1$ are homotopic, where $\alpha: \tilde{G}_n(\mathbb{R}^N) \rightarrow \tilde{G}_n(\mathbb{R}^M)$ is the natural inclusion, and $M \geq 2N$. If f_0 and f_1 are smooth maps, then \tilde{f}_0 and \tilde{f}_1 are smoothly homotopic.

PROOF. Left to the reader. ♦

3. THE PFAFFIAN

We have already given an intrinsic expression, as well as an expression in terms of a coordinate system, for the function K_n on a compact oriented Riemannian manifold M of even dimension $n = 2m$. But the most important expression for K_n involves the curvature forms Ω_j^i for a positively oriented orthonormal moving frame X_1, \dots, X_n on M . In terms of these forms, we can easily write down the n -form $K_n dV$ which we want to integrate over M . We will be using the symbol $\varepsilon^{j_1 \dots j_n}$ (defined on pg. IV.68); notice that a sum over permutations, like

$$\sum_{\pi \in S_n} A(X_{\pi(1)}, \dots, X_{\pi(n)}),$$

for example, can just as well be written as

$$\sum_{j_1, \dots, j_n} \varepsilon^{j_1 \dots j_n} A(X_{j_1}, \dots, X_{j_n}).$$

Now consider the m -fold wedge product

$$\Omega_{i_2}^{i_1} \wedge \dots \wedge \Omega_{i_n}^{i_{n-1}}.$$

From the definition of \wedge we have (remembering that the Ω_j^i are 2-forms)

$$\begin{aligned} & \Omega_{i_2}^{i_1} \wedge \dots \wedge \Omega_{i_n}^{i_{n-1}}(X_1, \dots, X_n) \\ &= \frac{(2 + \dots + 2)!}{2! \dots 2!} \cdot \frac{1}{n!} \sum_{j_1, \dots, j_n} \varepsilon^{j_1 \dots j_n} \Omega_{i_2}^{i_1}(X_{j_1}, X_{j_2}) \dots \Omega_{i_n}^{i_{n-1}}(X_{j_{n-1}}, X_{j_n}) \\ &= \frac{1}{2^{n/2}} \cdot \sum_{j_1, \dots, j_n} \varepsilon^{j_1 \dots j_n} \langle R(X_{j_1}, X_{j_2})X_{i_2}, X_{i_1} \rangle \dots \langle R(X_{j_{n-1}}, X_{j_n})X_{i_n}, X_{i_{n-1}} \rangle \\ &= \frac{1}{2^{n/2}} \cdot \sum_{j_1, \dots, j_n} \varepsilon^{j_1 \dots j_n} R_{i_1 i_2 j_1 j_2} \dots R_{i_{n-1} i_n j_{n-1} j_n} \quad (\text{see pg. II.190}). \end{aligned}$$

So the formula on page 264 gives

$$K_n = \frac{1}{2^{n/2} n!} \sum_{i_1, \dots, i_n} \varepsilon^{i_1 \dots i_n} \cdot 2^{n/2} \cdot \Omega_{i_2}^{i_1} \wedge \dots \wedge \Omega_{i_n}^{i_{n-1}}(X_1, \dots, X_n),$$

and thus

$$K_n dV = \frac{1}{n!} \sum_{i_1, \dots, i_n} \varepsilon^{i_1 \dots i_n} \Omega_{i_2}^{i_1} \wedge \dots \wedge \Omega_{i_n}^{i_{n-1}}.$$

This computation shows, in particular, that the form on the right does not depend on the choice of the positively oriented orthonormal moving frame X_1, \dots, X_n . It is also possible to prove this fact directly, by the following algebraic considerations.

For an $n \times n$ matrix $A = (a_{ij})$ with $n = 2m$ even, we define the **Pfaffian** $\text{Pf}(A)$ of A by

$$\text{Pf}(A) = \frac{1}{2^m m!} \sum_{i_1, \dots, i_n} \varepsilon^{i_1 \dots i_n} a_{i_1 i_2} \cdots a_{i_{n-1} i_n}.$$

It will soon become clear why the factor $1/2^m m!$ should appear. At the moment we can account for the $1/m!$ by observing that our expression has a lot of redundancy in it. Note first that $\varepsilon^{i_1 \dots i_n}$ does not change when we interchange i_{2l-1} and i_{2l} and also i_{2l-1} and i_{2k} ; more generally, it does not change when we perform any permutation of the *pairs* (i_{2l-1}, i_{2l}) . So for any set $P = \{(h_1, k_1), \dots, (h_m, k_m)\}$ of pairs of integers between 1 and n , it makes sense to define

$$\varepsilon(P) = \varepsilon^{h_1 k_1 \dots h_m k_m};$$

it is not necessary to specify any ordering on the pairs (h_i, k_i) in P . Notice also that a permutation of the pairs (i_{2l-1}, i_{2l}) does not change the factor

$$a_{i_1 i_2} \cdots a_{i_{n-1} i_n}.$$

So for each P as above we can define

$$a_P = a_{h_1 k_1} \cdots a_{h_m k_m}.$$

If \mathcal{P} is the collection of all such P , we then clearly have

$$\text{Pf}(A) = \frac{1}{2^m} \sum_{P \in \mathcal{P}} \varepsilon(P) a_P.$$

9. PROPOSITION. Let $n = 2m$ be even. Then for all $n \times n$ matrices A and B we have

$$\text{Pf}(B^t A B) = (\det B) \cdot \text{Pf}(A),$$

where t denotes the transpose. In particular, if $B \in \text{SO}(n)$, then

$$\text{Pf}(B^{-1} A B) = \text{Pf}(A).$$

PROOF. We have

$$\begin{aligned}
 2^m m! \operatorname{Pf}(B^t A B) &= \sum_{i_1, \dots, i_n} \varepsilon^{i_1 \dots i_n} \sum_{j_1, \dots, j_n} (b_{j_1 i_1} a_{j_1 j_2} b_{j_2 i_2}) \cdots (b_{j_{n-1} i_{n-1}} a_{j_{n-1} j_n} b_{j_n i_n}) \\
 &= \sum_{j_1, \dots, j_n} \left[\sum_{i_1, \dots, i_n} \varepsilon^{i_1 \dots i_n} b_{j_1 i_1} \cdots b_{j_n i_n} \right] \cdot a_{j_1 j_2} \cdots a_{j_{n-1} j_n} \\
 &= \sum_{j_1, \dots, j_n} (\varepsilon^{j_1 \dots j_n} \det B) \cdot a_{j_1 j_2} \cdots a_{j_{n-1} j_n} \\
 &= 2^m m! (\det B) \operatorname{Pf}(A). \quad \blacklozenge
 \end{aligned}$$

Proposition 9 was stated for matrices of real numbers, but $\operatorname{Pf}(A)$ can be defined so long as the entries of A are in some commutative algebra \mathcal{A} over \mathbb{R} . It is easy to see that Proposition 9 still holds when A and B have entries in \mathcal{A} ; in fact, the proof works without change. We could also deduce this extended version from the original Proposition by the “principle of extension of algebraic identities”: First consider the ring $\mathbb{R}[A_{ij}, B_{ij}]$ obtained by adjoining commuting indeterminates A_{ij} and B_{ij} to \mathbb{R} . Then the polynomials

$$\operatorname{Pf}(B^t A B) \quad \text{and} \quad (\det B) \cdot \operatorname{Pf}(A)$$

are elements of $\mathbb{R}[A_{ij}, B_{ij}]$. Proposition 9 tells us that these polynomials have the same values on all $(a_{ij}), (b_{ij})$ for $a_{ij}, b_{ij} \in \mathbb{R}$. Therefore they are equal *as polynomials* in the indeterminates A_{ij}, B_{ij} . So these polynomials are equal when we substitute elements a_{ij}, b_{ij} of the algebra \mathcal{A} for the indeterminates A_{ij}, B_{ij} . Q.E.D.

Now let us consider once again a positively oriented orthonormal moving frame $\mathbf{X} = X_1, \dots, X_n$ on M , with curvature forms Ω_j^i . For each $p \in M$, the direct sum

$$\mathcal{A} = \mathbb{R} \oplus \Omega^2(M_p) \oplus \Omega^4(M_p) \oplus \cdots$$

is a commutative algebra over \mathbb{R} , under \wedge . Consequently, it makes sense to write $\operatorname{Pf}(\Omega(p))$, where $\Omega(p)$ is the $n \times n$ matrix $(\Omega_j^i(p))$ of connection 2-forms at p . In fact, we clearly have

$$\operatorname{Pf}(\Omega(p)) = \frac{1}{2^m m!} \sum_{i_1, \dots, i_n} \varepsilon^{i_1 \dots i_n} \Omega_{i_2}^{i_1} \wedge \cdots \wedge \Omega_{i_n}^{i_{n-1}}(p).$$

Now if $\mathbf{X}' = \mathbf{X} \cdot a$ is another positively oriented orthonormal moving frame, then $a(p) \in O(n)$, and by Proposition II.7-15 the corresponding curvature forms (Ω'^i_j) satisfy

$$\Omega' = a^{-1} \Omega a.$$

Then Proposition 9, in its extended form, shows that

$$\text{Pf}(\Omega'(p)) = \text{Pf}(a^{-1}(p)\Omega(p)a(p)) = \text{Pf}(\Omega(p));$$

thus the form

$$\sum_{i_1, \dots, i_n} \varepsilon^{i_1 \dots i_n} \Omega_{i_2}^{i_1} \wedge \dots \wedge \Omega_{i_n}^{i_{n-1}}$$

is indeed well-defined.

Later on we will need to know the important algebraic properties of $\text{Pf}(A)$ that hold when A is *skew-symmetric*. In this case, even the expression

$$\text{Pf}(A) = \frac{1}{2^m} \sum_{P \in \mathcal{P}} \varepsilon(P) a_P$$

is redundant, for the term

$$\varepsilon^{i_1 \dots i_n} a_{i_1 i_2} \dots a_{i_{n-1} i_n}$$

is unchanged when we interchange i_{2l-1} and i_{2l} . Let $\mathcal{P}' \subset \mathcal{P}$ be the collection of all $P = \{(h_1, k_1), \dots, (h_m, k_m)\} \in \mathcal{P}$ with $h_i < k_i$ for all i . Then for skew-symmetric A we clearly have

$$\text{Pf}(A) = \sum_{P \in \mathcal{P}'} \varepsilon(P) a_P,$$

which is a polynomial with integer coefficients. (It follows that $\text{Pf}(A)$ can be defined for a skew-symmetric matrix A with entries in any commutative ring \mathcal{A} with unit.)

There is an important canonical form for skew-symmetric matrices, which is merely a reformulation of the following result which has already appeared in Problem I.7-8.

10. PROPOSITION. Let V be an n -dimensional vector space, and let $\alpha \in \Omega^2(V)$. Then there is a basis ϕ_1, \dots, ϕ_n of V^* such that

$$\alpha = (\phi_1 \wedge \phi_2) + \dots + (\phi_{2r-1} \wedge \phi_{2r})$$

for some r . (For $\alpha = 0$ we must allow the vacuous sum, with $r = 0$.) If $\{\phi_i\}$ is the dual basis to $\{v_i\}$, this means that

$$(1) \quad \begin{cases} \alpha(v_{2i-1}, v_{2i}) = -\alpha(v_{2i}, v_{2i-1}) = 1 & \text{for } i \leq r \\ \alpha(v_i, v_j) = 0 & \text{for all other pairs } i, j. \end{cases}$$

PROOF. We use induction on n , the result being trivial for $n = 1$. Assume the result is true for dimensions $< n$, and consider a non-zero $\alpha \in \Omega^2(V)$, where V has dimension n . There exist $v_1, v_2 \in V$ with $\alpha(v_1, v_2) = 1$; let $[v_1, v_2]$ be the subspace generated by v_1 and v_2 . Now consider the subspace $W \subset V$ of all $v \in V$ such that $\alpha(v_1, v) = \alpha(v_2, v) = 0$. This subspace W is $\ker f_1 \cap \ker f_2$ where $f_i: V \rightarrow \mathbb{R}$ is defined by $f_i(v) = \alpha(v_i, v)$. So $\dim W \geq n - 2$. Moreover, we clearly have $W \cap [v_1, v_2] = \{0\}$, so $\dim W = n - 2$ and $V = [v_1, v_2] \oplus W$. Since the result is assumed true for $\alpha|_{W \times W}$, there is a basis v_3, \dots, v_n of W such that (I) holds for these v_i . Then $v_1, v_2, v_3, \dots, v_n$ is the desired basis. ♦

11. COROLLARY. Let $A = (a_{ij})$ be an $n \times n$ skew-symmetric matrix. Then there is a non-singular $n \times n$ matrix B such that

$$B^t A B = \begin{pmatrix} S & & & & \\ & S & & & \\ & & \ddots & & \\ & & & S & \\ & & & & 0 \\ & & & & 0 & \ddots \\ & & & & & & 0 \end{pmatrix},$$

where S is the matrix

$$S = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

PROOF. Let e_1, \dots, e_n be the standard basis of \mathbb{R}^n , and define $\alpha \in \Omega^2(\mathbb{R}^n)$ by

$$\alpha(e_i, e_j) = a_{ij}.$$

Let v_1, \dots, v_n be the basis of \mathbb{R}^n given by Proposition 10, and let $B = (b_{ij})$ be the matrix defined by

$$v_i = \sum_{k=1}^n b_{ki} e_k.$$

Then

$$\begin{aligned} \alpha(v_i, v_j) &= \alpha\left(\sum_k b_{ki} e_k, \sum_l b_{lj} e_l\right) \\ &= \sum_{k,l} b_{ki} b_{lj} \alpha(e_k, e_l) \\ &= \sum_{k,l} b_{ki} b_{lj} a_{kl} = (B^t A B)_{ij}, \end{aligned}$$

which gives the desired result. ♦

Using the expression

$$\text{Pf}(A) = \sum_{P \in \mathcal{P}'} \varepsilon(P) a_P$$

for skew-symmetric A , it is easy to compute that

$$\text{Pf} \begin{pmatrix} S & & 0 \\ & \ddots & \\ 0 & & S \end{pmatrix} = 1.$$

On the other hand, this matrix also has determinant = 1. This gives us

12. COROLLARY. For every skew-symmetric $n \times n$ matrix A with $n = 2m$ even we have

$$\{\text{Pf}(A)\}^2 = \det A.$$

PROOF. It suffices to prove this when $\det A \neq 0$, since both sides are continuous functions of the entries of A and the matrices with non-zero determinant are dense. By Corollary 11, there is a non-singular $n \times n$ matrix B with

$$B^t A B = \begin{pmatrix} S & & 0 \\ & \ddots & \\ 0 & & S \end{pmatrix}.$$

Then

$$1 = \det \begin{pmatrix} S & & 0 \\ & \ddots & \\ 0 & & S \end{pmatrix} = (\det B)^2 \cdot \det A,$$

while Proposition 9 gives

$$1 = \text{Pf} \begin{pmatrix} S & & 0 \\ & \ddots & \\ 0 & & S \end{pmatrix} = (\det B) \text{Pf}(A). \quad \blacklozenge$$

For a skew-symmetric $n \times n$ matrix A with n odd we define

$$\text{Pf}(A) = 0.$$

Note that in this case we have

$$\det A = \det A^t = \det(-A) = (-1)^n \det A \implies \det A = 0.$$

So Corollary 12 still holds.

For even n the skew-symmetry of A is likewise crucial in Corollary 12. If we consider $\det(A_{ij})$ as a polynomial in n^2 independent commuting variables A_{ij} , then $\det(A_{ij})$ is *not* the square of another polynomial. But if we consider $\det(A_{ij})$ as a polynomial in the $n(n-1)/2$ independent commuting variables A_{ij} for $i < j$ [and define $A_{ii} = 0$, $A_{ij} = -A_{ji}$ for $i > j$], then $\det(A_{ij}) = \{\text{Pf}(A)\}^2$ as polynomials in these A_{ij} , since the two polynomials give the same results when applied to all real numbers a_{ij} , $i < j$. Since $\mathbb{R}[A_{ij}]$ is a unique factorization domain, $\text{Pf}(A)$ and $-\text{Pf}(A)$ are the only two polynomials with this property. The principal of extension of algebraic identities shows that $\det A = \{\text{Pf}(A)\}^2$ when A is a $2m \times 2m$ skew-symmetric matrix with entries in any commutative ring \mathcal{A} with unit.

[By working in the ring $\mathbb{R}[A_{ij}]$, we could have produced the Pfaffian in a neat, mysterious, way that avoids all computations. For there is a matrix X with entries in the quotient field of $\mathbb{R}[A_{ij}]$ such that

$$X^t A X = \begin{pmatrix} S & & 0 \\ & \ddots & \\ 0 & & S \end{pmatrix}.$$

Hence the polynomial $\det A$ in $\mathbb{R}[A_{ij}]$ is the square $(\det X)^{-2}$ in the quotient field of $\mathbb{R}[A_{ij}]$. Since $\mathbb{R}[A_{ij}]$ is a unique factorization domain, this implies that $\det A$ is already a square in $\mathbb{R}[A_{ij}]$. There are only two possible elements $\text{Pf}(A)$ for $\det A$ to be the square of, and we determine $\text{Pf}(A)$ by requiring that Pf have the value $+1$ on

$$\begin{pmatrix} S & & 0 \\ & \ddots & \\ 0 & & S \end{pmatrix}.$$

Similarly, if we consider the ring $\mathbb{R}[A_{ij}, B_{11}, \dots, B_{nn}]$ in the indeterminants A_{ij} for $i < j$, and B_{ij} for all i, j , then the identity $\det B^t A B = (\det B)^2 \det A$ implies that

$$\text{Pf}(B^t A B) = \pm(\det B) \text{Pf} A,$$

and by choosing $B = I$ we see that the sign must be $+1$.]

As a rather trivial example of the use of polynomial rings to avoid some computations, we prove one more simple, but important property of Pf . If A and B are two square matrices, we will use $A \oplus B$ for the matrix

$$\begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix}.$$

13. COROLLARY. For all skew-symmetric matrices A and B we have

$$\text{Pf}(A \oplus B) = \text{Pf}(A) \cdot \text{Pf}(B).$$

Note: This result holds even when A or B , or both, is of odd order. In that case it says that $\text{Pf}(A \oplus B) = 0$.

PROOF. By Corollary 12 (which holds even for matrices of odd order) we have

$$(1) \quad \{\text{Pf}(A \oplus B)\}^2 = \det(A \oplus B) = \det A \cdot \det B = \{\text{Pf}(A) \text{Pf}(B)\}^2,$$

and thus

$$(2) \quad \text{Pf}(A \oplus B) = \pm \text{Pf}(A) \text{Pf}(B).$$

If A or B is of odd order, then we already have $\text{Pf}(A \oplus B) = 0$. For A and B of even order, we just need to determine the sign in (2). Now the same sign must hold in (2) for all A and B , for we may consider equation (1) as an equation in the ring $\mathbb{R}[A_{ij}, B_{ij}]$ with commuting variables A_{ij}, B_{ij} ($i < j$ in both cases). Letting A and B be of the form $S \oplus \cdots \oplus S$, we see that the $+$ sign always holds. ♦

4. DEFINING THE EULER CLASS IN TERMS OF A CONNECTION

Consider a smooth oriented n -dimensional vector bundle $\xi = \pi: E \rightarrow M$, over a smooth manifold M (of any dimension). For compact orientable M we defined the Euler class $\chi(\xi) \in H^n(M)$ in Chapter I.11. To do this, we first defined the Thom class $U(\xi) \in H_c^n(E)$, and we proved (Theorem I.11-26) that $U(\xi)$ is the unique class whose restriction to each fibre $\pi^{-1}(p)$ is the generator $\nu_p \in H_c^n(\pi^{-1}(p))$ determined by the orientation. From this result we can immediately conclude

14. LEMMA. Let $\xi = \pi: E \rightarrow M$ be a smooth oriented vector bundle over a compact oriented manifold M , and let $f: M' \rightarrow M$ be a smooth map, where M' is also a compact oriented manifold. If E' is the total space of $f^*\xi$, and $\tilde{f}: E' \rightarrow E$ is a bundle map covering f , then

$$\tilde{f}^*(U(\xi)) = U(f^*\xi) \in H_c^n(E').$$

PROOF. Note first that \tilde{f} is proper (the inverse image of a compact set is compact), so \tilde{f}^* does take $H_c^n(E)$ to $H_c^n(E')$. Let $f^*\xi$ be $\pi': E' \rightarrow M'$. If $p' \in M'$ is any point, and $j_{p'}: \pi'^{-1}(p') \rightarrow E'$ is the inclusion, then

$$j_{p'}^* \tilde{f}^* U(\xi) = (\tilde{f} \circ j_{p'})^* U(\xi).$$

If we recall how $f^*\xi$ is defined, we see that $(\tilde{f} \circ j_{p'})^* U(\xi)$ must be the generator of $H_c^n(\pi'^{-1}(p'))$, since $j_{f(p')}^* U(\xi)$ is the generator of $H_c^n(\pi^{-1}(f(p')))$. This shows that $\tilde{f}^* U(\xi)$ must be $U(f^*\xi)$. ♦

We defined the Euler class $\chi(\xi)$ to be $s^* U(\xi)$, for any section s of ξ . In particular, we can choose $s = 0 =$ the zero section. Hence

15. PROPOSITION. Let $\xi = \pi: E \rightarrow M$ be a smooth oriented vector bundle over a compact oriented manifold M , and let $f: M' \rightarrow M$ be a smooth map, where M' is also a compact oriented manifold. Then

$$f^* \chi(\xi) = \chi(f^* \xi) \in H^n(M').$$

PROOF. If $0'$ denotes the zero section of $f^* \xi$, then $\tilde{f} \circ 0' = 0 \circ f$. So

$$\begin{aligned} \chi(f^* \xi) &= (0')^* U(f^* \xi) \\ &= (0')^* \tilde{f}^* U(\xi) \quad \text{by Lemma 14} \\ &= (\tilde{f} \circ 0')^* U(\xi) = (0 \circ f)^* U(\xi) \\ &= f^* 0^* U(\xi) = f^* \chi(\xi). \quad \spadesuit \end{aligned}$$

As a particular consequence, we note a result which we will need later on.

16. COROLLARY. If n is even, then

$$\chi(\tilde{\gamma}^n(\mathbb{R}^N)) \neq 0$$

for all $N > n$.

PROOF. Since $S^n \subset \mathbb{R}^N$ for $N > n$, we have a bundle map $(\tilde{f}, f): TS^n \rightarrow E(\tilde{\gamma}^n(\mathbb{R}^N))$, as on page 277. So

$$\chi(TS^n) = f^* \chi(\tilde{\gamma}^n(\mathbb{R}^N)).$$

But Theorem I.11-30 says that $\chi(TS^n)$ is $\chi(S^n)$ times the fundamental class of S^n , and $\chi(S^n) = 2 \neq 0$. ♦

The Euler class has one further important property which it is not really essential to prove at this point, for it could eventually be derived from other results of this section. Nevertheless, it will motivate much of the argument to come.

17. THEOREM. Let $\xi_i = \pi_i: E_i \rightarrow M$ for $i = 1, 2$ be smooth oriented vector bundles over a compact oriented manifold M . Then $\chi(\xi_1 \oplus \xi_2)$ is the cup product.

$$\chi(\xi_1 \oplus \xi_2) = \chi(\xi_1) \cup \chi(\xi_2).$$

PROOF. The Whitney sum $\xi_1 \oplus \xi_2$ is $\pi: E \rightarrow M$ where $E \subset E_1 \times E_2$ is $\{(e_1, e_2) : \pi_1(e_1) = \pi_2(e_2)\}$. Let $\rho_i: E \rightarrow E_i$ be the restriction of the projection maps $E_1 \times E_2 \rightarrow E_i$. For any $p \in M$, let

$$j: \pi^{-1}(p) \rightarrow E, \quad j_i: \pi_i^{-1}(p) \rightarrow E_i$$

be the inclusions, and let

$$\sigma_i: \pi_1^{-1}(p) \times \pi_2^{-1}(p) \rightarrow \pi_i^{-1}(p)$$

be the projections. Then

$$j_i \circ \sigma_i = \rho_i \circ j.$$

So

$$\begin{aligned} j^*(\rho_1^*U_1(\xi_1) \cup \rho_2^*U_2(\xi_2)) &= (\rho_1 \circ j)^*U_1(\xi) \cup (\rho_2 \circ j)^*U_2(\xi) \\ &= \sigma_1^*j_1^*U_1(\xi) \cup \sigma_2^*j_2^*U_2(\xi) \\ &= \sigma_1^*v_1 \cup \sigma_2^*v_2, \end{aligned}$$

where v_i is the generator of $H_c^{n_i}(\pi_i^{-1}(p))$ determined by the orientation on $\pi_i^{-1}(p)$. But $\sigma_1^*v_1 \cup \sigma_2^*v_2$ is easily seen to be the generator of the group $H_c^{n_1+n_2}(\pi_1^{-1}(p) \times \pi_2^{-1}(p))$ determined by the orientation on $\pi_1^{-1}(p) \times \pi_2^{-1}(p)$ (given on page 281). It follows that

$$\rho_1^*U_1(\xi_1) \cup \rho_2^*U_2(\xi_2) = U(\xi), \quad \text{the Thom class of } \xi.$$

So if s_i are sections of ξ_i , then for the obvious section $s_1 + s_2$ of ξ we have

$$\begin{aligned} \chi(\xi) &= (s_1 + s_2)^*U(\xi) = (s_1 + s_2)^*(\rho_1^*U_1(\xi_1) \cup \rho_2^*U_2(\xi_2)) \\ &= [\rho_1 \circ (s_1 + s_2)]^*U_1(\xi_1) \cup [\rho_2 \circ (s_1 + s_2)]^*U_2(\xi_2) \\ &= s_1^*U_1(\xi_1) \cup s_2^*U_2(\xi_2) \\ &= \chi_1(\xi_1) \cup \chi_2(\xi_2). \quad \blacklozenge \end{aligned}$$

Now we are going to look at principal bundles associated with a smooth oriented n -dimensional vector bundle $\xi = \pi: E \rightarrow M$ over a smooth manifold M . We have already considered the principal bundle $F(\xi)$ of frames of E . If we have a Riemannian metric $\langle \cdot, \cdot \rangle$ for ξ , then, as in Chapter 7, we can consider the bundle $O(E)$ of orthonormal frames, which is a principal bundle with group $O(n)$. Since we will be considering only paracompact manifolds M , we know (see pg. II.342) that there is an Ehresmann connection ω on the bundle $O(E)$. Thus ω is a matrix of 1-forms (ω_j^i) on $O(E)$ taking values in $\mathfrak{o}(n)$; the curvature form $\Omega = D\omega$ is a matrix of 2-forms (Ω_j^i) , also with values in $\mathfrak{o}(n)$. [Since we will seldom be working with TM any more, and never with moving frames, we will not resort to any special symbolism to distinguish the forms ω_j^i, Ω_j^i defined on a bundle from those defined for some moving frame.] As we pointed out in Chapter 7, a connection ω on $O(E)$ is equivalent to a covariant differentiation operator on E which is compatible with the metric $\langle \cdot, \cdot \rangle$. In the case of a general bundle ξ over M there will be many connections compatible with the metric $\langle \cdot, \cdot \rangle$; we cannot single one out by asking for a symmetric connection, as this concept makes sense only for the tangent bundle. Since our bundle ξ is oriented, we can also consider the bundle $SO(E)$ of positively oriented orthonormal frames; if X is connected, it is simply one of the two components of $O(E)$. The group of this bundle is $SO(n)$, whose Lie algebra is also $\mathfrak{o}(n)$. So a connection ω on $SO(n)$ again has values in $\mathfrak{o}(n)$, as does the matrix of 2-forms Ω .

Now let us specialize to the case of a smooth oriented n -dimensional vector bundle $\xi = \pi: E \rightarrow M$ over M , where $n = 2m$ is *even*. If $\langle \cdot, \cdot \rangle$ is a Riemannian metric for ξ , and ω is a connection on the corresponding principal bundle $\varpi: SO(E) \rightarrow M$, then we can consider the n -form

$$2m \cdot m! \text{Pf}(\Omega) = \sum_{i_1, \dots, i_n} \varepsilon^{i_1 \dots i_n} \Omega_{i_2}^{i_1} \wedge \dots \wedge \Omega_{i_n}^{i_{n-1}},$$

which is defined *on the bundle* $SO(E)$. The following proof is merely an invariant formulation of an argument presented in the last section.

18. PROPOSITION. There is a unique n -form Λ on M such that

$$\varpi^*(\Lambda) = \sum_{i_1, \dots, i_n} \varepsilon^{i_1 \dots i_n} \Omega_{i_2}^{i_1} \wedge \dots \wedge \Omega_{i_n}^{i_{n-1}} = 2^m m! \text{Pf}(\Omega).$$

PROOF. Given $X_1, \dots, X_n \in M_p$, choose some $u \in \varpi^{-1}(p)$, and let $Y_1, \dots, Y_n \in SO(E)_u$ be tangent vectors with $\varpi_* Y_i = X_i$. Clearly Λ must satisfy

$$\Lambda(X_1, \dots, X_n) = 2^m m! \text{Pf}(\Omega)(Y_1, \dots, Y_n),$$

which proves uniqueness. Existence will be demonstrated once we prove that this Λ is well-defined.

Consider first what happens when we take different tangent vectors $Z_1, \dots, Z_n \in \text{SO}(E)_u$ with $\varpi_* Z_i = X_i$. Since $\varpi_*(Y_i - Z_i) = 0$, all $Y_i - Z_i$ are vertical. But $\Omega(Y, Z) = 0$ if either Y or Z is vertical. So we clearly have

$$\begin{aligned} \text{Pf}(\Omega)(Y_1, \dots, Y_n) &= \text{Pf}(\Omega)(Z_1, Y_2, \dots, Y_n) \\ &= \text{Pf}(\Omega)(Z_1, Z_2, Y_3, \dots, Y_n) = \dots \\ &= \text{Pf}(\Omega)(Z_1, \dots, Z_n). \end{aligned}$$

Thus the definition of Λ does not depend on the choice of the Y_i .

Now suppose we choose a different $\bar{u} \in \varpi^{-1}(p)$. Then $\bar{u} = R_A(u) = u \cdot A$ for some $A \in \text{SO}(n)$, and we can let the $\bar{Y}_i \in \text{SO}(E)_{\bar{u}}$ be $\bar{Y}_i = R_{A*} Y_i$. Then

$$\begin{aligned} \text{Pf}(\Omega)(\bar{Y}_1, \dots, \bar{Y}_n) &= \text{Pf}(\Omega)(R_{A*} Y_1, \dots, R_{A*} Y_n) \\ &= \text{Pf}(R_A^* \Omega)(Y_1, \dots, Y_n) \\ &= \text{Pf}(A^{-1} \Omega A)(Y_1, \dots, Y_n) && \text{by Proposition II.8-11} \\ &= \text{Pf}(\Omega)(Y_1, \dots, Y_n) && \text{by Proposition 9. } \spadesuit \end{aligned}$$

We also have the following result, which is automatic when ξ is the tangent bundle of M .

19. PROPOSITION. The unique n -form Λ of Proposition 18 is closed, $d\Lambda = 0$.

PROOF. Given $X_1, \dots, X_{n+1} \in M_p$, choose $u \in \varpi^{-1}(p)$ and $Y_1, \dots, Y_{n+1} \in \text{SO}(E)_u$ with $\varpi_* Y_i = X_i$. Let hY_i be the horizontal component of Y_i . Then

$$\begin{aligned} d\Lambda(X_1, \dots, X_{n+1}) &= d\Lambda(\varpi_* Y_1, \dots, \varpi_* Y_{n+1}) \\ &= d\Lambda(\varpi_* hY_1, \dots, \varpi_* hY_{n+1}) \\ &= (\varpi^* d\Lambda)(hY_1, \dots, hY_{n+1}) \\ &= d(\varpi^* \Lambda)(hY_1, \dots, hY_{n+1}) \\ &= 2^m m! d\{\text{Pf}(\Omega)\}(hY_1, \dots, hY_{n+1}) \\ &= 2^m m! D\{\text{Pf}(\Omega)\}(Y_1, \dots, Y_{n+1}). \end{aligned}$$

But $D\Omega = 0$ by Bianchi's identity (Theorem II.8-20), and this implies that $D\{\text{Pf}(\Omega)\} = 0$. \spadesuit

In view of Proposition 19, the n -form Λ determines a de Rham cohomology class $[\Lambda] \in H^n(M)$. The form Λ itself depends on the oriented n -dimensional bundle $\xi = \pi: E \rightarrow M$ over M , on the choice of a metric $\langle \cdot, \cdot \rangle$ for ξ , and on the connection ω on the corresponding bundle $\text{SO}(E)$.

20. PROPOSITION. The cohomology class $[\Lambda]$ is independent of the metric $\langle \cdot, \cdot \rangle$ and of the connection ω .

PROOF. Let $\langle \cdot, \cdot \rangle$ and $\langle \cdot, \cdot \rangle'$ be two metrics for ξ . By Corollary 5, the corresponding principle bundles $\text{SO}(E)$ and $\text{SO}'(E)$ are equivalent. If $\tilde{f}: \text{SO}'(E) \rightarrow \text{SO}(E)$ is a fibre preserving diffeomorphism which commutes with the action of $\text{SO}(n)$, and ω is a connection on $\text{SO}(E)$, then $\omega' = \tilde{f}^*\omega$ is a connection on $\text{SO}'(E)$. It is easy to see that the corresponding curvature forms satisfy $\Omega' = \tilde{f}^*\Omega$, so that $\text{Pf}(\Omega') = \tilde{f}^*\text{Pf}(\Omega)$. This implies that the corresponding forms Λ' and Λ are actually equal. To complete the proof it therefore suffices to show that any two connections ω_0, ω_1 on the same principal bundle $\text{SO}(E)$ give rise to forms Λ_0 and Λ_1 whose difference is exact.

Let $q: M \times [0, 1] \rightarrow M$ be the projection $q(p, t) = p$, and consider the bundle $q^*\text{SO}(\xi)$ over $M \times [0, 1]$. There are obvious induced connections $q^*\omega_0$ and $q^*\omega_1$ on $q^*\text{SO}(\xi)$. Let $\tau: M \times [0, 1] \rightarrow [0, 1]$ be the function $\tau(p, t) = t$, and form the connection

$$\omega = (1 - \tau)(q^*\omega_0) + \tau(q^*\omega_1)$$

on $q^*\text{SO}(\xi)$, with connection form Ω , say. If $i_t: M \rightarrow M \times [0, 1]$ is $i_t(p) = (p, t)$, then $i_0^*(\omega)$ can clearly be identified with ω_0 , and $i_1^*(\omega)$ can be identified with ω_1 . By Propositions 18 and 19 (which hold for manifolds-with-boundary as well as for manifolds), there is a closed n -form Λ on $M \times [0, 1]$ which pulls back to $2^m m! \text{Pf}(\Omega)$ on the total space of $q^*\text{SO}(\xi)$. Clearly we must have

$$i_0^*\Lambda = \Lambda_0 \quad \text{and} \quad i_1^*\Lambda = \Lambda_1.$$

Now Theorem I.7-17 (pg. I.224) shows that $\Lambda_1 - \Lambda_0$ is exact. ♦

We thus see that every oriented smooth bundle ξ over M of even fibre dimension n determines a de Rham cohomology class $C(\xi) = [\Lambda] \in H^n(N)$. Clearly $C(\xi) = C(\eta)$ if $\xi \simeq \eta$.

21. PROPOSITION. Let $\xi = \pi: E \rightarrow M$ be a smooth oriented bundle over M of even fibre dimension n , and let $f: M' \rightarrow M$ be a smooth map. Then

$$C(f^*\xi) = f^*(C(\xi)) \in H^n(M').$$

PROOF. Let E' be the total space of $f^*\xi$, and let $\tilde{f}: E' \rightarrow E$ be the bundle map covering f . If $\langle \cdot, \cdot \rangle$ is a metric on E , then $\tilde{f}^*\langle \cdot, \cdot \rangle$ is a metric on E' . Clearly there is an equivalence $\tilde{f}: \text{SO}(E') \rightarrow \text{SO}(E)$ covering f .

$$\begin{array}{ccc} \text{SO}(E') & \xrightarrow{\tilde{f}} & \text{SO}(E) \\ \varpi' \downarrow & & \downarrow \varpi \\ M' & \xrightarrow{f} & M \end{array}$$

If ω is a connection on $\text{SO}(E)$, then $\tilde{f}^*(\omega)$ will be a connection on $\text{SO}(E')$, and it is easy to see that the corresponding connection forms satisfy $\Omega' = \tilde{f}^*\Omega$. Consequently,

$$\text{Pf}(\Omega') = \text{Pf}(\tilde{f}^*\Omega) = \tilde{f}^*\text{Pf}(\Omega).$$

For the n -forms Λ on M given by Proposition 18 we then have

$$\begin{aligned} \varpi'^*(f^*\Lambda) &= \tilde{f}^*\varpi^*\Lambda \\ &= 2^m m! \tilde{f}^*\text{Pf}(\Omega) \\ &= 2^m m! \text{Pf}(\Omega'). \end{aligned}$$

So $f^*\Lambda$ must be the n -form Λ' on M' given by Proposition 18. ♦

We will extend the definition of C by setting $C(\xi) = 0$ when ξ is a smooth oriented bundle of odd fibre dimension. We would like to show that $C(\xi)$ is always some constant times $\chi(\xi)$. If this is the case, then we ought to have an analogue of Theorem 17 for C . And indeed we do.

22. THEOREM. Let $\xi_i = \pi_i: E_i \rightarrow M$ for $i = 1, 2$ be smooth oriented vector bundles over M , of fibre dimensions n_1 and n_2 . If $n_i = 2m_i$, then

$$C(\xi_1 \oplus \xi_2) = \frac{(m_1 + m_2)!}{m_1! m_2!} C(\xi_1) \cup C(\xi_2).$$

(For n_1 or n_2 odd, this just asserts that $C(\xi_1 \oplus \xi_2) = 0$.)

PROOF. Choose Riemannian metrics $\langle \cdot, \cdot \rangle_i$ on ξ_i , and let $\langle \cdot, \cdot \rangle$ be the obvious metric $\langle \cdot, \cdot \rangle_1 \oplus \langle \cdot, \cdot \rangle_2$ on $\xi_1 \oplus \xi_2 = \pi: E \rightarrow M$. Let $\varpi_i: \text{SO}(E_i) \rightarrow M$ and $\varpi: \text{SO}(E) \rightarrow M$ be the corresponding principal bundles. Over M we consider first the principal bundle $\text{SO}(E_1) * \text{SO}(E_2)$, with group $\text{SO}(n_1) \times \text{SO}(n_2) \subset \text{SO}(n_1 + n_2)$, whose fibre over $p \in M$ is just the direct product $\varpi_1^{-1}(p) \times \varpi_2^{-1}(p)$, so that we can regard

$$\text{SO}(E_1) * \text{SO}(E_2) \subset \text{SO}(E).$$

Let $\rho_i: \text{SO}(E_1) * \text{SO}(E_2) \rightarrow \text{SO}(E_i)$ be the obvious projection maps. If ω_i are connections on $\text{SO}(E_i)$, with curvature forms Ω_i , then

$$\rho_1^* \omega_1 \oplus \rho_2^* \omega_2 = \begin{pmatrix} \rho_1^* \omega_1 & 0 \\ 0 & \rho_2^* \omega_2 \end{pmatrix}$$

is a connection $\bar{\omega}$ on $\text{SO}(E_1) * \text{SO}(E_2)$, with curvature form

$$\bar{\Omega} = \rho_1^* \Omega_1 \oplus \rho_2^* \Omega_2 = \begin{pmatrix} \rho_1^* \Omega_1 & 0 \\ 0 & \rho_2^* \Omega_2 \end{pmatrix}.$$

The connection $\bar{\omega}$ can be extended uniquely to a connection $\tilde{\omega}$ on $\text{SO}(E)$ [the requirement $\tilde{\omega}(\sigma(M)) = M$ determines $\tilde{\omega}$ at the new vertical vectors, hence $\tilde{\omega}$ is determined at all points of $\text{SO}(E_1) * \text{SO}(E_2)$, and then at all points of $\text{SO}(E)$ by the requirement $\tilde{\omega}(R_A^* Y) = \text{Ad}(A^{-1})\tilde{\omega}(Y)$]. At any point $e \in \text{SO}(E_1) * \text{SO}(E_2)$ the horizontal vectors for $\tilde{\omega}$ are the same as for $\bar{\omega}$, so at e we have

$$\begin{aligned} \tilde{\Omega} &= \bar{\Omega} \quad [\text{on tangent vectors to } \text{SO}(E_1) * \text{SO}(E_2)] \\ \implies \text{Pf}(\tilde{\Omega}) &= \text{Pf}(\bar{\Omega}) = \text{Pf}(\rho_1^* \Omega_1) \wedge \text{Pf}(\rho_2^* \Omega_2) \quad \text{by Corollary 13} \\ &= \rho_1^* \text{Pf}(\Omega_1) \wedge \rho_2^* \text{Pf}(\Omega_2). \end{aligned}$$

So if Λ_i, Λ are the forms given by Proposition 18, then at e we must have

$$\begin{aligned} \varpi^* \Lambda &= 2^{m_1+m_2} (m_1 + m_2)! \text{Pf}(\tilde{\Omega}) \quad [\text{on tangent vectors to } \text{SO}(E_1) * \text{SO}(E_2)] \\ &= \frac{(m_1 + m_2)!}{m_1! m_2!} 2^{m_1} m_1! \rho_1^* \text{Pf}(\Omega_1) \wedge 2^{m_2} m_2! \rho_2^* \text{Pf}(\Omega_2) \\ &= \frac{(m_1 + m_2)!}{m_1! m_2!} \rho_1^* \varpi_1^* \Lambda_1 \wedge \rho_2^* \varpi_2^* \Lambda_2 \\ &= \frac{(m_1 + m_2)!}{m_1! m_2!} \varpi^* \Lambda_1 \wedge \varpi^* \Lambda_2. \end{aligned}$$

This implies that

$$\Lambda = \frac{(m_1 + m_2)!}{m_1! m_2!} \Lambda_1 \wedge \Lambda_2. \quad \spadesuit$$

Applying Theorem 22 when $n_1 = 1$, we immediately deduce that the class C has a property which we have already mentioned for χ (pg. I.445):

23. COROLLARY. If the oriented bundle $\xi = \pi: E \rightarrow M$ has a nowhere zero section s , then

$$C(\xi) = 0.$$

PROOF. Let $E_1 \subset E$ be

$$\bigcup_{p \in M} \mathbb{R} \cdot s(p),$$

and let $E_2 \subset E$ be the orthogonal complement

$$\bigcup_{p \in M} (\mathbb{R} \cdot s(p))^\perp$$

with respect to some Riemannian metric on E . Then $\xi_1 = \pi_1|E_1: E_1 \rightarrow M$ is an oriented 1-dimensional bundle, so $\xi_2 = \pi_2|E_2: E_2 \rightarrow M$ is also an oriented bundle (since ξ is oriented). Clearly $\xi \simeq \xi_1 \oplus \xi_2$. So Theorem 22 shows that $C(\xi) = 0$. ♦

But this fact practically characterizes χ :

24. COROLLARY. If $\xi = \pi: E \rightarrow M$ is a smooth oriented vector bundle of fibre dimension n over a compact oriented manifold M , then the class $C(\xi) \in H^n(M)$ is a multiple of the Euler class $\chi(\xi)$.

PROOF. Let S be the sphere bundle $S = \{e \in E : \langle e, e \rangle = 1\}$ formed with respect to some Riemannian metric on E , and let $\pi_0: S \rightarrow M$ be the restriction $\pi|S$. As we pointed out in section 2, the bundle $\pi_0^*\xi$ has a nowhere zero section. So Corollary 23 gives

$$\begin{aligned} 0 &= C(\pi_0^*\xi) \\ &= \pi_0^*C(\xi) \quad \text{by Proposition 21.} \end{aligned}$$

But Theorem I.11-31 says that a class $\alpha \in H^n(M)$ satisfies $\pi_0^*\alpha = 0$ if and only if α is a multiple of $\chi(\xi)$. ♦

If we apply this corollary to the tangent bundle of a compact oriented manifold M of even dimension n , we find that the class $C(TM) \in H^n(M)$ is some multiple of the Euler class $\chi(TM)$. This statement is not very interesting, since $H^n(M)$ is 1-dimensional (all it tells us is that $C(TM) = 0$ if $\chi(TM) = 0$). But we obtain a statement which is interesting when we apply the corollary to the universal bundle:

25. COROLLARY. For every even n , there is a “universal constant” A_n such that

$$C(\xi) = A_n \cdot \chi(\xi)$$

for *all* smooth oriented n -dimensional bundles ξ over compact oriented manifolds.

PROOF. Consider the bundles $\tilde{\gamma}^n(\mathbb{R}^N)$, for $N > n$. By Corollary 24, there are constants $A_{n,N}$ such that

$$(1) \quad C(\tilde{\gamma}^n(\mathbb{R}^N)) = A_{n,N} \cdot \chi(\tilde{\gamma}^n(\mathbb{R}^N)) \in H^n(\tilde{G}_n(\mathbb{R}^N)).$$

If $\alpha: \tilde{G}_n(\mathbb{R}^N) \rightarrow \tilde{G}_n(\mathbb{R}^M)$ is the natural inclusion, then

$$\alpha^*(\tilde{\gamma}^n(\mathbb{R}^M)) \simeq \tilde{\gamma}^n(\mathbb{R}^N),$$

so Propositions 15 and 21 give

$$(2) \quad C(\tilde{\gamma}^n(\mathbb{R}^N)) = \alpha^* C(\tilde{\gamma}^n(\mathbb{R}^M))$$

$$(3) \quad \chi(\tilde{\gamma}^n(\mathbb{R}^N)) = \alpha^* \chi(\tilde{\gamma}^n(\mathbb{R}^M)).$$

Equations (1)–(3) give

$$A_{n,N} \cdot \chi(\tilde{\gamma}^n(\mathbb{R}^N)) = A_{n,M} \cdot \chi(\tilde{\gamma}^n(\mathbb{R}^N)).$$

Since $\chi(\tilde{\gamma}^n(\mathbb{R}^N)) \neq 0$ by Corollary 16, this implies that $A_{n,N} = A_{n,M}$ for all $N, M > n$. Denoting this common number by A_n , we have

$$(*) \quad C(\tilde{\gamma}^n(\mathbb{R}^N)) = A_n \cdot \chi(\tilde{\gamma}^n(\mathbb{R}^N)).$$

Now by Theorem 8 any smooth oriented n -dimensional bundle ξ over a compact manifold M is equivalent to $f^*\tilde{\gamma}^n(\mathbb{R}^N)$ for some smooth map $f: M \rightarrow \tilde{G}_n(\mathbb{R}^N)$. Thus

$$\begin{aligned} C(\xi) &= C(f^*\tilde{\gamma}^n(\mathbb{R}^N)) \\ &= f^*C(\tilde{\gamma}^n(\mathbb{R}^N)) && \text{by Proposition 21} \\ &= A_n \cdot f^*\chi(\tilde{\gamma}^n(\mathbb{R}^N)) && \text{by } (*) \\ &= A_n \cdot \chi(\xi) && \text{by Proposition 15. } \spadesuit \end{aligned}$$

To see what this universal constant A_n is, we merely have to compute it in some convenient special case:

26. THEOREM (THE GAUSS-BONNET-CHERN THEOREM). For even $n = 2m$, the constant A_n is

$$\begin{aligned} A_n &= \frac{n!}{2} \cdot \text{volume of the unit } n\text{-sphere } S^n \\ &= \frac{n!}{2} \cdot \frac{\pi^m 2^{n+1} m!}{n!} = \pi^m 2^n m!. \end{aligned}$$

Consequently, if $(M, \langle \ , \ \rangle)$ is a compact oriented manifold of even dimension $n = 2m$, then

$$\begin{aligned} \int_M K_n dV &= \frac{1}{2} \text{volume of } S^n \cdot \chi(M) \\ &= \frac{\pi^m 2^n m!}{n!} \chi(M). \end{aligned}$$

PROOF. Let ξ be the tangent bundle TM of a compact oriented Riemannian n -manifold M . On page 284 we have a formula for $K_n dV$ (in this formula the Ω_j^i are the curvature forms for some positively oriented orthonormal moving frame) which clearly implies that the form Λ given by Proposition 18 for the bundle $\text{SO}(\xi) = \text{SO}(TM)$ is

$$\Lambda = n! K_n dV.$$

So if μ is the fundamental class of M , then

$$\begin{aligned} \left(\int_M K_n dV \right) \cdot \mu &= \frac{1}{n!} \left(\int_M \Lambda \right) \cdot \mu = \frac{1}{n!} C(\xi) \\ &= \frac{A_n}{n!} \chi(\xi) \\ &= \frac{A_n}{n!} \chi(M) \cdot \mu \quad \text{by Theorem I.11-30.} \end{aligned}$$

Hence

$$(1) \quad \int_M K_n dV = \frac{A_n}{n!} \chi(M).$$

Taking $M = S^n$ in (1), with $K_n = 1$, we have

$$\text{volume } S^n = \frac{A_n}{n!} \chi(S^n) = \frac{2A_n}{n!}$$

$$\implies A_n = \frac{n!}{2} \text{volume } S^n = \frac{n!}{2} \frac{\pi^m 2^{n+1} m!}{n!} = \pi^m 2^n m!, \quad \text{by Problem I.9-14.}$$

Substituting this value of A_n back into (1) we now have, for any M ,

$$\int_M K_n dV = \frac{\pi^m 2^n m!}{n!} \chi(M). \quad \spadesuit$$

5. THE CONCEPT OF CHARACTERISTIC CLASSES

Our proof of the generalized Gauss-Bonnet theorem made essential use of the fact that both the Euler class $\chi(\xi)$ and the class $C(\xi)$ are “natural”: for a bundle $\xi = \pi: E \rightarrow M$ and a map $f: M' \rightarrow M$ we have

$$\chi(f^*\xi) = f^*(\chi(\xi)) \quad \text{and} \quad C(f^*\xi) = f^*(C(\xi)).$$

This suggests that we might obtain greater insight into the theorem by trying to find out what *all* such natural classes are. To be precise, we define a **characteristic class of dimension k for smooth n -dimensional bundles** to be a function C which associates to each smooth n -dimensional bundle $\xi = \pi: E \rightarrow M$ an element

$$C(\xi) \in H^k(M),$$

with the following property: if $\xi' = \pi': E' \rightarrow M'$ is another smooth n -dimensional bundle, and (\tilde{f}, f) is a smooth bundle map from ξ' to ξ , then

$$C(\xi') = f^*(C(\xi)) \in H^n(M').$$

Here is an equivalent formulation: $C(\xi) = C(\eta)$ if $\xi \simeq \eta$, and for every smooth n -dimensional bundle $\xi = \pi: E \rightarrow M$ and smooth map $f: M' \rightarrow M$ we have

$$C(f^*\xi) = f^*(C(\xi)).$$

We can also define characteristic classes for oriented bundles; these are the characteristic classes that we will actually investigate. What we would like to do is to find out what *all* these characteristic classes are. This question might look hopeless, were it not for the universal bundles $\tilde{\gamma}^n(\mathbb{R}^N)$. Notice that a characteristic class C of dimension k for smooth n -dimensional bundles gives us, in particular, certain elements

$$c_N = C(\tilde{\gamma}^n(\mathbb{R}^N)) \in H^k(\tilde{G}_n(\mathbb{R}^N)).$$

If

$$\alpha_{N,N'}: \tilde{G}_n(\mathbb{R}^N) \rightarrow \tilde{G}_n(\mathbb{R}^{N'}) \quad N' > N$$

is the natural map, then

$$\alpha_{N,N'}^*(\tilde{\gamma}^n(\mathbb{R}^{N'})) \simeq \tilde{\gamma}^n(\mathbb{R}^N) \implies \alpha_{N,N'}^*c_{N'} = c_N.$$

Conversely, suppose we are given classes

$$c_N \in H^k(\tilde{G}_n(\mathbb{R}^N))$$

satisfying the compatibility condition

$$(C) \quad \alpha_{N,N'}^* c_{N'} = c_N \quad \text{for } N' > N.$$

Since, by Theorem 8, any oriented n -dimensional bundle ξ over a compact M is equivalent to $f^* \tilde{\gamma}^n(\mathbb{R}^N)$ for some $f: M \rightarrow \tilde{G}_n(\mathbb{R}^N)$, we can *define*

$$C(\xi) = f^* c_N.$$

Then $C(\xi)$ is well-defined, for if we have

$$f: M \rightarrow \tilde{G}_n(\mathbb{R}^N) \quad \text{and} \quad g: M \rightarrow \tilde{G}_n(\mathbb{R}^{N'})$$

with

$$f^* \tilde{\gamma}^n(\mathbb{R}^N) \simeq \xi \simeq g^* \tilde{\gamma}^n(\mathbb{R}^{N'}),$$

then the compositions

$$\alpha_{N,N''} \circ f, \quad \alpha_{N',N''} \circ g, \quad N'' \geq 2N, 2N'$$

are homotopic, so

$$\begin{aligned} f^* c_N &= f^* \alpha_{N,N''}^* c_{N''} && \text{by condition (C)} \\ &= (\alpha_{N,N''} \circ f)^* c_{N''} \\ &= (\alpha_{N',N''} \circ g)^* c_{N''} \\ &= g^* c_{N'}. \end{aligned}$$

Moreover, if $h: M' \rightarrow M$ is a smooth map, then

$$\begin{aligned} C(h^* \xi) &= C(h^* f^* \tilde{\gamma}^n(\mathbb{R}^N)) \\ &= h^* f^* c_N \\ &= h^* C(\xi). \end{aligned}$$

So we could just as well define a **characteristic class of dimension k for smooth oriented n -dimensional bundles** to be a collection of classes

$$c_N \in H^k(\tilde{G}_n(\mathbb{R}^N))$$

satisfying

$$(C) \quad \alpha_{N,N'}^* c_{N'} = c_N \quad \text{for } N' > N.$$

Now the problem doesn't seem quite so formidable; the main task seems to be the computation of $H^k(\tilde{G}_n(\mathbb{R}^N))$. As a matter of fact, it will turn out that the maps

$$\alpha_{N,N'}^*: H^k(\tilde{G}_n(\mathbb{R}^{N'})) \rightarrow H^k(\tilde{G}_n(\mathbb{R}^N))$$

are *isomorphisms* for $N, N' > n + k$. So a characteristic class of dimension k will be just the same as an element of $H^k(\tilde{G}_n(\mathbb{R}^N))$, for any $N > n + k$.

[If we were willing to work with singular cohomology, say, on spaces which are not manifolds, then we could define a characteristic class to be simply an element of the k -dimensional cohomology of the space $\tilde{G}_n(\mathbb{R}^\infty)$, the oriented version of the space $G_n(\mathbb{R}^\infty)$ defined on page 280.]

Now the calculation of cohomology groups is really the business of algebraic topologists, and all sorts of machinery has been used for computing characteristic classes [for all coefficient groups]. Rather than using any of the standard methods from this field, we will compute characteristic classes by purely differential geometric methods, making essential use of the fact that the Grassmannians are coset spaces of Lie groups. Although the procedure is quite involved, along the way we will get to look at several topics which are interesting in their own right. Moreover, the analysis will motivate the definition, in section 10, of one of the famous constructions in differential geometry. Finally, the Pfaffian will arise in a completely natural way.

6. THE COHOMOLOGY OF HOMOGENEOUS SPACES

By a **homogeneous space** we will mean a left coset space G/H , where G is a Lie group and H is a closed subgroup. We let $\pi: G \rightarrow G/H$ be the natural projection $\pi(a) = aH$, and we give G/H the quotient topology: a set $\mathcal{U} \subset G/H$ is open if and only if $\pi^{-1}(\mathcal{U}) \subset G$ is open. It is an easy exercise to show that G/H is Hausdorff. Notice also that if $V \subset G$ is any set, then

$$\begin{aligned} \pi(a) \in \pi(V) &\iff aH \in \{bH : b \in V\} \\ &\iff aH = bH && \text{for some } b \in V \\ &\iff a \in bH && \text{for some } b \in V. \end{aligned}$$

So

$$\pi^{-1}(\pi(V)) = V \cdot H = \bigcup_{h \in H} V \cdot h.$$

This shows that $\pi(V) \subset G/H$ is open if $V \subset G$ is open; thus π is an open map, as well as a continuous one.

For every $a \in G$ we have a map $\mathbf{L}_a: G/H \rightarrow G/H$ given by $\mathbf{L}_a(bH) = abH$ (the notation $L_a: G \rightarrow G$ will be reserved for the map given by $L_a(b) = ab$). Obviously the diagram

$$\begin{array}{ccc} G & \xrightarrow{\pi} & G/H \\ L_a \downarrow & & \downarrow \mathbf{L}_a \\ G & \xrightarrow{\pi} & G/H \end{array}$$

commutes, which implies that \mathbf{L}_a is continuous; more generally, it is easy to see that the map

$$G \times G/H \rightarrow G \quad \text{given by} \quad (a, bH) \mapsto abH$$

is continuous.

In this section we will show that G/H is a manifold, and we will find a method of computing the de Rham cohomology $H^*(G/H)$ when G is compact and connected. More precisely, we will reduce the determination of the de Rham cohomology to purely algebraic calculations involving the Lie algebras of G and H . In section 9 we will carry out a sufficient portion of the algebraic calculations for the Grassmannians $\tilde{G}_n(\mathbb{R}^N) = \text{SO}(N)/\text{SO}(n) \times \text{SO}(N-n)$ to determine all characteristic classes for oriented bundles.

We already know, from Theorem I.10-15, that the closed subgroup H of G is a Lie subgroup; in fact, there is a C^∞ structure on H , with the relative topology, that makes it a Lie subgroup of G .

27. PROPOSITION. Let G be a Lie group of dimension n , and H a closed subgroup of dimension d . Then G/H is a topological manifold of dimension $n-d$, and there is a unique C^∞ structure on G/H such that

- (i) $\pi: G \rightarrow G/H$ is C^∞
- (ii) For every point of G/H there is a neighborhood \mathcal{U} and a C^∞ section $s: \mathcal{U} \rightarrow G$ (a map $s: \mathcal{U} \rightarrow G$ satisfying $\pi \circ s = \text{identity}$).

PROOF. From the proof of Theorem I.10-15 we know that there is a coordinate system (x, U) around e with

$$\begin{aligned} x(e) &= 0 \\ x(U) &= (-\varepsilon, \varepsilon) \times \cdots \times (-\varepsilon, \varepsilon), \end{aligned}$$

such that each slice

$$x^{d+1} = \text{constant}, \dots, x^n = \text{constant}$$

is an open subset of some left coset of H . In particular, the slice S_e through e is an open subset of H . Since H has the relative topology, this slice is of the form $V \cap H$ for some open set V . So by choosing ε smaller, if necessary, we can assume that

$$U \cap H = S_e.$$

We will now show that we can arrange for all slices to lie on different cosets of H . Choose $\varepsilon_1, \varepsilon_2 < \varepsilon$ so that the sets U_i with $x(U_i) = (-\varepsilon_i, \varepsilon_i) \times \cdots \times (-\varepsilon_i, \varepsilon_i)$ satisfy

$$U_1^{-1} \cdot U_1 \subset U_2, \quad U_2 \cdot U_2 \subset U.$$

If $a, b \in U_1$ satisfy $aH = bH$, then

$$b^{-1}a \in U_2 \cap H = U_2 \cap S_e \implies a \in b \cdot (U_2 \cap S_e).$$

Now $b \cdot (U_2 \cap S_e)$ is connected and lies in U , so it lies in a single slice. This shows that a and b lie in the same slice. Equivalently, different slices of U_1 lie in different cosets, as desired. For convenience, we assume that U_1 is our original U .

If we now consider the “cross-section” $C \subset U$ defined by

$$C = \{a \in U_1 : x^1(a) = \cdots = x^d(a) = 0\},$$

we see that

$$\pi|C : C \rightarrow G/H$$

is one-one, with image $\pi(C) = \pi(U)$, which is open in G/H . Since π is both continuous and open, the map $\pi|C$ is a homeomorphism. The inverse homeomorphism

$$\chi = (\pi|C)^{-1} : \pi(U) \rightarrow C$$

can be regarded as a map into \mathbb{R}^{n-d} ; we will use this map as a coordinate system around the coset H in G/H . For every $a \in G$ we let χ_a be the composition

$$\pi(a \cdot U) \xrightarrow{\mathbf{L}_{a^{-1}}} \pi(U) \xrightarrow{(\pi|C)^{-1}} C.$$

Then for $a, b \in G$ we have

$$\begin{aligned} \chi_a \circ \chi_b^{-1} &= (\pi|C)^{-1} \circ \mathbf{L}_{a^{-1}} \circ \mathbf{L}_b \circ \pi|C \\ &\text{on the set } W = \chi_b(\pi(a \cdot U) \cap \pi(b \cdot U)). \end{aligned}$$

For $c \in C$ we have

$$\mathbf{L}_{a^{-1}} \mathbf{L}_b(\pi|C)(c) = a^{-1}bcH,$$

and it is easy to check that if $c \in W$, then

$$(\pi|C)^{-1}L_{a^{-1}}L_b(\pi|C)(c) = a^{-1}bc.$$

This shows that χ_a and χ_b are C^∞ related, so the collection $\{\chi_a\}$ determines a C^∞ structure on G/H .

To show that $\pi: G \rightarrow G/H$ is C^∞ at a , we have to show that the map

$$(-\varepsilon, \varepsilon) \times \cdots \times (-\varepsilon, \varepsilon) \xrightarrow{L_a \circ x^{-1}} a \cdot U \xrightarrow{\pi} \pi(a \cdot U) \xrightarrow{\chi_a} C$$

is C^∞ . This map is

$$(-\varepsilon, \varepsilon) \times \cdots \times (-\varepsilon, \varepsilon) \xrightarrow{L_a \circ x^{-1}} a \cdot U \xrightarrow{\pi} \pi(a \cdot U) \xrightarrow{L_{a^{-1}}} \pi(U) \xrightarrow{(\pi|C)^{-1}} C,$$

which equals

$$(-\varepsilon, \varepsilon) \times \cdots \times (-\varepsilon, \varepsilon) \xrightarrow{x^{-1}} U \xrightarrow{\pi} \pi(U) \xrightarrow{(\pi|C)^{-1}} C;$$

the latter map is just projection on the last $n - d$ coordinates.

To prove (ii), we note that

$$s = L_a \circ \chi_a: \pi(a \cdot U) \rightarrow G$$

satisfies $\pi \circ s = \text{identity}$.

Uniqueness is left to the reader. ♦

The quotient topology on G/H has the property that $f: G/H \rightarrow X$ is continuous if and only if $f \circ \pi: G \rightarrow X$ is continuous. The C^∞ structure on G/H given by Proposition 27 now has the property that $f: G/H \rightarrow M$ is C^∞ if and only if $f \circ \pi: G \rightarrow M$ is C^∞ . In fact, if $f \circ \pi$ is C^∞ , and s is a C^∞ section on $\mathcal{U} \subset G/H$, then $f|_{\mathcal{U}} = f \circ \pi \circ s$ is C^∞ . It is also easy to see that the map

$$G \times G/H \rightarrow G/H, \quad (a, bH) \mapsto abH$$

is C^∞ : if $s: \mathcal{U} \rightarrow G$ is a section, then on $G \times \mathcal{U}$ this map equals

$$G \times \mathcal{U} \xrightarrow{\text{identity} \times s} G \times G \xrightarrow{\cdot} G \xrightarrow{\pi} G/H.$$

In particular, each $L_a: G/H \rightarrow G/H$ is C^∞ . Finally, we recall that in section 3 we defined a C^∞ structure on $\tilde{G}_n(\mathbb{R}^N)$ geometrically. It is easily checked that

this C^∞ structure satisfies (i) and (ii) when we consider $\tilde{G}_n(\mathbb{R}^N)$ as the quotient space $SO(N)/SO(n) \times SO(N-n)$.

For the remainder of this section we will assume that G is a *compact, connected* Lie group, with Lie algebra \mathfrak{g} , and that H is a closed subgroup with Lie algebra $\mathfrak{h} \subset \mathfrak{g}$. Before we consider the cohomology of G/H , a few preliminaries are needed. Recall (Proposition I.10-20) that any left invariant n -form σ^n on G is also right invariant. We will choose σ^n to be the unique bi-invariant n -form with $\int_G \sigma^n = 1$; as before, for a function $f: G \rightarrow \mathbb{R}$ we often write

$$\int_G f \sigma^n \quad \text{as} \quad \int_G f(a) da.$$

For every $a \in G$ we define the map $\text{Ad}(a): \mathfrak{g} \rightarrow \mathfrak{g}$ by

$$\text{Ad}(a) = (L_a \circ R_{a^{-1}})_*: \mathfrak{g} \rightarrow \mathfrak{g}.$$

When G is a subgroup of $GL(n, \mathbb{R})$, so that \mathfrak{g} is a subspace of $\mathfrak{gl}(n, \mathbb{R}) = n \times n$ matrices, we have the simple formula (Problem I.10-19 or pg. II.309)

$$\text{Ad}(A)M = AMA^{-1} \quad \text{for } A \in G, \quad M \in \mathfrak{g}.$$

Finally, recall that there is a bi-invariant Riemannian metric $\langle \cdot, \cdot \rangle$ on the compact Lie group G . When $G = O(n)$ we can describe such a metric explicitly as follows. For $M, P \in \mathfrak{o}(n) = \text{skew-symmetric } n \times n \text{ matrices}$, let

$$\langle M, P \rangle = \text{trace } MP^t = \sum_{i,j} M_{ij} P_{ij}.$$

For every $A \in O(n)$ we have

$$\begin{aligned} \langle \text{Ad}(A)M, \text{Ad}(A)P \rangle &= \text{trace } AMA^{-1} \cdot (APA^{-1})^t \\ &= \text{trace } A(MP^t)A^{-1} \\ &= \text{trace } MP^t = \langle M, P \rangle. \end{aligned}$$

So if we extend $\langle \cdot, \cdot \rangle$ to $O(n)$ by left invariance, then it will also be right invariant.

Now consider a k -form ω on G/H . We say that ω is **invariant** if $L_a^* \omega = \omega$ for all $a \in G$. For any k -form ω on G/H we can define a new k -form

$$\omega' = \int_G (a \mapsto L_a^* \omega) \sigma^n = \int_G L_a^* \omega da;$$

this equation really means that

$$\omega'(X_1, \dots, X_k) = \int_G [a \mapsto \mathbf{L}_a^* \omega(X_1, \dots, X_k)] \sigma^n = \int_G \mathbf{L}_a^* \omega(X_1, \dots, X_k) da.$$

It follows easily from left invariance of σ^n that ω' is invariant. More generally, given a smooth family $a \mapsto \eta_a$ of k -forms on G/H , where η_a is defined for all a in an open set $U \subset G$, we can form

$$\int_U (a \mapsto \eta_a) \sigma^n = \int_U \eta_a da,$$

which is a k -form on all of G/H . If X_1, \dots, X_k, Y are vector fields on G/H , then

$$Y \left(\int_U \eta_a(X_1, \dots, X_k) da \right) = \int_U Y(\eta_a(X_1, \dots, X_k)) da;$$

this follows from Proposition 9-10 when we choose an integral curve c for Y and let

$$\Gamma(u) = [a \mapsto \eta_a(X_1(c(u)), \dots, X_k(c(u)))] \cdot \sigma^n.$$

Using Theorem I.7-13, we then see that

$$d \left(\int_U (a \mapsto \eta_a) \sigma^n \right) = \int_U (a \mapsto d\eta_a) \sigma^n;$$

in simpler, but rather confusing, notation, we have

$$d \left(\int_U \eta_a da \right) = \int_U d\eta_a da.$$

28. PROPOSITION. If ω is a closed k -form on G/H , and

$$\omega' = \int_G \mathbf{L}_a^* \omega da,$$

then $\omega - \omega'$ is exact.

PROOF. For a fixed $a \in G$, the map $\mathbf{L}_a: G/H \rightarrow G/H$ is smoothly homotopic to the identity map $\mathbf{L}_e: G/H \rightarrow G/H$. In fact, we can write $a = \exp X$ for some $X \in \mathfrak{g}$ (Problem I.10-27), and consider the smooth family of maps $\mathbf{L}_{\exp tX}$ from \mathbf{L}_e to \mathbf{L}_a . It follows from Theorem I.8-13 that there is a $(k-1)$ -form η_a with

$$(*) \quad \omega - \mathbf{L}_a^* \omega = d\eta_a.$$

Moreover, the proof of this Theorem gives us an explicit formula for η_a .

Now let $E \subset \mathfrak{g}$ be an open set on which \exp is a diffeomorphism. From the explicit description of η_a we see that η_a varies smoothly with a for all $a \in \exp(E)$. So we can integrate equation (*) over $\exp(E)$, to obtain

$$[\text{volume } \exp(E)] \cdot \omega - \int_{\exp(E)} \mathbf{L}_a^* \omega \, da = d \left(\int_{\exp(E)} \eta_a \, da \right).$$

(Notice that the three forms in this equation are each defined on all of G/H .) But by Theorem 8-31, we can choose E so that $G - \exp(E)$ has measure 0. Then our equation becomes

$$\omega - \int_G \mathbf{L}_a^* \omega \, da = d \left(\int_{\exp(E)} \eta_a \, da \right). \spadesuit$$

On the other hand, it is even easier to show

29. PROPOSITION. If ω is a form on G/H which is invariant and exact, then ω is actually the exterior derivative of some invariant form.

PROOF. If $\omega = d\eta$, then

$$\begin{aligned} \omega &= \int_G \mathbf{L}_a^* \omega \, da = \int_G \mathbf{L}_a^* (d\eta) \, da \\ &= d \left(\int_G \mathbf{L}_a^* \eta \, da \right) = d\eta', \end{aligned}$$

where η' is invariant. \spadesuit

From Propositions 28 and 29 we immediately have

30. THEOREM. The k -dimensional de Rham cohomology $H^k(G/H)$ of G/H is naturally isomorphic to

$$H^k(G/H) \approx \frac{\text{closed invariant } k\text{-forms on } G/H}{\{d\eta : \eta \text{ an invariant } (k-1)\text{-form on } G/H\}}.$$

The cup product in $H^*(G/H)$ corresponds to \wedge under this isomorphism.

What really makes this result important is the fact that we can describe the invariant k -forms on G/H in terms of the left invariant forms on G . Note that the map $\text{Ad}(a): \mathfrak{g} \rightarrow \mathfrak{g}$ induces maps $\text{Ad}(a)^*: \Omega^k(\mathfrak{g}) \rightarrow \Omega^k(\mathfrak{g})$; the map $\text{Ad}(a)^*$ is just $(L_a \circ R_{a^{-1}})^*$ at e . A k -form η on G will be called **$\text{Ad}(H)$ -invariant** if

$$\text{Ad}(a)^*\eta(e) = \eta(e) \quad \text{for all } a \in H.$$

We say that η **annihilates** \mathfrak{h} if $\eta(e)(X_1, \dots, X_k) = 0$ whenever some $X_i \in \mathfrak{h}$.

31. LEMMA. If $\pi: G \rightarrow G/H$ is the natural projection, then the map $\omega \mapsto \pi^*\omega$ is a one-one correspondence between the invariant k -forms on G/H and the left invariant, $\text{Ad}(H)$ -invariant k -forms on G which annihilate \mathfrak{h} .

PROOF. If ω is invariant, then for all $a \in G$ we have

$$L_a^*\pi^*\omega = \pi^*L_a^*\omega = \pi^*\omega,$$

so $\pi^*\omega$ is left invariant. If $X_1, \dots, X_k \in \mathfrak{g}$ and some $X_i \in \mathfrak{h}$, then $\pi_*X_i = 0$, so

$$(\pi^*\omega)(X_1, \dots, X_k) = \omega(\pi_*X_1, \dots, \pi_*X_i, \dots, \pi_*X_k) = 0;$$

thus $\pi^*\omega$ annihilates \mathfrak{h} . Finally, if $a \in H$, then the map

$$\pi \circ L_a \circ R_{a^{-1}}: G \rightarrow G/H$$

is

$$b \mapsto aba^{-1}H = abH = L_a(bH) = L_a(\pi(b)),$$

so we have

$$(1) \quad \pi \circ L_a \circ R_{a^{-1}} = L_a \circ \pi;$$

consequently,

$$(L_a \circ R_{a^{-1}})^*\pi^*\omega = \pi^*L_a^*\omega = \pi^*\omega,$$

so $\pi^*\omega$ is $\text{Ad}(H)$ -invariant.

Conversely, suppose that the k -form η on G is left invariant, $\text{Ad}(H)$ -invariant, and annihilates \mathfrak{h} . The map $\pi_*: \mathfrak{g} \rightarrow (G/H)_H$ from \mathfrak{g} to the tangent space of G/H at the coset H has kernel precisely \mathfrak{h} , and therefore induces an isomorphism

$$\pi_*: \mathfrak{g}/\mathfrak{h} \rightarrow (G/H)_H.$$

We can consider $\eta(e) \in \Omega^k(\mathfrak{g}/\mathfrak{h})$, since η annihilates \mathfrak{h} , so there is a unique $\omega(H) \in \Omega^k((G/H)_H)$ with

$$(2) \quad \pi^*(\omega(H)) = \eta(e) \in \Omega^k(\mathfrak{g}/\mathfrak{h}).$$

Define ω on G/H by

$$\omega(aH) = L_{a^{-1}}^* \omega(H).$$

To show that ω is well-defined, consider $a, b \in G$ with $aH = bH$. Then $c = a^{-1}b \in H$. So by (1),

$$\begin{aligned} \pi^* L_c^* \omega(H) &= (L_c \circ R_{c^{-1}})^* \pi^* \omega(H) \\ &= (L_c \circ R_{c^{-1}})^* \eta(e) \\ &= \eta(e), \end{aligned}$$

since η is $\text{Ad}(H)$ -invariant. Since $\omega(H)$ is the unique element satisfying (2), we conclude that

$$\begin{aligned} \omega(H) &= L_c^* \omega(H) = (L_{a^{-1}} \circ L_b)^* \omega(H) \\ &= L_b^* (L_{a^{-1}}^* \omega(H)), \end{aligned}$$

and hence

$$L_{b^{-1}}^* \omega(H) = L_{a^{-1}}^* \omega(H),$$

as desired. Clearly ω is invariant. Moreover, for all $a \in G$ we have

$$\begin{aligned} \eta(a) &= L_{a^{-1}}^* \eta(e) \quad \text{since } \eta \text{ is left invariant} \\ &= L_{a^{-1}}^* \pi^* \omega(H) \\ &= \pi^* L_{a^{-1}}^* \omega(H) \\ &= \pi^*(\omega(aH)) \\ &= (\pi^* \omega)(a). \quad \blacklozenge \end{aligned}$$

Notice that in the first part of the proof we showed that for all $a \in H$, the given ω satisfies $(L_a \circ R_{a^{-1}})^* \pi^* \omega = \pi^* \omega$ at all points, not just at e . Since any left invariant form η on G which annihilates \mathfrak{h} and satisfies $(L_a \circ R_{a^{-1}})^* \eta(e) = \eta(e)$ is $\pi^* \omega$ for an invariant form ω on G/H , it follows that such an η satisfies $(L_a \circ R_{a^{-1}})^* \eta = \eta$ at all points, for all $a \in H$; this conclusion does not follow just from the fact that η is left invariant—we need to know that η annihilates \mathfrak{h} . Similarly, but more important, since $d\omega$ is clearly invariant for all invariant ω on G/H , it follows that if η is left invariant, $\text{Ad}(H)$ -invariant, and annihilates \mathfrak{h} ,

then $d\eta$ has these same properties [but the fact that η annihilates \mathfrak{h} , for example, does not by itself imply that $d\eta$ annihilates \mathfrak{h}].

We are now ready to give a completely algebraic description of $H^k(G/H)$. Notice first that if ω is a left invariant k -form, and $X_1, \dots, X_{k+1} \in \mathfrak{g}$, then $d\omega(X_1, \dots, X_{k+1})$ can be computed by applying Theorem I.7-13 to the left invariant vector fields \tilde{X}_i extending X_i . The terms

$$\omega(\tilde{X}_1, \dots, \widehat{\tilde{X}_i}, \dots, \tilde{X}_{k+1})$$

are all constant by left invariance, so our formula becomes simply

$$(*) \quad d\omega(X_1, \dots, X_{k+1}) = \sum_{i < j} (-1)^{i+j} \omega([X_i, X_j], X_1, \dots, \widehat{X_i}, \dots, \widehat{X_j}, \dots, X_{k+1}),$$

which involves only the bracket operation in \mathfrak{g} . Now let

$$\Omega^k(\mathfrak{g}/\mathfrak{h}) = \{\omega \in \Omega^k(\mathfrak{g}) : \omega(X_1, \dots, X_k) = 0 \text{ if some } X_i \in \mathfrak{h}\}.$$

The elements of $\Omega^k(\mathfrak{g}/\mathfrak{h})$ are clearly in one-one correspondence with the left invariant forms on G which annihilate \mathfrak{h} . If $a \in H$, and $X_i \in \mathfrak{h}$, then $\text{Ad}(a)X_i \in \mathfrak{h}$, since $L_a \circ R_{a^{-1}} : H \rightarrow H$; this shows that

$$\text{Ad}(a)^* : \Omega^k(\mathfrak{g}/\mathfrak{h}) \rightarrow \Omega^k(\mathfrak{g}/\mathfrak{h}) \quad \text{for all } a \in H.$$

Let

$$\Omega^k(\mathfrak{g}/\mathfrak{h})^H = \{\omega \in \Omega^k(\mathfrak{g}/\mathfrak{h}) : \text{Ad}(a)^*\omega = \omega \text{ for all } a \in H\}.$$

The remarks in the previous paragraph show that

$$d : \Omega^k(\mathfrak{g}/\mathfrak{h})^H \rightarrow \Omega^{k+1}(\mathfrak{g}/\mathfrak{h})^H,$$

where d is now defined by (*). Moreover, Theorem 30 shows that

$$H^k(G/H) \approx \frac{\ker d : \Omega^k(\mathfrak{g}/\mathfrak{h})^H \rightarrow \Omega^{k+1}(\mathfrak{g}/\mathfrak{h})^H}{d(\Omega^{k-1}(\mathfrak{g}/\mathfrak{h})^H)}.$$

Even this description of $H^k(G/H)$ can be simplified. Notice that if $\mathfrak{h}' \subset \mathfrak{g}$ is a subspace with $\mathfrak{g} = \mathfrak{h} \oplus \mathfrak{h}'$, then the elements of $\Omega^k(\mathfrak{h}')$ are in one-one

correspondence with the elements of $\Omega^k(\mathfrak{g}/\mathfrak{h})$: given $\omega \in \Omega^k(\mathfrak{h}')$, we define the corresponding $\bar{\omega} \in \Omega^k(\mathfrak{g}/\mathfrak{h})$ by

$$\bar{\omega}(X_1, \dots, X_k) = \omega(\mathfrak{h}' \text{ component of } X_1, \dots, \mathfrak{h}' \text{ component of } X_k).$$

In particular, consider the orthogonal complement $\mathfrak{h}^\perp \subset \mathfrak{g}$ of \mathfrak{h} with respect to $\langle \cdot, \cdot \rangle_e$, where $\langle \cdot, \cdot \rangle$ is a bi-invariant metric on G . Since each L_a and R_a is an isometry of $(G, \langle \cdot, \cdot \rangle)$, the map $\text{Ad}(a): \mathfrak{g} \rightarrow \mathfrak{g}$ is an isometry with respect to $\langle \cdot, \cdot \rangle_e$. Since $\text{Ad}(a): \mathfrak{h} \rightarrow \mathfrak{h}$ for $a \in H$, we also have $\text{Ad}(a): \mathfrak{h}^\perp \rightarrow \mathfrak{h}^\perp$ for $a \in H$, and hence

$$\text{Ad}(a)^*: \Omega^k(\mathfrak{h}^\perp) \rightarrow \Omega^k(\mathfrak{h}^\perp) \quad \text{for all } a \in H.$$

If we define

$$\Omega^k(\mathfrak{h}^\perp)^H = \{\omega \in \Omega^k(\mathfrak{h}^\perp) : \text{Ad}(a)^*\omega = \omega \text{ for all } a \in H\},$$

then the elements of $\Omega^k(\mathfrak{h}^\perp)^H$ are in one-one correspondence with the elements of $\Omega^k(\mathfrak{g}/\mathfrak{h})^H$. Putting all this information together, we have finally

32. THEOREM. Let G be a compact connected Lie group, and H a closed subgroup. Then the k -dimensional de Rham cohomology $H^k(G/H)$ of G/H is naturally isomorphic to

$$H^k(G/H) \approx \frac{\ker d: \Omega^k(\mathfrak{h}^\perp)^H \rightarrow \Omega^{k+1}(\mathfrak{h}^\perp)^H}{d(\Omega^{k-1}(\mathfrak{h}^\perp)^H)},$$

where

$\mathfrak{h}^\perp \subset \mathfrak{g}$ is the orthogonal complement of \mathfrak{h}
with respect to a bi-invariant metric,

and

$$\Omega^k(\mathfrak{h}^\perp)^H = \{\omega \in \Omega^k(\mathfrak{h}^\perp) : \text{Ad}(a)^*\omega = \omega \text{ for all } a \in H\},$$

and d is defined by

$$\begin{aligned} d\omega(X_1, \dots, X_{k+1}) \\ = \sum_{i < j} (-1)^{i+j} \omega(\mathfrak{h}^\perp \text{ component of } [X_i, X_j], X_1, \dots, \widehat{X_i}, \dots, \widehat{X_j}, \dots, X_{k+1}), \\ \text{for } X_1, \dots, X_{k+1} \in \mathfrak{h}^\perp. \end{aligned}$$

The cup product in $H^*(G/H)$ corresponds to \wedge under this isomorphism.

Naturally, the simplest applications of Theorem 32 will occur when H is a large subgroup, so that \mathfrak{h}^\perp is small. As an example, we consider $G = \mathrm{SO}(n+1)$, with $H = \mathrm{SO}(n) \subset \mathrm{SO}(n+1)$, so that $G/H = \tilde{G}_n(\mathbb{R}^{n+1}) \approx \tilde{G}_1(\mathbb{R}^{n+1})$ is S^n . In this case, where the geometry is so simple, it is easiest to use Theorem 30 directly. It tells us that in computing $H^k(S^n)$, it suffices to consider k -forms ω which are invariant under the action of $\mathrm{SO}(n+1)$. In particular, at any point $p \in S^n$, the function $\omega(p) \in \Omega^k(S^n_p)$ must be invariant under any linear transformation $A: S^n_p \rightarrow S^n_p$ which is special orthogonal with respect to the usual inner product on S^n_p . Now if $0 < k < n$ and $X_1, \dots, X_k \in S^n_p$ are orthonormal, then there is an A of this sort with

$$A(X_1) = X_2, \quad A(X_2) = X_1, \quad A(X_i) = X_i, \quad i = 3, \dots, k.$$

Consequently

$$\omega(p)(X_1, \dots, X_k) = \omega(p)(X_2, X_1, \dots, X_k),$$

so $\omega(p)(X_1, \dots, X_k) = 0$. This implies that $\omega(p) = 0$. Hence $H^k(S^n) = 0$ for $0 < k < n$. For $k = n$, we can choose $\omega(p)$ to be a multiple of the volume element $\sigma(p)$ of S^n at p . Since ω must also be invariant under special orthogonal maps taking p to any other point $q \in S^n$, we see that ω must be a constant multiple of the volume element σ . We have $d\sigma = 0$ automatically, and since there are no invariant $(k-1)$ -forms, we see that $H^n(S^n) \approx \mathbb{R}$.

It will also be instructive to see what happens when we do not rely on the geometry, and use Theorem 32. The Lie algebra $\mathfrak{g} = \mathfrak{o}(n+1)$ is the set of all skew-symmetric $(n+1) \times (n+1)$ matrices, while \mathfrak{h} consists of those of the form

$$\begin{pmatrix} \boxed{M} & 0 \\ & \vdots \\ 0 & \dots & 0 \end{pmatrix}, \quad M \in \mathfrak{o}(n).$$

For the bi-invariant metric $\langle M, N \rangle = \mathrm{trace} \, MN^t = \sum_{i,j} M_{ij} N_{ij}$, the orthogonal complement \mathfrak{h}^\perp is spanned by the n matrices

$$Y_1 = \begin{pmatrix} \boxed{0} & 1 \\ & 0 \\ & \vdots \\ -1 & 0 & \dots & 0 \end{pmatrix}, \quad \dots, \quad Y_n = \begin{pmatrix} \boxed{0} & 0 \\ & \vdots \\ & 1 \\ 0 & \dots & -1 & 0 \end{pmatrix}$$

For any matrix $\tilde{A} \in H$ of the form

$$\tilde{A} = \begin{pmatrix} \boxed{A} & \begin{matrix} 0 \\ \vdots \\ 0 \end{matrix} \\ 0 & \dots & 0 & 1 \end{pmatrix}, \quad A \in \mathrm{SO}(n),$$

we compute that

$$\begin{aligned} \tilde{A}Y_i\tilde{A}^{-1} &= \begin{pmatrix} \boxed{A} & \begin{matrix} 0 \\ \vdots \\ 0 \end{matrix} \\ 0 & \dots & 0 & 1 \end{pmatrix} \begin{pmatrix} \boxed{0} & \begin{matrix} 0 \\ \vdots \\ 1 \\ \vdots \\ 0 \end{matrix} \\ 0 & \dots & -1 & \dots & 0 \end{pmatrix} \begin{pmatrix} \boxed{A^t} & \begin{matrix} 0 \\ \vdots \\ 0 \end{matrix} \\ 0 & \dots & 0 & 1 \end{pmatrix} \\ &= \begin{pmatrix} \boxed{A} & \begin{matrix} 0 \\ \vdots \\ 0 \end{matrix} \\ 0 & \dots & 0 & 1 \end{pmatrix} \begin{pmatrix} \boxed{0} & \begin{matrix} 0 \\ \vdots \\ 1 \\ \vdots \\ 0 \end{matrix} \\ -a_{1i} & \dots & -a_{ni} & 0 \end{pmatrix} \\ &= \begin{pmatrix} \boxed{0} & \begin{matrix} a_{1i} \\ \vdots \\ a_{ni} \end{matrix} \\ -a_{1i} & \dots & -a_{ni} & 0 \end{pmatrix} \\ &= \sum_{j=1}^n a_{ji} Y_j. \end{aligned}$$

So if we regard the Y_i simply as vectors in \mathbb{R}^n , then the adjoint action $\mathrm{Ad}(\tilde{A})$ on the Y_i is just the usual action of the orthogonal matrix A on the vectors Y_i . As we saw in the previous paragraph, this means that

$$\Omega^k(\mathfrak{h}^\perp)^H = \begin{cases} 0 & 0 < k < n \\ \mathbb{R} & k = n; \end{cases}$$

hence $H^k(G/H) = 0$ for $0 < k < n$, and $H^n(G/H) \approx \mathbb{R}$.

7. A SMATTERING OF CLASSICAL INVARIANT THEORY

The simple algebraic considerations used at the conclusion of the previous section won't get us very far when we replace the subgroup $H = \text{SO}(n) \subset \text{SO}(n+1)$ by a smaller subgroup. In order to analyze the more general situation in an effective way, we need to delve briefly into classical invariant theory, which was once considered the cornerstone of all mathematics, and then rapidly dwindled to a state of near extinction, although recently it has excited new interest.

As an example of the sort of question that arises in invariant theory, we consider a standard fact from algebra, to which we have already alluded on occasion. A function

$$f: \underbrace{\mathbb{R} \times \cdots \times \mathbb{R}}_m \rightarrow \mathbb{R}$$

is **symmetric** if

$$f(x_1, \dots, x_m) = f(x_{\pi(1)}, \dots, x_{\pi(m)})$$

for all permutations $\pi \in S_m$. Alternatively, if we define an operation of S_m on $\mathbb{R} \times \cdots \times \mathbb{R}$ by

$$\pi \cdot (x_1, \dots, x_m) = (x_{\pi(1)}, \dots, x_{\pi(m)}),$$

then f is symmetric if and only if

$$f(\pi \cdot x) = f(x) \quad \text{for all } x \in \mathbb{R} \times \cdots \times \mathbb{R} \quad \text{and all } \pi \in S_m.$$

As examples of symmetric functions we have the “elementary symmetric functions”

$$\begin{aligned} \sigma_1(x_1, \dots, x_m) &= \sum_{i=1}^m x_i, & \sigma_2(x_1, \dots, x_m) &= \sum_{i < j} x_i x_j \\ &\dots & & \\ \sigma_m(x_1, \dots, x_m) &= x_1 \cdots x_m; \end{aligned}$$

and for all $x, y \in \mathbb{R} \times \cdots \times \mathbb{R}$ we have $y = \pi \cdot x$ for some $\pi \in S_m$ if and only if $\sigma_i(x) = \sigma_i(y)$ for all i (compare pg. IV.65). From this we see immediately that any symmetric f can be written

$$f(x_1, \dots, x_m) = F(\sigma_1(x_1, \dots, x_m), \dots, \sigma_m(x_1, \dots, x_m))$$

for some function F . Indeed, we can define

$$F(s_1, \dots, s_m) = f(x_1, \dots, x_m) \quad \text{for any } x_1, \dots, x_m \text{ with } \sigma_i(x_1, \dots, x_m) = s_i$$

—such x_1, \dots, x_m certainly exist: we can take x_1, \dots, x_m to be the roots of the polynomial

$$x^n - s_1 x^{n-1} + \dots + (-1)^n s_n = 0.$$

On the other hand, if f is a *polynomial*, then it is by no means so evident that we can choose F to be a polynomial; the argument which establishes this fact involves a slightly delicate induction, and can be found in any standard algebra course.

Note, by the way, that the polynomials $\sigma_1, \dots, \sigma_m$ are algebraically independent, i.e., if p is any polynomial with

$$p(\sigma_1(x_1, \dots, x_m), \dots, \sigma_m(x_1, \dots, x_m)) = 0$$

for all x_1, \dots, x_m , then $p = 0$. In fact, this equation implies that

$$p(s_1, \dots, s_m) = 0$$

for all s_1, \dots, s_m , and hence that $p = 0$.

Now consider a function

$$f: \underbrace{\mathbb{R}^n \times \dots \times \mathbb{R}^n}_{m \text{ times}} \rightarrow \mathbb{R},$$

which we will often describe as a “function of m vectors in \mathbb{R}^n ”. A typical element of $\mathbb{R}^n \times \dots \times \mathbb{R}^n$ will be an m -tuple of vectors (v_1, \dots, v_m) , and each v_r is an n -tuple v_{r1}, \dots, v_{rn} . We say that a function f of m vectors in \mathbb{R}^n is **invariant under $O(n)$** if

$$f(v_1, \dots, v_m) = f(A(v_1), \dots, A(v_m))$$

for all $v_1, \dots, v_m \in \mathbb{R}^n$ and all $A \in O(n)$. Alternatively, if we define an action of $O(n)$ on $\mathbb{R}^n \times \dots \times \mathbb{R}^n$ by

$$A \cdot (v_1, \dots, v_m) = (A(v_1), \dots, A(v_m)),$$

then f is invariant under $O(n)$ if and only if

$$f(A \cdot v) = f(v) \quad \text{for all } v \in \mathbb{R}^n \times \dots \times \mathbb{R}^n \text{ and all } A \in O(n).$$

Similarly, we can consider functions invariant under any subgroup of $GL(n, \mathbb{R})$. In writing $A(v_r)$, we are considering an $n \times n$ matrix $A = (a_{ij})$ as a linear transformation $A: \mathbb{R}^n \rightarrow \mathbb{R}^n$, by the rule

$$A(e_i) = \sum_{j=1}^n a_{ji} e_j.$$

Since we are regarding $v_r = (v_{r1}, \dots, v_{rn}) = \sum_h v_{rh} e_h$ as a row vector, this means that we have

$$\begin{aligned} A(v_r) &= \sum_h v_{rh} A(e_h) = \sum_{h,j} v_{rh} a_{jh} e_j \\ &= \left(\sum_h v_{rh} a_{1h}, \dots, \sum_h v_{rh} a_{nh} \right), \end{aligned}$$

and consequently

$$A(v_r) = v_r \cdot A^t \quad \begin{array}{l} \text{[the product of the } 1 \times n \\ \text{matrix } v_r \text{ with the } n \times n \\ \text{matrix } A^t], \end{array}$$

which is slightly unpleasant, but something we can live with.

If $v, w \in \mathbb{R}^n \times \dots \times \mathbb{R}^n$ are m -tuples of vectors with $\langle v_r, v_s \rangle = \langle w_r, w_s \rangle$ for all r, s , then there is $A \in O(n)$ with $w = A \cdot v$. It follows immediately that every function f of m vectors in \mathbb{R}^n which is invariant under $O(n)$ can be written as

$$f(v_1, \dots, v_m) = F(\langle v_1, v_1 \rangle, \dots, \langle v_m, v_m \rangle)$$

for some function F . For brevity, we will also write

$$f(v_1, \dots, v_m) = F(\{\langle v_r, v_s \rangle\}),$$

and if we introduce the inner product functions

$$\iota_{rs}(v_1, \dots, v_m) = \langle v_r, v_s \rangle,$$

then we can write

$$f = F \circ (\{\iota_{rs}\}).$$

From this general, and trivial result, however, it does not follow that every *polynomial* function of m vectors in \mathbb{R}^n can be written as a *polynomial* in the ι_{rs} (a function $f: \mathbb{R}^n \times \dots \times \mathbb{R}^n \rightarrow \mathbb{R}$ is a **polynomial** function if $f(\sum a_1^i e_i, \dots, \sum a_m^i e_i)$ is a polynomial in the a_j^i). This deeper algebraic result is the content of the “first main theorem of invariant theory for $O(n)$ ”. In order to prove this result, as well as the corresponding result for $SO(n)$, we will follow the classical route, which will get us to our destination in the shortest time, although it involves some unpleasant calculations, and uses some mysterious identities.

First, some preliminaries about polynomial functions f of m vectors in \mathbb{R}^n . We say that f is **homogeneous of degree** $(\alpha_1, \dots, \alpha_m)$ if

$$f(\lambda_1 v_1, \dots, \lambda_m v_m) = \lambda_1^{\alpha_1} \dots \lambda_m^{\alpha_m} f(v_1, \dots, v_m).$$

Every polynomial function f can be written

$$(*) \quad f = \sum_{(\alpha_1, \dots, \alpha_m)} f_{\alpha_1, \dots, \alpha_m},$$

where $f_{\alpha_1, \dots, \alpha_m}$ is homogeneous of degree $(\alpha_1, \dots, \alpha_m)$. For example, we might have $f: \mathbb{R}^2 \times \mathbb{R}^2 \rightarrow \mathbb{R}$ with

$$f(x_1, x_2, y_1, y_2) = \underbrace{3x_1^2 x_2 y_1^2 + 7x_1 x_2^2 y_1 y_2}_{\text{degree } (3,2)} + \underbrace{8x_1^3}_{\text{degree } (3,0)} + \underbrace{7x_2^4}_{\text{degree } (4,0)}.$$

It is easy to see that the expression $(*)$ is unique. Moreover, if f is homogeneous of degree $(\alpha_1, \dots, \alpha_m)$, then so is

$$(v_1, \dots, v_m) \mapsto f(A \cdot v_1, \dots, A \cdot v_m)$$

for any linear transformation A . From this we easily see that if f is invariant under any group of linear transformations, then so is $f_{\alpha_1, \dots, \alpha_m}$. So we will henceforth consider only homogeneous polynomial functions.

Notice that if $f: \mathbb{R}^n \rightarrow \mathbb{R}$ satisfies $f(\lambda v) = \lambda^k f(v)$, then

$$k\lambda^{k-1} f(v) = \frac{d}{d\lambda} \lambda^k f(v) = \frac{d}{d\lambda} f(\lambda v) = \sum_{i=1}^n v_i \frac{\partial f}{\partial x_i}(\lambda v).$$

In particular, for $\lambda = 1$ we obtain *Euler's Theorem*

$$kf = \sum_{i=1}^n v_i \frac{\partial f}{\partial x_i}.$$

(In the case of a polynomial function $f: \mathbb{R}^n \rightarrow \mathbb{R}$, this result can be verified directly.) Naturally, there is an analogous result for homogeneous functions of several vectors in \mathbb{R}^n .

Now let

$$\begin{array}{c} e_{ri} = (0, \dots, e_i, \dots, 0) \in \mathbb{R}^n \times \dots \times \mathbb{R}^n, \\ \uparrow \\ r^{\text{th}} \text{ place} \end{array}$$

where 0 denotes the zero vector of \mathbb{R}^n , and e_i is the i^{th} standard basis vector of \mathbb{R}^n . The e_{ri} form the standard basis for $\mathbb{R}^n \times \dots \times \mathbb{R}^n$ when we identify it with \mathbb{R}^{nm} , so for a function

$$f: \underbrace{\mathbb{R}^n \times \dots \times \mathbb{R}^n}_{m \text{ times}} \rightarrow \mathbb{R}$$

we can consider the partial derivatives

$$\frac{\partial f}{\partial e_{ri}};$$

these partial derivatives certainly exist if f is a polynomial function. Now for $1 \leq r, s \leq m$ we can consider the function

$$(D_{sr}f)(v_1, \dots, v_m) = \sum_{i=1}^n v_{si} \frac{\partial f}{\partial e_{ri}}(v_1, \dots, v_m);$$

in terms of the dual basis $\{\phi^{ri}\}$ to the $\{e_{ri}\}$, we can write

$$D_{sr} = \sum_{i=1}^n \phi^{si} \cdot \frac{\partial}{\partial e_{ri}}.$$

For example, if $(x_1, \dots, x_n, y_1, \dots, y_n)$ denotes a typical element of $\mathbb{R}^n \times \mathbb{R}^n$, then for $f: \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}$ we have

$$D_{21}f(x_1, \dots, x_n, y_1, \dots, y_n) = \sum_{i=1}^n y_i \frac{\partial f}{\partial x_i}(x_1, \dots, x_n, y_1, \dots, y_n).$$

The operator D_{sr} is called a **polarization**. It is important for the following reason.

33. LEMMA. Suppose that

$$f(v_1, \dots, v_m) = f(A(v_1), \dots, A(v_m))$$

for all $v_1, \dots, v_m \in \mathbb{R}^n$ and some linear transformation A . Then also

$$D_{sr}f(v_1, \dots, v_m) = D_{sr}f(A(v_1), \dots, A(v_m))$$

for all $v_1, \dots, v_m \in \mathbb{R}^n$.

PROOF. If (a_{ij}) is the matrix of A , then by hypothesis we have

$$f(\dots, (v_{r1}, \dots, v_{rn}), \dots) = f(\dots, (\sum_{j=1}^n a_{1j} v_{rj}, \dots, \sum_{j=1}^n a_{nj} v_{rj}), \dots),$$

which implies that

$$\frac{\partial f}{\partial e_{ri}}(v_1, \dots, v_m) = \sum_{k=1}^n \frac{\partial f}{\partial e_{rk}}(\dots) a_{ki}.$$

Therefore

$$\begin{aligned} \sum_{i=1}^n v_{si} \frac{\partial f}{\partial e_{ri}}(v_1, \dots, v_m) &= \sum_{k=1}^n \sum_{i=1}^n a_{ki} v_{si} \frac{\partial f}{\partial e_{rk}}(\dots) \\ &= \sum_{k=1}^n A(v_s)_k \frac{\partial f}{\partial e_{rk}}(A(v_1), \dots, A(v_m)). \quad \spadesuit \end{aligned}$$

In particular, we see that polarization takes polynomial functions invariant under a group of matrices into polynomial functions with the same property. Note that if f is homogeneous of degree $(\alpha_1, \dots, \alpha_m)$, then Euler's theorem implies that $D_{rr} f = \alpha_r \cdot f$. Note also that polarizations take the inner product functions into sums of such:

$$D_{sr} l_{qp} = \delta_{rq} l_{sq} + \delta_{rp} l_{sp}.$$

Finally, consider a determinant function

$$(v_1, \dots, v_m) \mapsto \det \begin{pmatrix} v_{r_1} \\ \vdots \\ v_{r_n} \end{pmatrix},$$

which we will denote by $\det_{r_1 \dots r_n}$. We clearly have

$$\begin{aligned} D_{sr_i} \det_{r_1 \dots r_n} &= \det_{r_1 \dots r_{i-1} s r_{i+1} \dots r_n} \\ D_{sr} \det_{r_1 \dots r_n} &= 0 \quad \text{if } r \neq r_1, \dots, r_n. \end{aligned}$$

Now we want to look at the result of composing two or more polarizations. It would be nice if

$$D_{s_2 r_2} D_{s_1 r_1} f \stackrel{(?)}{=} \sum_{i_1, i_2} \phi^{s_1 i_1} \phi^{s_2 i_2} \frac{\partial^2 f}{\partial e_{r_1 i_1} \partial e_{r_2 i_2}}.$$

But this holds only when $r_2, s_2 \neq s_1$. It will be convenient, however, to denote the right side of the above equation by a symbol that looks like a composition, even in the case where r_2 or s_2 equals s_1 . So we will use the symbol Δ_{sr} for the same operator as D_{sr} , but we will define the operator $\Delta_{s_2 r_2} \Delta_{s_1 r_1}$ not as a composition, but formally by

$$\Delta_{s_2 r_2} \Delta_{s_1 r_1} = \sum_{i_1, i_2} \phi^{s_1 i_1} \phi^{s_2 i_2} \frac{\partial^2}{\partial e_{r_1 i_1} \partial e_{r_2 i_2}};$$

the operators $\Delta_{s_3 r_3} \Delta_{s_2 r_2} \Delta_{s_1 r_1}$, etc., are defined similarly. As for the actual composition $D_{s_2 r_2} D_{s_1 r_1}$ we have

$$\begin{aligned} D_{s_2 r_2} D_{s_1 r_1} f &= \sum_{i_2} \phi^{s_2 i_2} \frac{\partial}{\partial e_{r_2 i_2}} \left(\sum_{i_1} \phi^{s_1 i_1} \frac{\partial f}{\partial e_{r_1 i_1}} \right) \\ &= \sum_{i_1, i_2} \phi^{s_2 i_2} \phi^{s_1 i_1} \frac{\partial^2 f}{\partial e_{r_2 i_2} \partial e_{r_1 i_1}} + \delta_{s_1}^{r_2} \sum_{i_2} \phi^{s_2 i_2} \frac{\partial f}{\partial e_{r_1 i_2}}, \end{aligned}$$

which shows that

$$(1) \quad D_{s_2 r_2} D_{s_1 r_1} = \Delta_{s_2 r_2} \Delta_{s_1 r_1} + \delta_{s_1}^{r_2} \Delta_{s_2 r_1}.$$

Now consider the operator

$$\det \begin{pmatrix} D_{11} & D_{12} \\ D_{21} & D_{22} \end{pmatrix} \stackrel{\text{def}}{=} D_{11} D_{22} - D_{21} D_{12}.$$

From (1) we have

$$D_{11} D_{22} = \Delta_{11} \Delta_{22}, \quad D_{21} D_{12} = \Delta_{21} \Delta_{12} + \Delta_{22},$$

so

$$D_{11} D_{22} - D_{21} D_{12} + D_{22} = \Delta_{11} \Delta_{22} - \Delta_{21} \Delta_{12}.$$

We used the indices 1 and 2 for convenience, but we clearly have the same result for any distinct indices α_1, α_2 . We can write our equation as

$$(2) \quad \det \begin{pmatrix} D_{\alpha_1 \alpha_1} + 1 & D_{\alpha_1 \alpha_2} \\ D_{\alpha_2 \alpha_1} & D_{\alpha_2 \alpha_2} \end{pmatrix} = \det \begin{pmatrix} \Delta_{\alpha_1 \alpha_1} & \Delta_{\alpha_1 \alpha_2} \\ \Delta_{\alpha_2 \alpha_1} & \Delta_{\alpha_2 \alpha_2} \end{pmatrix}.$$

Remarkably enough, this equation can be generalized. First we compute that

$$\begin{aligned} D_{s_3 r_3} (\Delta_{s_2 r_2} \Delta_{s_1 r_1}) f &= \sum_{i_3} \phi^{s_3 i_3} \frac{\partial}{\partial e_{r_3 i_3}} \left(\sum_{i_1, i_2} \phi^{s_2 i_2} \phi^{s_1 i_1} \frac{\partial^2 f}{\partial e_{r_2 i_2} \partial e_{r_1 i_1}} \right) \\ &= \sum_{i_1, i_2, i_3} \phi^{s_3 i_3} \phi^{s_2 i_2} \phi^{s_1 i_1} \frac{\partial^3 f}{\partial e_{r_3 i_3} \partial e_{r_2 i_2} \partial e_{r_1 i_1}} \\ &\quad + \delta_{r_3}^{s_1} \sum_{i_2, i_3} \phi^{s_3 i_3} \phi^{s_2 i_2} \frac{\partial^2 f}{\partial e_{r_2 i_2} \partial e_{r_1 i_3}} \\ &\quad + \delta_{r_3}^{s_2} \sum_{i_1, i_3} \phi^{s_3 i_3} \phi^{s_1 i_1} \frac{\partial^2 f}{\partial e_{r_2 i_3} \partial e_{r_1 i_1}} \end{aligned}$$

(this formula works even if $s_1 = s_2$). Consequently,

$$(3) \quad D_{s_3 r_3} \circ (\Delta_{s_2 r_2} \Delta_{s_1 r_1}) = \Delta_{s_3 r_3} \Delta_{s_2 r_2} \Delta_{s_1 r_1} + \delta_{r_3}^{s_1} \Delta_{s_3 r_1} \Delta_{s_2 r_2} + \delta_{r_3}^{s_2} \Delta_{s_3 r_2} \Delta_{s_1 r_1}.$$

Now we consider the operator

$$\det \begin{pmatrix} D_{11} & \Delta_{12} & \Delta_{13} \\ D_{21} & \Delta_{22} & \Delta_{23} \\ D_{31} & \Delta_{32} & \Delta_{33} \end{pmatrix} \stackrel{\text{def}}{=} \sum_{\pi \in \mathcal{S}_3} (\text{sgn } \pi) \cdot D_{\pi(1),1} \circ (\Delta_{\pi(2),2} \Delta_{\pi(3),3}).$$

[For each term of this sum, operators in the first column of the matrix appear on the left, followed by operators from the second column, etc.] Using (3) we have

$$\begin{aligned} & \det \begin{pmatrix} D_{11} & \Delta_{12} & \Delta_{13} \\ D_{21} & \Delta_{22} & \Delta_{23} \\ D_{31} & \Delta_{32} & \Delta_{33} \end{pmatrix} \\ &= \sum_{\pi \in \mathcal{S}_3} (\text{sgn } \pi) \{ \Delta_{\pi(1),1} \Delta_{\pi(2),2} \Delta_{\pi(3),3} \\ & \quad + \delta_{\pi(3)}^1 \Delta_{\pi(1),3} \Delta_{\pi(2),2} \\ & \quad + \delta_{\pi(2)}^1 \Delta_{\pi(1),2} \Delta_{\pi(3),3} \} \\ &= \sum_{\pi \in \mathcal{S}_3} (\text{sgn } \pi) \{ \Delta_{\pi(1),1} \Delta_{\pi(2),2} \Delta_{\pi(3),3} \\ & \quad - \delta_{\pi(1)}^1 \Delta_{\pi(3),3} \Delta_{\pi(2),2} \quad \begin{array}{l} \text{[compose } \pi \text{ with the trans-} \\ \text{position interchanging} \\ \pi(1) \text{ and } \pi(3)] \end{array} \\ & \quad - \delta_{\pi(1)}^1 \Delta_{\pi(2),2} \Delta_{\pi(3),3} \} \quad \begin{array}{l} \text{[compose } \pi \text{ with the trans-} \\ \text{position interchanging} \\ \pi(1) \text{ and } \pi(2)] \end{array} \\ &= \sum_{\pi \in \mathcal{S}_3} (\text{sgn } \pi) \Delta_{\pi(1),1} \Delta_{\pi(2),2} \Delta_{\pi(3),3} \\ & \quad - 2 \sum_{\substack{\pi \in \mathcal{S}_3 \\ \text{with} \\ \pi(1)=1}} (\text{sgn } \pi) \Delta_{\pi(2),2} \Delta_{\pi(3),3} \\ &= \det \begin{pmatrix} \Delta_{11} & \Delta_{12} & \Delta_{13} \\ \Delta_{21} & \Delta_{22} & \Delta_{23} \\ \Delta_{31} & \Delta_{32} & \Delta_{33} \end{pmatrix} - 2 \det \begin{pmatrix} \Delta_{22} & \Delta_{23} \\ \Delta_{32} & \Delta_{33} \end{pmatrix}. \end{aligned}$$

We can also write this equation as

$$\det \begin{pmatrix} D_{11} + 2 & \Delta_{12} & \Delta_{13} \\ D_{21} & \Delta_{22} & \Delta_{23} \\ D_{31} & \Delta_{32} & \Delta_{33} \end{pmatrix} = \det \begin{pmatrix} \Delta_{11} & \Delta_{12} & \Delta_{13} \\ \Delta_{21} & \Delta_{22} & \Delta_{23} \\ \Delta_{31} & \Delta_{32} & \Delta_{33} \end{pmatrix}.$$

Using (2), we find that

$$\det \begin{pmatrix} D_{11} + 2 & D_{12} & D_{13} \\ D_{21} & D_{22} + 1 & D_{23} \\ D_{31} & D_{32} & D_{33} \end{pmatrix} = \det \begin{pmatrix} \Delta_{11} & \Delta_{12} & \Delta_{13} \\ \Delta_{21} & \Delta_{22} & \Delta_{23} \\ \Delta_{31} & \Delta_{32} & \Delta_{33} \end{pmatrix}.$$

Of course, the numbers 1, 2, 3 could be replaced by any three distinct integers $\alpha_1, \alpha_2, \alpha_3$ from 1 to m . The same general procedure yields, by induction, the result

$$(4) \quad \det \begin{pmatrix} D_{11} + (m-1) & D_{12} & \dots & D_{1m} \\ \vdots & D_{22} + (m-2) & & \vdots \\ \vdots & \vdots & \ddots & \vdots \\ D_{m1} & D_{m2} & \dots & D_{mm} \end{pmatrix} = \det \begin{pmatrix} \Delta_{11} & \dots & \Delta_{1m} \\ \vdots & & \vdots \\ \Delta_{m1} & \dots & \Delta_{mm} \end{pmatrix}.$$

We introduce the **Cayley Ω -process** which takes a function f of n vectors in \mathbb{R}^n to the function Ωf of n vectors defined by

$$\Omega f = \det \begin{pmatrix} \frac{\partial}{\partial e_{11}} & \dots & \frac{\partial}{\partial e_{1n}} \\ \vdots & & \vdots \\ \frac{\partial}{\partial e_{n1}} & \dots & \frac{\partial}{\partial e_{nn}} \end{pmatrix} f.$$

Notice that we could just as well write the transpose matrix here, since all partials commute. It is easily seen that

$$\Omega f(A \cdot v_1, \dots, A \cdot v_n) = (\det A) \cdot \Omega f(v_1, \dots, v_n).$$

So if f is invariant under $O(n)$ or $SO(n)$, then Ωf is invariant under $SO(n)$. Using \det for the function

$$(v_1, \dots, v_n) \mapsto \det \begin{pmatrix} v_1 \\ \vdots \\ v_n \end{pmatrix},$$

we now have

34. THEOREM (THE CAPELLI IDENTITIES). Let f be a polynomial function of m vectors in \mathbb{R}^n . Then

$$\det \begin{pmatrix} D_{11} + (m-1) & \dots & D_{1m} \\ \vdots & \ddots & \vdots \\ D_{m1} & \dots & D_{mm} \end{pmatrix} f = \begin{cases} 0 & m > n \\ \det \Omega f & m = n. \end{cases}$$

PROOF. Equation (4) shows that at (v_1, \dots, v_m) the left side of our equation has the value

$$\begin{aligned} & \sum_{\pi \in S_m} (\operatorname{sgn} \pi) \Delta_{\pi(1),1} \cdots \Delta_{\pi(m),m} f(v_1, \dots, v_m) \\ &= \sum_{\pi \in S_m} (\operatorname{sgn} \pi) \sum_{i_1, \dots, i_m=1}^n v_{\pi(1),i_1} \cdots v_{\pi(m),i_m} \frac{\partial^m f}{\partial e_{1,i_1} \cdots \partial e_{m,i_m}}(v_1, \dots, v_m) \\ &= \sum_{i_1, \dots, i_m=1}^n \left[\sum_{\pi \in S_m} (\operatorname{sgn} \pi) v_{\pi(1),i_1} \cdots v_{\pi(m),i_m} \right] \frac{\partial^m f}{\partial e_{1,i_1} \cdots \partial e_{m,i_m}}(v_1, \dots, v_m). \end{aligned}$$

If $i_\alpha = i_\beta$ for some $\alpha \neq \beta$, then the sum inside the brackets is clearly 0. This always occurs if $m > n$, so we obtain 0 for the total sum in this case. When $m = n$, the sum inside the brackets is zero unless i_1, \dots, i_n is a permutation of $1, \dots, n$, so our total sum becomes

$$\begin{aligned} & \sum_{\rho \in S_n} \left[\sum_{\pi \in S_n} (\operatorname{sgn} \pi) v_{\pi(1),\rho(1)} \cdots v_{\pi(n),\rho(n)} \right] \frac{\partial^n f}{\partial e_{1,\rho(1)} \cdots \partial e_{n,\rho(n)}}(v_1, \dots, v_n) \\ &= \sum_{\rho \in S_n} (\operatorname{sgn} \rho) \cdot \det(v_1, \dots, v_n) \cdot \frac{\partial^n f}{\partial e_{1,\rho(1)} \cdots \partial e_{n,\rho(n)}}(v_1, \dots, v_n) \\ &= \det(v_1, \dots, v_n) \cdot \Omega f(v_1, \dots, v_n). \quad \spadesuit \end{aligned}$$

In order to make use of the Capelli identities, we introduce a partial ordering $<$ on the homogeneous polynomial functions of m vectors in \mathbb{R}^n . Let f and \bar{f} be homogeneous of degrees $(\alpha_1, \dots, \alpha_m)$ and $(\bar{\alpha}_1, \dots, \bar{\alpha}_m)$, respectively, and set $d = \alpha_1 + \cdots + \alpha_m$ and $\bar{d} = \bar{\alpha}_1 + \cdots + \bar{\alpha}_m$. Then $f < \bar{f}$ if and only if: $d < \bar{d}$; or $d = \bar{d}$ and $\alpha_m < \bar{\alpha}_m$; or $d = \bar{d}$ and $\alpha_m = \bar{\alpha}_m$ and $\alpha_{m-1} < \bar{\alpha}_{m-1}$; or \dots . This can also be expressed a little differently. Among all homogeneous polynomial functions f of fixed **total degree** $d = \alpha_1 + \cdots + \alpha_m$, we can consider $(\alpha_m, \alpha_{m-1}, \dots, \alpha_1)$ as the digits of a number to the base $d + 1$. We define the **rank** of f to be this number,

$$\operatorname{rank} f = \alpha_1 + \alpha_2(d + 1) + \alpha_3(d + 1)^2 + \cdots + \alpha_m(d + 1)^{m-1}.$$

If f and g both have total degree d , then $f < g$ if and only if $\operatorname{rank} f < \operatorname{rank} g$.

Now consider the effect on f of the operator on the left side of the Capelli identities. The main term

$$(D_{11} + m - 1) \cdots D_{mm} f$$

is (by Euler's theorem) just

$$(\alpha_1 + m - 1) \cdots a_m f = (\text{constant}) \cdot f,$$

and this constant is 0 only if f does not depend on v_m . All other terms will involve certain diagonal terms, which are all just multiplications by constants, and a term

$$D_{s_1 r_1} \cdots D_{s_\mu r_\mu} f \quad \text{where} \quad \begin{cases} r_1 < \cdots < r_\mu \\ s_i \neq r_i \\ s_1, \dots, s_\mu \text{ is a permutation} \\ \text{of } r_1, \dots, r_\mu. \end{cases}$$

In particular, $s_\mu < r_\mu$. But $D_{s_\mu r_\mu} f$ is homogeneous of degree

$$(\alpha_1, \dots, \alpha_{s_\mu} + 1, \dots, \alpha_{r_\mu} - 1, \dots, \alpha_m),$$

which means that $D_{s_\mu r_\mu} f < f$. Thus

$$D_{s_1 r_1} \cdots D_{s_\mu r_\mu} f = D_{s_1 r_1} \cdots f^* = \mathcal{P} f^*,$$

where $f^* < f$, and \mathcal{P} is a composition of polarizations; since f^* is itself a polarization of f , it is invariant under $O(n)$ or $SO(n)$ if f is. So the Cappeli identities show that

$$(A) \quad (\text{constant}) \cdot f = \begin{cases} \text{a sum of terms } \mathcal{P} f^* & m > n \\ \text{a sum of terms } \mathcal{P} f^* + \det \cdot \Omega f & m = n \end{cases}$$

where $f^* < f$ is invariant under $O(n)$ or $SO(n)$ if f is, \mathcal{P} is a composition of polarizations, and the constant is 0 only if f does not depend on v_m .

We are now ready to prove

35. THEOREM. For all m and n we have

O_n^m : Every polynomial function f of m vectors in \mathbb{R}^n which is invariant under $O(n)$ can be written as a polynomial in the inner product functions ι_{rs} .

SO_n^m : Every polynomial function f of m vectors in \mathbb{R}^n which is invariant under $SO(n)$ can be written as a polynomial in the functions ι_{rs} and the determinant functions $\det_{r_1 \dots r_n}$.

PROOF. Notice that a function of m vectors can always be thought of as a function of a larger number of vectors; so $O_n^m \implies O_n^{m'}$ and $SO_n^m \implies SO_n^{m'}$ automatically for $m' < m$. Note also that the determinants in SO_n^m are zero unless $m \geq n$.

The proof of O_n^m and SO_n^m proceeds in two parts.

36. LEMMA. If O_n^n [respectively SO_n^n] holds, then O_n^m [respectively SO_n^m] holds for all $m > n$.

PROOF. The proof for SO will be almost exactly the same as for O, so we give only the latter. Actually, we give the proof only for O_n^{n+1} , as it will then be clear how to proceed by induction. We consider invariant homogeneous polynomial functions f of $n+1$ vectors in \mathbb{R}^n , of fixed total degree d . We will prove that they can be represented in the desired form by complete induction on their rank. If $\text{rank } f < (d+1)^n$, so that the degree α_n of f in v_{n+1} is 0, then f does not involve v_{n+1} , so the result follows from the hypothesis that O_n^n holds. Let $r_0 \geq (d+1)^n$. Assuming that all f of total degree d and rank $< r_0$ can be expressed in the desired form, we will show that all f of total degree d and rank r_0 can also be so expressed. The constant in equation (A) is $\neq 0$ for our f , so f is the sum of terms $\mathcal{P}f^*$, where $f^* < f$ is invariant under $O(n)$ and \mathcal{P} is a composition of polarizations. Since f^* is a single polarization applied to f , the total degree of f^* equals the total degree of f . Since $f^* < f$, the inductive assumption says that each f^* can be written

$$f^* = F^* \circ (\{t_{rs}\})$$

for some polynomial F^* . This implies that

$$\mathcal{P}f^* = \mathcal{F}^* \circ (\{\mathcal{P}t_{rs}\})$$

for some polynomial \mathcal{F}^* . Since each $\mathcal{P}t_{rs}$ is a sum of t_{rs} 's, it follows that each $\mathcal{P}f^*$ is a polynomial in the t_{rs} , and thus f is. **Q.E.D.**

We still have to show that O_n^n and SO_n^n hold. In the case of SO_n^n there is a single determinant $\det(v_{ri})$ involved. If $A = (v_{ri})$, then

$$(A \cdot A^t)_{rs} = \sum_k v_{rk} v_{sk} = \langle v_r, v_s \rangle.$$

Hence

$$[\det(v_{ri})]^2 = \det A \cdot A^t = \det(\langle v_r, v_s \rangle)$$

is a polynomial in the t_{rs} . Thus we need only linear terms in \det .

37. LEMMA. O_n^n holds for all n . Moreover, SO_n^n holds in the strengthened form

SO_n^n : Every polynomial function of n vectors in \mathbb{R}^n which is invariant under $SO(n)$ can be written as $g + (\det) \cdot h$, where g and h are polynomials in the inner product functions t_{rs} .

PROOF. We use induction on n . Consider first a polynomial function $f: \mathbb{R} \rightarrow \mathbb{R}$. If f is invariant under $O(1)$, then $f(x) = f(-x)$. So $f(x)$ involves only even powers of x . Hence $f(x) = F(x^2) = F(\langle x, x \rangle)$ for some polynomial F . Moreover, *any* polynomial function $f: \mathbb{R} \rightarrow \mathbb{R}$ can be written

$$f(x) = g(x) + xh(x) = g(x) + (\det x) \cdot h(x),$$

where g and h involve only even powers.

To carry out the induction step,

$$(*) \quad \{O_{n-1}^{n-1} \text{ and } SO_{n-1}^{n-1}\} \implies \{O_n^n \text{ and } SO_n^n\},$$

we first show that

$$O_{n-1}^{n-1} \implies SO_n^{n-1} \quad (\implies O_n^{n-1}, \text{ since no determinants are involved}).$$

So consider a polynomial function f of $n-1$ vectors in \mathbb{R}^n . Define a polynomial function \bar{f} of $n-1$ vectors in \mathbb{R}^{n-1} by

$$\bar{f}(w_1, \dots, w_{n-1}) = f(\bar{w}_1, \dots, \bar{w}_{n-1}),$$

where

$$\bar{w}_r = (w_{r1}, \dots, w_{r,n-1}, 0).$$

If f is invariant under $SO(n)$, then \bar{f} is actually invariant under $O(n-1)$. So by hypothesis, there is a polynomial \bar{F} with

$$\bar{f}(w_1, \dots, w_{n-1}) = \bar{F}(\{\langle w_r, w_s \rangle\}).$$

Now given $v_1, \dots, v_{n-1} \in \mathbb{R}^n$, choose $A \in SO(n)$ so that all $A \cdot v_r$ lie in $\mathbb{R}^{n-1} \times \{0\}$, and hence $A \cdot v_r = \bar{w}_r$ for some $w_r \in \mathbb{R}^{n-1}$. Then

$$\begin{aligned} f(v_1, \dots, v_{n-1}) &= f(A \cdot v_1, \dots, A \cdot v_{n-1}) = f(\bar{w}_1, \dots, \bar{w}_{n-1}) \\ &= \bar{f}(w_1, \dots, w_n) = \bar{F}(\{\langle w_r, w_s \rangle\}) \\ &= \bar{F}(\{\langle v_r, v_s \rangle\}). \end{aligned}$$

This completes the proof that $O_{n-1}^{n-1} \implies SO_n^{n-1}$.

Now for the proof of (*). This proof will also be by induction, using the same general scheme as in the previous lemma, but there will be a slight complication, for we will actually be using a double induction, first on the total degree of f , and then within each total degree on the rank. In addition, the statements O_n^n and SO_n^n will have to be proved jointly in the induction. Thus, for a fixed total

degree and rank, we will show that all f of this degree and rank which are invariant under $O(n)$ have the desired form, and also that all f of this degree and rank which are invariant under $SO(n)$ have the desired form, assuming that the same two statements hold for all f of lower degree, or of the same degree and lower rank. There is certainly no problem beginning the induction with degree 0; moreover, within any particular degree, the polynomials of sufficiently low rank will not involve v_n , so we will be back to the cases SO_n^{n-1} and O_n^{n-1} which we have already proved.

Now consider a particular invariant f . We use equation (A), in the case $m = n$, to see that f is a sum of terms $\mathcal{P}f^*$ plus a constant times $\det \cdot \Omega f$. The sum of the terms $\mathcal{P}f^*$ can be written as $F \circ (\{\iota_{rs}\})$, as before, and we just have to worry about $\det \cdot \Omega f$. First suppose that f is invariant under $O(n)$. Then $\Omega f \prec f$ is invariant under $SO(n)$, so by the induction hypothesis we can write

$$\Omega f = g + (\det) \cdot h,$$

where $g, h \prec f$ are invariant under $O(n)$, and thus by the induction hypothesis expressible as polynomials in the ι_{rs} . So we have

$$f = F \circ (\{\iota_{rs}\}) + (\text{constant}) \cdot \det \cdot [G \circ (\{\iota_{rs}\}) + \det \cdot H \circ (\{\iota_{rs}\})].$$

Since f, ι_{rs} , and \det^2 are invariant under $O(n)$, the term $\det \cdot G \circ (\{\iota_{rs}\})$ must also be invariant under $O(n)$, which is possible only if $G = 0$. Thus f is a polynomial in the ι_{rs} .

If f is assumed invariant under $SO(n)$, then everything remains the same, except that G need not be zero. ♦

8. AN EASIER INVARIANCE PROBLEM

For an $n \times n$ matrix M , we define $f_1(M), \dots, f_n(M)$ by

$$\det(I + \lambda M) = 1 + \lambda f_1(M) + \dots + \lambda^n f_n(M).$$

It will also be convenient to set $f_0(M) = 1$. Then the f_i are polynomial functions of the entries of M which are invariant under the adjoint action of $GL(n, \mathbb{R})$,

$$f_i(\text{Ad}(A)M) = f_i(AMA^{-1}) = f_i(M) \quad \text{for } A \in GL(n, \mathbb{R}).$$

If M has eigenvalues $\lambda_1, \dots, \lambda_n$, and σ_i denotes the i^{th} elementary symmetric polynomial, then*

$$f_i(M) = \sigma_i(\lambda_1, \dots, \lambda_n).$$

According to Problem I.7-15, every polynomial function on the $n \times n$ matrices $\mathfrak{gl}(n, \mathbb{R})$ which is invariant under the adjoint action of $\text{GL}(n, \mathbb{R})$ is a polynomial in the f_i (notice that we are now considering functions of a *single matrix*, rather than functions of *many vectors*). Now we want to find out which polynomial functions on $\mathfrak{o}(n)$ are invariant under the adjoint action of $\text{O}(n)$, or of $\text{SO}(n)$. The line of argument will be essentially that used in Problem I.7-15, except that in some ways it will be even easier, since we have an especially simple “canonical form” for elements of $\mathfrak{o}(n)$, which greatly strengthens Corollary 11:

38. PROPOSITION. For every $A \in \mathfrak{o}(n)$ there is a matrix $B \in \text{O}(n)$ such that BAB^{-1} equals either

$$\begin{pmatrix} 0 & \lambda_1 & & & 0 \\ -\lambda_1 & 0 & & & \\ & & \ddots & & \\ 0 & & & 0 & \lambda_m \\ & & & -\lambda_m & 0 \end{pmatrix} \quad \text{or} \quad \begin{pmatrix} 0 & \lambda_1 & & & 0 \\ -\lambda_1 & 0 & & & \\ & & \ddots & & \\ 0 & & & 0 & \lambda_m \\ & & & -\lambda_m & 0 \\ & & & & & 0 \end{pmatrix}$$

(some of the λ 's may also be 0).

PROOF. If $T: \mathbb{R}^n \rightarrow \mathbb{R}^n$ is the linear transformation determined by A , then the skew-symmetry of A means that

$$(1) \quad \langle Tv, w \rangle = -\langle v, Tw \rangle \quad \text{for } v, w \in \mathbb{R}^n.$$

[Conversely, if this relation holds for $T: (V, \langle \cdot, \cdot \rangle) \rightarrow (V, \langle \cdot, \cdot \rangle)$, then the matrix of T with respect to an orthonormal basis is skew-symmetric, and we have

$$(2) \quad \det T = 0 \quad \text{if } \dim V \text{ is odd}$$

as a particular consequence.] Equation (1) implies that $(\text{image } T)^\perp = \ker T$. Consequently, T must be one-one on $\text{image } T$. Therefore $\text{rank } T^2 = \text{rank } T$.

*The λ_i are the roots of the characteristic polynomial $\chi(\lambda) = \det(\lambda I - M)$. Recall that the $\sigma_i = \sigma_i(\lambda_1, \dots, \lambda_n)$ satisfy $\lambda^n - \sigma_1 \lambda^{n-1} + \dots = \prod_i (\lambda - \lambda_i) = \chi(\lambda)$. So $\lambda^n + \sigma_1 \lambda^{n-1} + \dots = (-1)^n \chi(-\lambda) = (-1)^n \det(-\lambda I - M) = \det(\lambda I + M)$. Hence, $\det(I + \lambda M) = \lambda^n \det(I/\lambda + M) = \lambda^n [(1/\lambda)^n + \sigma_1 (1/\lambda)^{n-1} + \dots] = 1 + \sigma_1 \lambda + \dots$.

Moreover, this rank is even, by Corollary 11. [Alternate proof: The map $T|(\text{image } T): \text{image } T \rightarrow \text{image } T$ is one-one, so its determinant must be non-zero. Applying (2), we see that $\dim \text{image } T$ is even.]

Now A^2 is symmetric, so there is an orthonormal basis v_1, \dots, v_n of eigenvectors of T^2 , with eigenvalues μ_1, \dots, μ_n . Note that

$$\mu_j = \langle v_j, T^2 v_j \rangle = -\langle T v_j, T v_j \rangle \leq 0.$$

By renumbering, we can assume that $\mu_1, \dots, \mu_{2m} < 0$, and that the remaining μ 's equal 0. Define a new orthonormal basis w_1, \dots, w_n by

$$\begin{aligned} w_1 &= v_1, & w_2 &= \frac{1}{\sqrt{-\lambda_1}} T(v_1) \\ &\vdots & & \\ w_{2m-1} &= v_m, & w_{2m} &= \frac{1}{\sqrt{-\lambda_m}} T(v_m) \\ w_j &= v_j & j &> 2m. \end{aligned}$$

The matrix of T has the desired form with respect to the basis w_1, \dots, w_n . ♦

Notice that for $M \in \mathfrak{o}(n)$ we have

$$(I + \lambda M)^t = I - \lambda M \implies \det(I + \lambda M) = \det(I - \lambda M),$$

so

$$1 + \lambda f_1(M) + \dots + \lambda^n f_n(M) = 1 - \lambda f_1(M) + \dots + (-1)^n \lambda^n f_n(M),$$

and hence $f_i(M) = 0$ for odd i . We will also need to use the following formula, whose verification is left to the reader:

$$\sigma_{2k}(\lambda_1, -\lambda_1, \lambda_2, -\lambda_2, \dots, \lambda_m, -\lambda_m) = \sigma_k(-\lambda_1^2, \dots, -\lambda_m^2).$$

39. THEOREM. Let $n = 2m$ or $n = 2m + 1$. Then every polynomial function f on $\mathfrak{o}(n)$ which is invariant under the adjoint action of $O(n)$ is a polynomial in f_2, \dots, f_{2m} .

PROOF. For $\lambda_1, \dots, \lambda_m \in \mathbb{R}$, let $[\lambda_1, \dots, \lambda_m]$ be

$$\begin{pmatrix} 0 & \lambda_1 & & 0 \\ -\lambda_1 & 0 & & \\ & & \ddots & \\ 0 & & & 0 & \lambda_m \\ & & & -\lambda_m & 0 \end{pmatrix} \text{ or } \begin{pmatrix} 0 & \lambda_1 & & 0 \\ -\lambda_1 & 0 & & \\ & & \ddots & \\ 0 & & & 0 & \lambda_m \\ & & & -\lambda_m & 0 \\ & & & & 0 \end{pmatrix},$$

depending on whether $n = 2m$ or $n = 2m + 1$. Notice that the eigenvalues of $[\lambda_1, \dots, \lambda_m]$ are $i\lambda_1, -i\lambda_1, \dots, i\lambda_m, -i\lambda_m$ [and 0, if $n = 2m + 1$], so

$$\begin{aligned} f_{2k}([\lambda_1, \dots, \lambda_m]) &= \sigma_{2k}(i\lambda_1, -i\lambda_1, \dots, i\lambda_m, -i\lambda_m) \\ &= \sigma_k(\lambda_1^2, \dots, \lambda_m^2). \end{aligned}$$

Define

$$g(\lambda_1, \dots, \lambda_m) = f([\lambda_1, \dots, \lambda_m]).$$

Then g is a polynomial function of $\lambda_1, \dots, \lambda_m$. Notice that for the matrix

$$A = \begin{pmatrix} 0 & 1 & 0 & & 0 \\ & 0 & 1 & & \\ 1 & 0 & & & \\ 0 & 1 & 0 & & \\ & & & 1 & \\ 0 & & & & \ddots & \\ & & & & & 1 \end{pmatrix} \in O(n)$$

we have

$$A \cdot [\lambda_1, \dots, \lambda_m] \cdot A^{-1} = [\lambda_2, \lambda_1, \dots, \lambda_m].$$

Similarly, we can interchange any two λ 's by some $A \in O(n)$. Thus g is symmetric in the λ 's. Notice, moreover, that for the matrix

$$B = \begin{pmatrix} 0 & 1 & & 0 \\ 1 & 0 & & \\ & & 1 & \\ 0 & & & \ddots & \\ & & & & 1 \end{pmatrix} \in O(n)$$

we have

$$B \cdot [\lambda_1, \dots, \lambda_m] B^{-1} = [-\lambda_1, \lambda_2, \dots, \lambda_m].$$

Thus

$$g(\lambda_1, \dots, \lambda_m) = g(-\lambda_1, \lambda_2, \dots, \lambda_m).$$

This shows that the polynomial g does not have any terms involving λ_1 to an odd power. The same result clearly holds for all λ 's, so we can write

$$g(\lambda_1, \dots, \lambda_m) = h(\lambda_1^2, \dots, \lambda_m^2)$$

for some polynomial h . Clearly h is symmetric in its arguments, so there is a polynomial p with

$$g(\lambda_1, \dots, \lambda_m) = p(\sigma_1(\lambda_1^2, \dots, \lambda_m^2), \dots, \sigma_m(\lambda_1^2, \dots, \lambda_m^2)).$$

Thus we have

$$f([\lambda_1, \dots, \lambda_m]) = p(f_2([\lambda_1, \dots, \lambda_m]), \dots, f_{2m}([\lambda_1, \dots, \lambda_m])).$$

Now for any $M \in \mathfrak{o}(n)$ there is, by Proposition 38, some $A \in O(n)$ such that $A^{-1}MA = [\lambda_1, \dots, \lambda_m]$ for some $\lambda_1, \dots, \lambda_m$. Since f, f_2, \dots, f_{2m} are invariant under the adjoint action of $O(n)$, the above equation yields

$$f(M) = p(f_2(M), \dots, f_{2m}(M)). \quad \blacklozenge$$

Note that the polynomial functions f_2, \dots, f_{2m} are algebraically independent on $\mathfrak{o}(n)$ —if

$$p(f_2(M), \dots, f_{2m}(M)) = 0$$

for all $M \in \mathfrak{o}(n)$, then $p = 0$. Indeed, this equation implies that

$$p(\sigma_1(\lambda_1^2, \dots, \lambda_m^2), \dots, \sigma_m(\lambda_1^2, \dots, \lambda_m^2)) = 0$$

for all $\lambda_1, \dots, \lambda_m$, and thus that the polynomial

$$p(\sigma_1(x_1, \dots, x_m), \dots, \sigma_m(x_1, \dots, x_m))$$

is zero whenever x_1, \dots, x_m take on positive values; but this implies that this polynomial in x_1, \dots, x_m is identically zero, and hence that $p = 0$, as we remarked on page 318.

With slight modifications of our previous argument we obtain

40. THEOREM. (1) If $n = 2m + 1$, then every polynomial function f on $\mathfrak{o}(n)$ which is invariant under the adjoint action of $\mathrm{SO}(n)$ is a polynomial in f_2, \dots, f_{2m} .

(2) If $n = 2m$, then every polynomial function f on $\mathfrak{o}(n)$ which is invariant under the adjoint action of $\mathrm{SO}(n)$ is a polynomial in f_2, \dots, f_{2m-2} and the Pfaffian Pf .

PROOF. (1) Notice that the matrix A in the proof of Theorem 39 is actually in $\mathrm{SO}(n)$. If n is odd, then $[\lambda_1, \dots, \lambda_m]$ has a zero in the $(n, n)^{\mathrm{th}}$ place, so for the matrix B in the proof of Theorem 39 we can just as well replace the 1 in the $(n, n)^{\mathrm{th}}$ place by -1 ; this new B is in $\mathrm{SO}(n)$. Now the proof of Theorem 39 goes through as before.

(2) The matrix A is still in $\mathrm{SO}(n)$. We cannot arrange for B to be in $\mathrm{SO}(n)$, but for the matrix

$$C = \begin{pmatrix} 0 & 1 & & & & \\ 1 & 0 & & & & \\ & & 0 & 1 & & \\ & & 1 & 0 & & \\ & & & & 1 & \\ & & & & & \ddots \\ & & & & & & 1 \end{pmatrix} \in \mathrm{SO}(n),$$

we have

$$C \cdot [\lambda_1, \dots, \lambda_m] C^{-1} = [-\lambda_1, -\lambda_2, \lambda_3, \dots, \lambda_m].$$

Similarly, we can send any pair of λ 's to their negatives. So the symmetric function g in the proof of Theorem 39 has the property that each monomial appearing in it is either of even degree in all λ 's or else of odd degree in all λ 's. So g can be written

$$g(\lambda_1, \dots, \lambda_m) = h_1(\lambda_1^2, \dots, \lambda_m^2) + (\lambda_1 \cdots \lambda_m) h_2(\lambda_1^2, \dots, \lambda_m^2).$$

Since g is symmetric, the term $h_1(\lambda_1^2, \dots, \lambda_m^2)$ [= the sum of the monomials of g which are of even degree in all λ 's] must be symmetric in $\lambda_1, \dots, \lambda_m$. So h_1 is symmetric in its arguments. Thus h_2 is also symmetric in its arguments. So we can write

$$\begin{aligned} g(\lambda_1, \dots, \lambda_m) &= p_1(\sigma_1(\lambda_1^2, \dots, \lambda_m^2), \dots, \sigma_m(\lambda_1^2, \dots, \lambda_m^2)) \\ &\quad + (\lambda_1 \cdots \lambda_m) \cdot p_2(\sigma_1(\lambda_1^2, \dots, \lambda_m^2), \dots, \sigma_m(\lambda_1^2, \dots, \lambda_m^2)). \end{aligned}$$

Thus we have

$$f([\lambda_1, \dots, \lambda_m]) = p_1(f_2([\lambda_1, \dots, \lambda_m], \dots, f_{2m}([\lambda_1, \dots, \lambda_m])) \\ + \text{Pf}([\lambda_1, \dots, \lambda_m]) \cdot p_2(f_2([\lambda_1, \dots, \lambda_m]), \dots, f_{2m}([\lambda_1, \dots, \lambda_m]))).$$

It follows, as before, that

$$f(M) = p_1(f_2(M), \dots, f_{2m}(M)) \\ + \text{Pf}(M) \cdot p_2(f_2(M), \dots, f_{2m}(M))$$

for all $M \in \mathfrak{o}(n)$. We can dispense with f_{2m} , since

$$f_{2m}(M) = \det M = \{\text{Pf}(M)\}^2. \spadesuit$$

We have already observed that the polynomials f_2, \dots, f_{2m} are algebraically independent on $\mathfrak{o}(n)$. For $n = 2m$, the polynomials $f_2, \dots, f_{2m-2}, \text{Pf}$ are algebraically independent on $\mathfrak{o}(n)$. For suppose that

$$p(f_2(M), \dots, f_{2m-2}(M), \text{Pf}(M)) = 0 \quad \text{for all } M \in \mathfrak{o}(n).$$

Then for all $\lambda_1, \dots, \lambda_m$ we have

$$0 = p(\sigma_1(\lambda_1^2, \dots, \lambda_m^2), \dots, \sigma_{m-1}(\lambda_1^2, \dots, \lambda_m^2), \lambda_1 \cdots \lambda_m) \\ = p_1(\sigma_1(\lambda_1^2, \dots, \lambda_m^2), \dots, \sigma_{m-1}(\lambda_1^2, \dots, \lambda_m^2), \sigma_m(\lambda_1^2, \dots, \lambda_m^2)) + \\ (\lambda_1 \cdots \lambda_m) p_2(\sigma_1(\lambda_1^2, \dots, \lambda_m^2), \dots, \sigma_{m-1}(\lambda_1^2, \dots, \lambda_m^2), \sigma_m(\lambda_1^2, \dots, \lambda_m^2)),$$

for certain polynomials p_1 and p_2 . This polynomial in $\lambda_1, \dots, \lambda_m$ can be zero only if the two summands, representing the terms with all λ 's of even degree and the terms with all λ 's of odd degree, respectively, are each zero. Then as before we conclude that $p_1 = p_2 = 0$.

There is one further simple property of the functions f_k . In Corollary 13 we gave a formula for $\text{Pf}(A \oplus B)$, where

$$A \oplus B = \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix}.$$

It is easy to find a formula for $f_k(A \oplus B)$, for all $A \in \mathfrak{gl}(r, \mathbb{R})$ and $B \in \mathfrak{gl}(s, \mathbb{R})$. For we have

$$\det(I_{r+s} + \lambda(A \oplus B)) \\ = \det((I_r + \lambda A) \oplus (I_s + \lambda B)) \\ = \det(I_r + \lambda A) \cdot \det(I_s + \lambda B) \\ = (1 + \lambda f_1(A) + \cdots + \lambda^r f_r(A)) \cdot (1 + \lambda f_1(B) + \cdots + \lambda^s f_s(B)).$$

So

$$f_k(A \oplus B) = \text{coefficient of } \lambda^k = \sum_{l=0}^k f_l(A) \cdot f_{k-l}(B).$$

When A and B are skew-symmetric, we have

$$f_{2k}(A \oplus B) = \sum_{l=1}^k f_{2l}(A) \cdot f_{2k-2l}(B).$$

9. THE COHOMOLOGY OF THE ORIENTED GRASSMANNIANS

We are now ready to compute part of the cohomology of

$$\tilde{G}_n(\mathbb{R}^N) = \text{SO}(N)/\text{SO}(n) \times \text{SO}(N-n) = \text{SO}(N)/H.$$

The Lie algebra $\mathfrak{o}(N)$ has as a basis the matrices

$$X_{\alpha}^{\beta} = \begin{matrix} & \alpha & \beta \\ \alpha & & \\ \beta & \begin{pmatrix} & 1 \\ -1 & \end{pmatrix} \end{matrix} \quad 1 \leq \alpha < \beta \leq N$$

which have non-zero entries only in the (α, β) and (β, α) positions. [We adopt the convention that the indices α, β range from 1 to N , while the indices i, j run from 1 to n , and r, s range from $n+1$ to N .] Let $\{\phi_{\alpha}^{\beta}\}$ be the dual basis to the $\{X_{\alpha}^{\beta}\}$. The Lie algebra \mathfrak{h} consists of matrices

$$\begin{pmatrix} L_1 & 0 \\ 0 & L_2 \end{pmatrix}, \quad \begin{matrix} L_1 \in \mathfrak{o}(n) \\ L_2 \in \mathfrak{o}(N-n). \end{matrix}$$

The orthogonal complement \mathfrak{h}^{\perp} , with respect to the bi-invariant metric on page 308, consists of all matrices

$$\begin{pmatrix} 0 & P \\ -P^t & 0 \end{pmatrix}, \quad P \text{ an } n \times (N-n) \text{ matrix,}$$

and has as basis the X_i^r for $1 \leq i \leq n$ and $n+1 \leq r \leq N$; so the corresponding ϕ_i^r are a basis for $(\mathfrak{h}^{\perp})^*$ [more precisely, the restrictions of the ϕ_i^r to \mathfrak{h}^{\perp} are a basis].

The adjoint action of $\mathrm{SO}(n) \times \mathrm{SO}(N - n)$ on \mathfrak{h}^\perp is easily computed to be

$$\begin{aligned} \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix} \begin{pmatrix} 0 & P \\ -P^t & 0 \end{pmatrix} \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix}^{-1} &= \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix} \begin{pmatrix} 0 & P \\ -P^t & 0 \end{pmatrix} \begin{pmatrix} A^t & 0 \\ 0 & B^t \end{pmatrix} \\ &= \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix} \begin{pmatrix} 0 & PB^t \\ -P^t A^t & 0 \end{pmatrix} \\ &= \begin{pmatrix} 0 & APB^t \\ -BP^t A^t & 0 \end{pmatrix}. \end{aligned}$$

We want to know which elements of $\Omega^k(\mathfrak{h}^\perp)$ are invariant under the induced adjoint action of $\mathrm{SO}(n) \times \mathrm{SO}(N - n)$. We will split this question up into two parts, by considering invariance under the adjoint action of the two subgroups

$$\begin{aligned} \mathrm{SO}(n) \times \{I\} &= \left\{ \begin{pmatrix} A & 0 \\ 0 & I \end{pmatrix} : A \in \mathrm{SO}(n) \right\} \\ \{I\} \times \mathrm{SO}(N - n) &= \left\{ \begin{pmatrix} I & 0 \\ 0 & B \end{pmatrix} : B \in \mathrm{SO}(N - n) \right\}. \end{aligned}$$

We consider first the adjoint action of $\{I\} \times \mathrm{SO}(N - n)$, given by

$$\begin{pmatrix} I & 0 \\ 0 & B \end{pmatrix} \begin{pmatrix} 0 & P \\ -P^t & 0 \end{pmatrix} \begin{pmatrix} I & 0 \\ 0 & B \end{pmatrix}^{-1} = \begin{pmatrix} 0 & PB^t \\ -BP^t & 0 \end{pmatrix}.$$

If we regard \mathfrak{h}^\perp as the n -fold product $\mathbb{R}^{N-n} \times \cdots \times \mathbb{R}^{N-n}$ by identifying $\begin{pmatrix} 0 & P \\ -P^t & 0 \end{pmatrix} \in \mathfrak{h}^\perp$ with the n -tuple of the rows of P , then this action is the usual action of $\mathrm{SO}(N - n)$ on each factor. Since a form $\eta \in \Omega^k(\mathfrak{h}^\perp)$ can be regarded as a polynomial function on the nk -fold product $\mathbb{R}^{N-n} \times \cdots \times \mathbb{R}^{N-n}$, Theorem 35 shows that η is invariant under the adjoint action of $\{I\} \times \mathrm{SO}(N - n)$ if and only if it is a polynomial in the inner products and determinants of the vectors involved. We have to figure out just what this means when η is a k -form, and express η in terms of the forms ϕ_i^r . *From now on we assume that $k < N - n$.*

Consider first the case where η is a 1-form, and thus a function $\eta: \mathfrak{h}^\perp \rightarrow \mathbb{R}$. If η is invariant under $\{I\} \times \mathrm{SO}(N - n)$, and $M = \begin{pmatrix} 0 & P \\ -P^t & 0 \end{pmatrix}$, then $\eta(M)$ can be written as a polynomial in the inner products of rows of P and in the $(N - n) \times (N - n)$ subdeterminants of P . Thus $\eta(M)$ is a polynomial in

$$\sum_{r=n+1}^N \phi_{i_1}^r(M) \cdot \phi_{i_2}^r(M) \quad 1 \leq i_1, i_2 \leq n$$

and

the determinants of the matrices formed
by picking $(N - n)$ rows of P .

Multiplying M by $\alpha \in \mathbb{R}$ multiplies the first terms by α^2 and the determinants by α^{N-n} . So $\eta(M)$ cannot be linear in M unless it is zero. Thus $\Omega^1(\mathfrak{h}^\perp)^H = 0$.

Now consider a 2-form $\eta \in \Omega^2(\mathfrak{h}^\perp)$. If η is invariant under $\{I\} \times \text{SO}(N - n)$, then $\eta(M_1, M_2)$ can be written as a polynomial in

$$\sum_r \phi_{i_1}^r(M_1) \cdot \phi_{i_2}^r(M_1), \quad \sum_r \phi_{i_1}^r(M_2) \cdot \phi_{i_2}^r(M_2), \quad \sum_r \phi_{i_1}^r(M_1) \cdot \phi_{i_2}^r(M_2)$$

and

the determinants of the matrices formed by picking n_1 rows
of P_1 and n_2 rows of P_2 , with $n_1 + n_2 = (N - n)$.

Multiplying M_1 [or M_2] by α multiplies these determinants by α^{n_1} [or α^{n_2}]. But either $n_1 > 1$ or $n_2 > 1$, since we are assuming that $2 = k < N - n$. Consequently, since η is multilinear, the determinants cannot be involved. Moreover, of the remaining terms, only those of the third kind can be involved. So

$$\eta = \text{a linear combination of the } \sum_r \phi_{i_1}^r \otimes \phi_{i_2}^r.$$

Since η is a 2-form, we have

$$\eta = \text{Alt } \eta = \text{a linear combination of the } \sum_r \phi_{i_1}^r \wedge \phi_{i_2}^r.$$

Thus $\Omega^2(\mathfrak{h}^\perp)^H$ can contain only linear combinations of the 2-forms

$$\zeta_{i_1 i_2} = \sum_r \phi_{i_1}^r \wedge \phi_{i_2}^r \quad 1 \leq i_1 < i_2 \leq n.$$

For a 3-form $\eta \in \Omega^3(\mathfrak{h}^\perp)$ to be invariant under $\{I\} \times \text{SO}(N - n)$, it must be possible to write $\eta(M_1, M_2, M_3)$ as a polynomial in

$$\sum_r \phi_{i_1}^r(M_{j_1}) \cdot \phi_{i_2}^r(M_{j_2}) \quad j_1, j_2 = 1, 2, 3$$

and

determinants formed from rows of P_1, P_2, P_3 .

As before, the determinants cannot be involved, since we assume $3 = k < N - n$. Then it is easy to see that no non-zero polynomial in the other terms can be multilinear in (M_1, M_2, M_3) . So $\Omega^3(\mathfrak{h}^\perp)^H = 0$.

If $\eta \in \Omega^4(\mathfrak{h}^\perp)$ is invariant under $\{I\} \times \mathrm{SO}(N - n)$, then $\eta(M_1, \dots, M_4)$ can be written as a polynomial in the

$$\sum_r \phi_{i_1}^r(M_{j_1}) \cdot \phi_{i_2}^r(M_{j_2}) \quad j_1, j_2 = 1, \dots, 4$$

(determinants are ruled out as before). Since η is multilinear, it is easy to see that the only monomials which can appear are

$$\left\{ \sum_r \phi_{i_1}^r(M_{j_1}) \cdot \phi_{i_2}^r(M_{j_2}) \right\} \cdot \left\{ \sum_r \phi_{i_3}^r(M_{j_3}) \cdot \phi_{i_4}^r(M_{j_4}) \right\},$$

where j_1, \dots, j_4 are distinct. This term can be written

$$\left(\sum_r \phi_{i_1}^r \otimes \phi_{i_2}^r \right) \otimes \left(\sum_r \phi_{i_3}^r \otimes \phi_{i_4}^r \right) (M_{\pi(1)}, M_{\pi(2)}, M_{\pi(3)}, M_{\pi(4)})$$

for some permutation $\pi \in S_4$. Since η is alternating, we find that η is a linear combination of terms $\zeta_{i_1 i_2} \wedge \zeta_{i_3 i_4}$.

In general, we clearly have:

If $k < N - n$ is odd, then $\Omega^k(\mathfrak{h}^\perp)^H = 0$.

If $k < N - n$ is even, then all elements of $\Omega^k(\mathfrak{h}^\perp)^H$ can be written as linear combinations of the forms

$$\zeta_{i_1 i_2} \wedge \dots \wedge \zeta_{i_{k-1} i_k}.$$

To determine $\Omega^k(\mathfrak{h}^\perp)^H$ completely for all even $k < N - n$, we still have to consider invariance under $\mathrm{SO}(n) \times \{I\}$. But we already see, from Theorem 32, that

(A) If $k < N - n$ is odd, then $H^k(\tilde{G}_n(\mathbb{R}^N)) = 0$.

Moreover, the maps

$$\Omega^{k-1}(\mathfrak{h}^\perp)^H \xrightarrow{d} \Omega^k(\mathfrak{h}^\perp)^H \xrightarrow{d} \Omega^{k+1}(\mathfrak{h}^\perp)^H$$

are zero for even $k < N - n - 1$, since the vector spaces on the ends are 0. Consequently,

$$H^k(\tilde{G}_n(\mathbb{R}^N)) = \frac{\ker d: \Omega^k(\mathfrak{h}^\perp)^H}{d(\Omega^{k+1}(\mathfrak{h}^\perp)^H)} = \Omega^k(\mathfrak{h}^\perp)^H / 0 = \Omega^k(\mathfrak{h}^\perp)^H.$$

Actually, this result holds for *all* k , but we need a different argument. Notice that something special happens when we take the bracket of two elements of \mathfrak{h}^\perp . We have

$$\begin{aligned} \begin{pmatrix} 0 & P \\ -P^t & 0 \end{pmatrix} \begin{pmatrix} 0 & Q \\ -Q^t & 0 \end{pmatrix} &= \begin{pmatrix} 0 & Q \\ -Q^t & 0 \end{pmatrix} \begin{pmatrix} 0 & P \\ -P^t & 0 \end{pmatrix} \\ &= \begin{pmatrix} -PQ^t + QP^t & 0 \\ 0 & -P^tQ + QP^t \end{pmatrix}, \end{aligned}$$

which is in \mathfrak{h} . Consulting the statement of Theorem 32 we see that our map

$$d: \Omega^k(\mathfrak{h}^\perp)^H \rightarrow \Omega^{k+1}(\mathfrak{h}^\perp)^H$$

is *always* 0. Thus

$$(B) \quad \text{For all } k \text{ we have } H^k(\tilde{G}_n(\mathbb{R}^N)) = \Omega^k(\mathfrak{h}^\perp)^H.$$

We now have to investigate linear combinations of the forms $\zeta_{i_1 i_2} \wedge \cdots \wedge \zeta_{i_{k-1} i_k}$. Such combinations can be described in terms of polynomial functions $f: \mathfrak{o}(n) \rightarrow \mathbb{R}$ which are homogeneous of degree $k/2$: if f is a sum of monomials

$$c \cdot \phi_{i_2}^{i_1} \cdot \phi_{i_4}^{i_3} \cdots \phi_{i_k}^{i_{k-1}} \quad 1 \leq i_{2\alpha-1} < i_{2\alpha} \leq n,$$

then $f(\zeta) \in \Omega^k(\mathfrak{h}^\perp)$ will denote the k -form which is the sum of the corresponding terms

$$c \cdot \zeta_{i_1 i_2} \wedge \zeta_{i_3 i_4} \wedge \cdots \wedge \zeta_{i_{k-1} i_k}$$

(since the ζ_{ij} are 2-forms, the \wedge products commute, so the order of the factors ϕ_j^i is irrelevant). Clearly every linear combination of the forms $\zeta_{i_1 i_2} \wedge \cdots \wedge \zeta_{i_{k-1} i_k}$ is $f(\zeta)$ for some $f: \mathfrak{o}(n) \rightarrow \mathbb{R}$. Since the ϕ_i^j are linearly independent, this f is unique for $k < N-n$. Moreover, for homogeneous polynomials $f, g: \mathfrak{o}(n) \rightarrow \mathbb{R}$ we have

$$(1) \quad (fg)(\zeta) = f(\zeta) \wedge g(\zeta).$$

We want to find out how $\text{SO}(n) \times \{I\}$ operates on $f(\zeta)$. Take first the special case $f = \phi_j^i$, so that $f(\zeta) = \phi_j^i(\zeta) = \zeta_{ij}$. For

$$\begin{aligned} \tilde{A} &= \begin{pmatrix} A & 0 \\ 0 & I \end{pmatrix} \in \text{SO}(n) \times \{I\} \\ M_1 &= \begin{pmatrix} 0 & P_1 \\ -P_1^t & 0 \end{pmatrix}, \quad M_2 = \begin{pmatrix} 0 & P_2 \\ -P_2^t & 0 \end{pmatrix} \in \mathfrak{h}^\perp \end{aligned}$$

we have

$$\begin{aligned}
& [\text{Ad}(\tilde{A})^* \zeta_{ij}](M_1, M_2) \\
&= \sum_r \phi_i^r \wedge \phi_j^r (\text{Ad}(\tilde{A}) M_1, \text{Ad}(\tilde{A}) M_2) \\
&= \sum_r \left\{ \phi_i^r \begin{pmatrix} 0 & AP_1 \\ -P_1^t A^t & 0 \end{pmatrix} \cdot \phi_j^r \begin{pmatrix} 0 & AP_2 \\ -P_2^t A^t & 0 \end{pmatrix} - \cdots \right\} \\
&= \sum_r \{ (AP_1)_{ir} (AP_2)_{jr} - (AP_2)_{ir} (AP_1)_{jr} \} \\
&= \sum_r \sum_{\mu, v=1}^n \{ A_{i\mu} (P_1)_{\mu r} A_{jv} (P_2)_{vr} - A_{i\mu} (P_2)_{\mu r} A_{jv} (P_1)_{vr} \} \\
&= \sum_{\mu, v=1}^n A_{i\mu} A_{jv} \left[\sum_r (P_1)_{\mu r} (P_2)_{vr} - (P_2)_{\mu r} (P_1)_{vr} \right],
\end{aligned}$$

and hence

$$\text{Ad}(\tilde{A})^* \zeta_{ij} = \sum_{\mu, v=1}^n A_{i\mu} A_{jv} \zeta_{\mu v},$$

or

$$(2) \quad \text{Ad}(\tilde{A})^* (\phi_j^i(\zeta)) = \left(\sum_{\mu, v=1}^n A_{i\mu} A_{jv} \phi_v^\mu \right) (\zeta).$$

On the other hand, for a matrix $L \in \mathfrak{o}(n)$ we have

$$\begin{aligned}
(3) \quad \phi_j^i(\text{Ad}(A)L) &= \phi_j^i(ALA^t) = \sum_{\mu, v=1}^n A_{i\mu} A_{jv} L_v^\mu \\
&\implies \phi_j^i \circ \text{Ad}(A) = \sum_{\mu, v=1}^n A_{i\mu} A_{jv} \phi_v^\mu.
\end{aligned}$$

Comparing (2) and (3), we see that

$$\text{Ad}(\tilde{A})^* (\phi_j^i(\zeta)) = [\phi_j^i \circ \text{Ad}(A)](\zeta).$$

Using equation (1), we find that for all $f: \mathfrak{o}(n) \rightarrow \mathbb{R}$ we have

$$(*) \quad \text{Ad}(\tilde{A})^* f(\zeta) = [f \circ \text{Ad}(A)](\zeta).$$

From equation (*) we see that a linear combination $f(\zeta)$ is invariant under all $\text{Ad}(\tilde{A})^*$, and thus $f(\zeta) \in \Omega^k(\mathfrak{h}^\perp)^H \approx H^k(\tilde{G}_n(\mathbb{R}^N))$, if and only if $f: \mathfrak{o}(n) \rightarrow \mathbb{R}$ is invariant under all $\text{Ad}(A)$, for $A \in \text{SO}(n)$. But Theorem 40 says that all such f are polynomials in

$$\begin{aligned} f_2, \dots, f_{2[n/2]} & \quad \text{if } n \text{ is odd} \\ f_2, \dots, f_{n-2}, \text{Pf} & \quad \text{if } n \text{ is even.} \end{aligned}$$

Moreover, f is uniquely expressible as such a polynomial, since $f_2, \dots, f_{2[n/2]}$ [or $f_2, \dots, f_{n-2}, \text{Pf}$] are algebraically independent (pages 334 and 336).

Case 1. n is odd. The forms $f_2(\zeta), \dots, f_{2[n/2]}(\zeta)$ have dimensions $4, 8, \dots, 4[n/2]$. So

If $k < N - n$ is not a multiple of 4, then $H^k(\tilde{G}_n(\mathbb{R}^N)) = 0$.

If $k < N - n$ is a multiple of 4, then every element of $H^k(\tilde{G}_n(\mathbb{R}^N))$ is a unique linear combination of cup products of the classes corresponding, via Theorem 32, to the forms

$$f_2(\zeta), \dots, f_{k/4}(\zeta).$$

Case 2. n is even. The forms $f_2(\zeta), \dots, f_{n-2}(\zeta), \text{Pf}(\zeta)$ have dimensions $4, 8, \dots, 2n - 4, n$. So

If $k < N - n$ is odd, then $H^k(\tilde{G}_n(\mathbb{R}^N)) = 0$.

If $k < N - n$ is even, then every element of $H^k(\tilde{G}_n(\mathbb{R}^N))$ is a unique linear combination of cup products of the classes corresponding, via Theorem 32, to the forms

$$f_2(\zeta), \dots, f_{[k/4]}(\zeta), \quad \text{and} \quad \text{Pf}(\zeta) \quad \text{if } k \geq n.$$

This can all be said more prettily if we fix n and allow N to increase:

41. PROPOSITION. If $\alpha: \tilde{G}_n(\mathbb{R}^N) \rightarrow \tilde{G}_n(\mathbb{R}^M)$ is the natural map, and we have $M > N > n + k$, then the induced map

$$\alpha^*: H^k(\tilde{G}_n(\mathbb{R}^M)) \rightarrow H^k(\tilde{G}_n(\mathbb{R}^N))$$

is an isomorphism.

PROOF. Because of the preceding discussion, it obviously suffices to show that the element of $H^k(\tilde{G}_n(\mathbb{R}^M))$ corresponding to f_r goes by α^* to the element in $H^k(\tilde{G}_n(\mathbb{R}^N))$ corresponding to f_r . Proving this is just a matter of unraveling definitions, and will provide a good opportunity to set straight everything done up till now. ♦

Henceforth we consider only N sufficiently large so that $4[n/2] < N - n$ for odd n , and $2n - 4 < N - n$ and $n < N - n$ for even n (we can take $N > 3n - 2$ in both cases). Then all elements of $H^*(\tilde{G}_n(\mathbb{R}^N))$ in dimensions $< N - n$ are unique linear combinations of cup products of the classes corresponding to

$$\begin{array}{ll} f_2(\zeta), \dots, f_{2[n/2]}(\zeta) & n \text{ odd} \\ f_2(\zeta), \dots, f_{n-2}(\zeta), \text{Pf}(\zeta) & n \text{ even.} \end{array}$$

We let

$$p_{n;k} \in H^{4k}(\tilde{G}_n(\mathbb{R}^N)) \quad k = 1, \dots, [n/2]$$

be the class corresponding to

$$\frac{1}{(2\pi)^{2k}} f_{2k}(\zeta),$$

and we let

$$e_n \in H^n(\tilde{G}_n(\mathbb{R}^N)) \quad n = 2m$$

be the class corresponding to

$$\frac{1}{(2\pi)^m} \text{Pf}(\zeta).$$

We defined $p_{n;k}$ for $k = 1, \dots, [n/2]$ for both odd and even n , just for simplicity. For even n this gives us the extra class $p_{n;n/2}$, corresponding to $f_n(\zeta)/(2\pi)^n$. It satisfies

$$p_{n;n/2} = e_n \cup e_n,$$

since $e_n \cup e_n$ corresponds to

$$\begin{aligned} \frac{1}{(2\pi)^m} \text{Pf}(\zeta) \wedge \frac{1}{(2\pi)^m} \text{Pf}(\zeta) &= \frac{1}{(2\pi)^n} \text{Pf}^2(\zeta) \quad \text{by equation (1) on page 341} \\ &= \frac{1}{(2\pi)^n} \det(\zeta) = \frac{1}{(2\pi)^n} f_n(\zeta). \end{aligned}$$

In these definitions, we are always taking N large, and applying Proposition 41, so that there is no need to have an extra subscript N on the symbols $p_{n;k}$ and e_n .

In accordance with our discussion in section 5, each class

$$p_{n;k} \in H^{4k}(\tilde{G}_n(\mathbb{R}^N)) \quad N \text{ large}$$

determines a “characteristic class”, that is, a function

$$\xi \mapsto p_{n;k}(\xi) \in H^{4k}(M)$$

which assigns to a smooth oriented n -dimensional bundle $\xi = \pi: E \rightarrow M$ an element of the cohomology of M . Explicitly,

$$p_{n;k}(\xi) = g^* p_{n;k}$$

where

$$g: M \rightarrow \tilde{G}_n(\mathbb{R}^N) \quad \text{satisfies} \quad g^* \tilde{\gamma}^n(\mathbb{R}^N) \simeq \xi.$$

This characteristic class is called the k^{th} **Pontryagin class** for n -dimensional bundles. For even n , we have the additional class

$$\xi \mapsto e_n(\xi).$$

When one is dealing with characteristic classes, the number n is usually apparent, since it is the fibre dimension of the bundle whose characteristic class is being considered. Consequently, we write simply $p_k(\xi)$ and $e(\xi)$. If ξ has fibre dimension n , then $p_k(\xi)$ is defined for $k = 1, \dots, [n/2]$; if n is even, then we also have the class $e(\xi)$, and $p_{n/2}(\xi) = e(\xi) \cup e(\xi)$.

Since all elements of $H^*(\tilde{G}_n(\mathbb{R}^N))$ in dimensions $< N - n$ are linear combinations of the $p_{n;k}$ and e_n , we see that *all* characteristic classes for oriented n -dimensional bundles are polynomials in the Pontryagin classes p_k , together with e if n is even. In particular, the Euler class must be representable in this way, and our notation clearly suggests that the Euler class is, in fact, just the characteristic class e . In order to prove this, we have to look a little more carefully at the universal bundles.

Consider the universal bundle $\tilde{\gamma}^n(\mathbb{R}^N) = \pi: E(\tilde{\gamma}^n(\mathbb{R}^N)) \rightarrow \tilde{G}_n(\mathbb{R}^N)$. A point of $\tilde{G}_n(\mathbb{R}^N)$ is an oriented n -dimensional subspace $W \subset \mathbb{R}^N$, and the fibre $\pi^{-1}(W)$ over W is $\{(W, w) : w \in W\}$. So there is a natural Riemannian metric $\langle \cdot, \cdot \rangle$ on $\tilde{\gamma}^n(\mathbb{R}^N)$: the inner product of $(W, w_1), (W, w_2) \in \pi^{-1}(W)$ is just the usual inner product of $w_1, w_2 \in \mathbb{R}^N$. For the corresponding principal bundle $\varpi: \text{SO}(E(\tilde{\gamma}^n(\mathbb{R}^N))) \rightarrow \tilde{G}_n(\mathbb{R}^N)$, the fibre $\varpi^{-1}(W)$ is the set of all $(W, (w_1, \dots, w_n))$, where (w_1, \dots, w_n) is a positively oriented orthonormal n -frame in $W \subset \mathbb{R}^N$. Now we can define a map $\lambda: \text{SO}(N) \rightarrow \text{SO}(E(\tilde{\gamma}^n(\mathbb{R}^N)))$,

from the special orthogonal group $\mathrm{SO}(N)$ to the total space of this principal bundle, as follows: If $W_0 \subset \mathbb{R}^N$ is the subspace spanned by e_1, \dots, e_n , then

$$\lambda(A) = (A(W_0), (A(e_1), \dots, A(e_n))).$$

It is easy to see that for the point $x = (W_0, (e_1, \dots, e_n)) \in \mathrm{SO}(E(\tilde{\gamma}^n(\mathbb{R}^N)))$, we have

$$\lambda^{-1}(x) = \{I\} \times \mathrm{SO}(N - n);$$

more generally, for any $x \in \mathrm{SO}(E(\tilde{\gamma}^n(\mathbb{R}^N)))$ the set $\lambda^{-1}(x)$ is a left coset of $\{I\} \times \mathrm{SO}(N - n)$. So $\mathrm{SO}(E(\tilde{\gamma}^n(\mathbb{R}^N)))$ can be identified with the left coset space

$$\mathrm{SO}(N)/\{I\} \times \mathrm{SO}(N - n).$$

We leave it as an exercise for the reader to show that the topology and C^∞ structure on $\mathrm{SO}(E(\tilde{\gamma}^n(\mathbb{R}^N)))$ is the same as that on this left coset space, and that the projection

$$\varpi: \mathrm{SO}(N)/\{I\} \times \mathrm{SO}(N - n) \rightarrow \mathrm{SO}(N)/\mathrm{SO}(n) \times \mathrm{SO}(N - n)$$

is just the natural map taking the coset $A \cdot [\{I\} \times \mathrm{SO}(N - k)]$ to the coset $A \cdot [\mathrm{SO}(k) \times \mathrm{SO}(N - k)]$. Notice that the diagram

$$\begin{array}{ccc} \mathrm{SO}(N) & \xrightarrow{\pi_1} & \frac{\mathrm{SO}(N)}{\{I\} \times \mathrm{SO}(N - n)} \\ & \searrow \pi_2 & \downarrow \varpi \\ & & \frac{\mathrm{SO}(N)}{\mathrm{SO}(n) \times \mathrm{SO}(N - n)} \end{array}$$

commutes, where π_1 and π_2 are the natural projections. As in section 6, we will use L_A for the left multiplication $L_A: \mathrm{SO}(N) \rightarrow \mathrm{SO}(N)$, and \mathbf{L}_A for the diffeomorphism of $\mathrm{SO}(N)/\{I\} \times \mathrm{SO}(N - n)$ taking the coset $B \cdot [\{I\} \times \mathrm{SO}(N - n)]$ to $AB \cdot [\{I\} \times \mathrm{SO}(N - n)]$. We also have the map $R_A: \mathrm{SO}(N) \rightarrow \mathrm{SO}(N)$, and the map \mathbf{R}_A taking the coset $B \cdot [\{I\} \times \mathrm{SO}(N - n)]$ to $BA \cdot [\{I\} \times \mathrm{SO}(N - n)]$. The reader should check that for $A \in \mathrm{SO}(n)$, the map \mathbf{R}_A corresponds to the right multiplication by A in the principal bundle $\mathrm{SO}(\tilde{\gamma}^n(\mathbb{R}^N))$.

On $\mathrm{SO}(N)$ we have the left invariant 1-forms $\tilde{\phi}_\alpha^\beta$ ($\alpha < \beta$) whose values at $I \in \mathrm{SO}(N)$ are the elements $\phi_\alpha^\beta \in \mathfrak{o}(N)^*$; set $\tilde{\phi}_\alpha^\beta = -\tilde{\phi}_\beta^\alpha$ for $\alpha > \beta$, and $\tilde{\phi}_\alpha^\alpha = 0$. We claim that for $i, j \leq n$ there are unique 1-forms ω_j^i on $\mathrm{SO}(N)/\{I\} \times \mathrm{SO}(N - n)$ such that

$$(1) \quad \pi_1^* \omega_j^i = \tilde{\phi}_j^i.$$

To prove this we first note that π_{1*} is always onto. Since we need to have

$$(2) \quad \omega_j^i(\pi_{1*}X) = \tilde{\phi}_j^i(X)$$

for all tangent vectors X of $\mathrm{SO}(N)$, this proves uniqueness. To prove existence, we need to show that definition (2) is well-defined, by showing that $\tilde{\phi}_j^i(X) = 0$ whenever $\pi_{1*}X = 0$. So suppose $X \in \mathrm{SO}(N)_A$. Then $X = L_{A*}X_I$ for some $X_I \in \mathfrak{o}(N)$. Since $\pi_1 \circ L_A = \mathbf{L}_A \circ \pi_1$, we see that

$$\begin{aligned} \pi_{1*}X = 0 &\implies \pi_{1*}L_{A*}X_I = 0 \\ &\implies \mathbf{L}_{A*}\pi_{1*}X_I = 0 \\ &\implies \pi_{1*}X_I = 0 \quad \text{since } \mathbf{L}_A \text{ is a diffeomorphism} \\ &\implies X_I \text{ is of the form } \begin{pmatrix} 0 & 0 \\ 0 & * \end{pmatrix} \\ &\implies \phi_j^i(X_I) = 0 \\ &\implies \tilde{\phi}_j^i(X) = 0 \quad \text{since } \tilde{\phi}_j^i \text{ is left invariant.} \end{aligned}$$

Thus the forms ω_j^i exist. Note that

$$\begin{aligned} \mathbf{L}_A^*\omega_j^i(\pi_{1*}X) &= \omega_j^i(\mathbf{L}_{A*}\pi_{1*}X) \\ &= \omega_j^i(\pi_{1*}L_{A*}X) \\ &= \tilde{\phi}_j^i(L_{A*}X) \\ &= \tilde{\phi}_j^i(X) = \omega_j^i(\pi_{1*}X). \end{aligned}$$

So

$$\mathbf{L}_A^*\omega_j^i = \omega_j^i.$$

Now $\omega = (\omega_j^i)$ is an $\mathfrak{o}(n)$ -valued 1-form on $\mathrm{SO}(N)/\{I\} \times \mathrm{SO}(N-n)$. We claim that ω is, in fact, a connection on the principal bundle $\varpi: \mathrm{SO}(N)/\{I\} \times \mathrm{SO}(N-n) \rightarrow \mathrm{SO}(N)/\mathrm{SO}(n) \times \mathrm{SO}(N-n)$. We have to check that

$$\begin{aligned} \omega(\sigma(M)) &= M && \text{for } M \in \mathfrak{o}(n) \\ \omega(\mathbf{R}_{A*}Y) &= A^{-1}\omega(Y)A && \text{for } A \in \mathrm{SO}(n) \text{ and } Y \text{ a tangent} \\ &&& \text{vector on } \mathrm{SO}(N)/\{I\} \times \mathrm{SO}(N-n). \end{aligned}$$

Recall that the value of $\sigma(M)$ at the coset $B \cdot [\{I\} \times \mathrm{SO}(N-n)]$ is $c'(0)$ where

$$\begin{aligned} c(t) &= \mathbf{R}_{\exp t M}(B \cdot [\{I\} \times \mathrm{SO}(N-n)]) \\ &= B(\exp t M) \cdot [\{I\} \times \mathrm{SO}(N-n)] \\ &= \pi_1 L_B(\exp t M) \\ \implies c'(0) &= \pi_{1*}L_{B*}M. \end{aligned}$$

Thus

$$\begin{aligned}
 \omega_j^i(\sigma(M) \text{ at } B \cdot [\{I\} \times \text{SO}(N-n)]) &= \omega_j^i(c'(0)) \\
 &= \omega_j^i(\pi_{1*}L_{B*}M) \\
 &= \tilde{\omega}_j^i(L_{B*}M) \\
 &= \phi_j^i(M) = M_j^i,
 \end{aligned}$$

which proves the first condition. To prove the second, take a tangent vector Y at the coset $B \cdot [\{I\} \times \text{SO}(N-n)]$ and choose a tangent vector $X \in \mathfrak{o}(N)_B$ with $\pi_{1*}X = Y$. Then

$$\omega_j^i(Y) = \omega_j^i(\pi_{1*}X) = \tilde{\phi}_j^i(X) = \phi_j^i(L_{B^{-1}*}X),$$

while

$$\begin{aligned}
 \omega_j^i(\mathbf{R}_{A*}Y) &= \omega_j^i(\mathbf{R}_{A*}\pi_{1*}X) = \omega_j^i(\pi_{1*}R_{A*}X) \\
 &= \tilde{\phi}_j^i(R_{A*}X) && R_{A*}X \text{ a tangent vector at } BA \\
 &= \phi_j^i(L_{(BA)^{-1}*}R_{A*}X) \\
 &= \phi_j^i(L_{A^{-1}*}R_{A*}L_{B^{-1}*}X) \\
 &= \phi_j^i(\text{Ad}(A^{-1})L_{B^{-1}*}X) \\
 &= \phi_j^i(A^{-1}(L_{B^{-1}*}X)A) \\
 &= \sum_{\mu, \nu=1}^k (A^{-1})_{\mu}^i \phi_j^i(L_{B^{-1}*}X)_{\nu}^{\mu} A_j^{\nu} \quad \text{by linearity of } \phi_j^i,
 \end{aligned}$$

which proves the second condition.

It is easy to see which vectors $\pi_{1*}X$ are vertical or horizontal when $X \in \mathfrak{o}(N)$. First of all,

$$\begin{aligned}
 \pi_{1*}X \text{ is vertical} &\iff \varpi_*\pi_{1*}X = 0 \\
 &\iff \pi_{2*}X = 0 \\
 &\iff X \in \mathfrak{o}(n) \times \mathfrak{o}(N-n).
 \end{aligned}$$

On the other hand,

$$\begin{aligned}
 \pi_{1*}X \text{ is horizontal} &\iff \text{all } \omega_j^i(\pi_{1*}X) = 0 \\
 &\iff \text{all } \omega_j^i(X) = 0 \\
 &\iff X \text{ has the form } \begin{pmatrix} 0 & 0 \\ 0 & * \end{pmatrix}.
 \end{aligned}$$

Given $X \in \mathfrak{o}(N)$, we write it as

$$\begin{aligned} X &= \begin{pmatrix} 0 & * \\ * & * \end{pmatrix} + \begin{pmatrix} * & 0 \\ 0 & 0 \end{pmatrix} \\ &= X_1 + X_2. \end{aligned}$$

Then $\pi_{1*}X_1$ is horizontal and $\pi_{1*}X_2$ is vertical. This means that the horizontal component of $\pi_{1*}X$ is precisely

$$h(\pi_{1*}X) = \pi_{1*}X_1.$$

To compute the curvature forms Ω_j^i for the connection ω_j^i , we use the fact (Problem 7-15) that the forms $\tilde{\phi}_\alpha^\beta$ satisfy

$$d\tilde{\phi}_\alpha^\beta = - \sum_{\gamma=1}^N \tilde{\phi}_\gamma^\beta \wedge \tilde{\phi}_\alpha^\gamma.$$

Then for $X, Y \in \mathfrak{o}(N)$ we have

$$\begin{aligned} \Omega_j^i(\pi_{1*}X, \pi_{1*}Y) &= d\omega_j^i(h\pi_{1*}X, h\pi_{1*}Y) \\ &= d\omega_j^i(\pi_{1*}X_1, \pi_{1*}Y_1) \\ &= d(\pi_1^*\omega_j^i)(X_1, Y_1) \\ &= d\tilde{\phi}_j^i(X_1, Y_1) \\ &= - \sum_{\gamma=1}^N \phi_\gamma^i \wedge \phi_j^\gamma(X_1, Y_1). \end{aligned}$$

Since

$$X_1 = X - \sum_{\alpha \text{ or } \beta > n} \phi_\alpha^\beta(X) \cdot X_\alpha^\beta, \quad Y_1 = Y - \sum_{\alpha \text{ or } \beta > n} \phi_\alpha^\beta(Y) \cdot X_\alpha^\beta,$$

this gives

$$\begin{aligned} \Omega_j^i(\pi_{1*}X, \pi_{1*}Y) &= \sum_r \phi_i^r \wedge \phi_j^r(X, Y) \\ &= \zeta_{ij}(X, Y), \end{aligned}$$

which shows that

$$(*) \quad \pi_1^*\Omega_j^i = \zeta_{ij} \quad \text{at } \text{SO}(N)_I.$$

(In fact, we also have $\pi_1^*\Omega_j^i = \tilde{\zeta}_{ij}$, where $\tilde{\zeta}_{ij}$ is the left invariant form extending ζ_{ij} , since the equation $\mathbf{L}_A^*\omega_j^i = \omega_j^i$ implies that we also have $\mathbf{L}_A^*\Omega_j^i = \Omega_j^i$.)

42. THEOREM. If ξ is an oriented n -dimensional bundle, with $n = 2m$ even, then the characteristic class $e(\xi)$ is the Euler class $\chi(\xi)$.

PROOF. It suffices to prove this when ξ is the universal bundle $\tilde{\gamma}^n(\mathbb{R}^N)$. We know, by Corollary 25 and Theorem 26, that the Euler class $\chi(\tilde{\gamma}^n(\mathbb{R}^N))$ is represented by the unique form Γ on $\text{SO}(N)/\text{SO}(n) \times \text{SO}(N - n)$ such that

$$\begin{aligned}\varpi^* \Gamma &= \frac{1}{\pi^m m! 2^n} \sum_{i_1, \dots, i_n} \varepsilon^{i_1 \dots i_n} \Omega_{i_2}^{i_1} \wedge \dots \wedge \Omega_{i_n}^{i_{n-1}} \\ &= \frac{1}{\pi^m m! 2^n} 2^m \cdot m! \text{Pf}(\Omega) \\ &= \frac{1}{(2\pi)^m} \text{Pf}(\Omega).\end{aligned}$$

We want to show that Γ corresponds, via Theorem 32, to the form

$$\frac{1}{(2\pi)^m} \text{Pf}(\zeta).$$

Note first that if L'_A is the diffeomorphism of $\text{SO}(N)/\text{SO}(n) \times \text{SO}(N - n)$ taking the coset $B \cdot [\text{SO}(n) \times \text{SO}(N - n)]$ to $AB \cdot [\text{SO}(n) \times \text{SO}(N - n)]$, then $L'_A \circ \varpi = \varpi \circ L_A$. So

$$\begin{aligned}\varpi^*(L'_A{}^* \Gamma) &= L_A{}^* \varpi^* \Gamma = \frac{1}{(2\pi)^m} L_A{}^* \text{Pf}(\Omega) \\ &= \frac{1}{(2\pi)^m} \text{Pf}(L_A{}^* \Omega) = \frac{1}{(2\pi)^m} \text{Pf}(\Omega) \\ &= \varpi^* \Gamma.\end{aligned}$$

By uniqueness in Proposition 18 we have $L'_A{}^* \Gamma = \Gamma$ for all $A \in \text{SO}(N)$. In other words, Γ is an invariant form on $\text{SO}(N)/\text{SO}(n) \times \text{SO}(N - n)$, as defined in section 6. So the element of $\Omega^n(\mathfrak{o}(N))$ corresponding to Γ in Theorem 32 is simply $\pi_2^* \Gamma$ at I . But

$$\begin{aligned}\pi_2^* \Gamma &= \pi_1^* \varpi^* \Gamma \\ &= \frac{1}{(2\pi)^m} \pi_1^* \text{Pf}(\Omega) = \frac{1}{(2\pi)^m} \text{Pf}(\pi_1^* \Omega) \\ &= \frac{1}{(2\pi)^m} \text{Pf}(\zeta) \quad \text{at } I, \quad \text{by equation (*).} \quad \blacklozenge\end{aligned}$$

The classes $p_k(\xi)$ of an oriented bundle $\xi = \pi: E \rightarrow M$ may be described in exactly the same way: Choose a Riemannian metric $\langle \cdot, \cdot \rangle$ for ξ , form the principal bundle $O(\xi) = \varpi: O(E) \rightarrow M$, and let ω be a connection on $O(E)$, with curvature form Ω .

43. THEOREM. There is a unique $4k$ -form Λ on M such that

$$\varpi^* \Lambda = \frac{1}{(2\pi)^{2k}} f_{2k}(\Omega).$$

This form Λ is closed, and the cohomology class $[\Lambda]$ is independent of the choice of the Riemannian metric $\langle \cdot, \cdot \rangle$ and the connection ω in terms of which Λ is defined. The cohomology class $[\Lambda]$ is precisely $p_k(\xi)$.

PROOF. The proofs of Propositions 18, 19, and 20 can be adapted, essentially without modification, to prove the first two assertions. The proof of the final assertion is exactly like the proof of Theorem 42. ♦

As a simple application, we consider a Riemannian manifold $(M, \langle \cdot, \cdot \rangle)$ of constant curvature K_0 . Then the curvature form Ω on $O(TM)$ satisfies

$$\Omega_j^i = K_0 \theta^i \wedge \theta^j.$$

To calculate $f_{2k}(\Omega)$, we use the explicit formula given in Problem I.7-14, to obtain

$$\begin{aligned} f_{2k}(\Omega) &= \frac{1}{(2k)!} \sum_{\substack{i_1 \dots i_{2k} \\ j_1 \dots j_{2k}}} \Omega_{i_1}^{j_1} \wedge \dots \wedge \Omega_{i_{2k}}^{j_{2k}} \delta_{j_1 \dots j_{2k}}^{i_1 \dots i_{2k}} \\ &= \frac{(K_0)^{2k}}{(2k)!} \sum_{\substack{i_1 \dots i_{2k} \\ j_1 \dots j_{2k}}} \theta^{j_1} \wedge \theta^{i_1} \wedge \dots \wedge \theta^{j_{2k}} \wedge \theta^{i_{2k}} \delta_{j_1 \dots j_{2k}}^{i_1 \dots i_{2k}}. \end{aligned}$$

In this sum, the δ term vanishes unless j_1, \dots, j_{2k} is a permutation of i_1, \dots, i_{2k} ; but then $\theta^{j_1} \wedge \dots \wedge \theta^{i_{2k}}$ has repeated factors, so it vanishes. Thus,

44. COROLLARY. If M^n is a compact manifold of constant curvature, then

$$p_k(TM) = 0, \quad k = 1, \dots, [n/4].$$

Another application of Theorem 43 gives us an analogue of Theorem 17. For a bundle ξ over M we define the **total Pontryagin class** $p(\xi)$ to be the element of $H^0(M) \oplus H^4(M) \oplus \dots$ given by

$$p(\xi) = 1 + p_1(\xi) + \dots + p_{[n/2]}(\xi) = p_0(\xi) + p_1(\xi) + \dots + p_{[n/2]}(\xi),$$

where $1 \in H^0(M)$ is the standard element (represented by the constant function 1 on M).

45. THEOREM. If ξ and η are oriented bundles over the same compact manifold M , then the total Pontryagin class of $\xi \oplus \eta$ is given by the **Whitney product formula**

$$p(\xi \oplus \eta) = p(\xi) \cup p(\eta).$$

[This means that

$$p_k(\xi \oplus \eta) = \sum_{l=0}^k p_l(\xi) \cup p_{k-l}(\eta),$$

when we look at individual components.]

PROOF. The proof will be almost exactly like the proof of Theorem 22. For convenience we rename our bundles ξ and η as $\xi_i = \pi_i: E_i \rightarrow M$ for $i = 1, 2$, and let $\xi_1 \oplus \xi_2 = \pi: E \rightarrow M$. We introduce the corresponding principal bundles $\varpi_i: \text{SO}(E_i) \rightarrow M$ and $\varpi: \text{SO}(E) \rightarrow M$, the principal bundle $\text{SO}(E_1) * \text{SO}(E_2) \rightarrow M$, and the projections $\rho_i: \text{SO}(E_1) * \text{SO}(E_2) \rightarrow \text{SO}(E_i)$. Choose connections ω_i on $\text{SO}(E_i)$, with curvature forms Ω_i . Then

$$\rho_1^* \omega_1 \oplus \rho_2^* \omega_2 = \begin{pmatrix} \rho_1^* \omega_1 & 0 \\ 0 & \rho_2^* \omega_2 \end{pmatrix}$$

is a connection $\bar{\omega}$ on $\text{SO}(E_1) * \text{SO}(E_2)$, with curvature form

$$\bar{\Omega} = \rho_1^* \Omega_1 \oplus \rho_2^* \Omega_2 = \begin{pmatrix} \rho_1^* \Omega_1 & 0 \\ 0 & \rho_2^* \Omega_2 \end{pmatrix},$$

and $\bar{\omega}$ can be extended uniquely to a connection $\tilde{\omega}$ on $\text{SO}(E)$. At a point $e \in \text{SO}(E_1) * \text{SO}(E_2)$ we have

$$\tilde{\Omega} = \bar{\Omega} \quad (\text{on tangent vectors to } \text{SO}(E_1) * \text{SO}(E_2))$$

which implies that

$$\begin{aligned} f_{2k}(\tilde{\Omega}) &= f_{2k}(\bar{\Omega}) = \sum_{l=0}^k f_{2l}(\rho_1^* \Omega_1) \wedge f_{2k-2l}(\rho_2^* \Omega_2) \\ &\quad \text{by the formula on page 337} \\ &= \sum_{l=0}^k \rho_1^* f_{2l}(\Omega_1) \wedge \rho_2^* f_{2k-2l}(\Omega_2). \end{aligned}$$

So if Λ_k is the form representing $p_{2k}(\xi_1 \oplus \xi_2)$ while Υ_l^i are the forms representing $p_{2l}(\xi_i)$, then at e we have [on tangent vectors to $\mathrm{SO}(E_1) * \mathrm{SO}(E_2)$]

$$\begin{aligned} \varpi^* \Lambda_k &= \frac{1}{(2\pi)^{2k}} f_{2k}(\tilde{\Omega}) = \sum_{l=0}^k \frac{1}{(2\pi)^l} \rho_1^* f_{2l}(\Omega_1) \wedge \frac{1}{(2\pi)^{2k-l}} \rho_2^* f_{2k-2l}(\Omega_2) \\ &= \sum_{l=0}^k \rho_1^* \varpi_1^* \Upsilon_l^1 \wedge \rho_2^* \varpi_2^* \Upsilon_{k-l}^2 \\ &= \sum_{l=0}^k \varpi^* \Upsilon_l^1 \wedge \varpi^* \Upsilon_{k-l}^2. \end{aligned}$$

This implies that

$$\Lambda_k = \sum_{l=0}^k \Upsilon_l^1 \wedge \Upsilon_{k-l}^2. \quad \spadesuit$$

10. THE WEIL HOMOMORPHISM

The invariant polynomial functions $f_{2k}: \mathfrak{o}(n) \rightarrow \mathbb{R}$ and $\mathrm{Pf}: \mathfrak{o}(n) \rightarrow \mathbb{R}$ arose naturally in our attempts to calculate the cohomology of $\tilde{G}_n(\mathbb{R}^N)$; each one gave us an element of $H^*(\tilde{G}_n(\mathbb{R}^N))$, and hence a characteristic class $\xi \mapsto C(\xi)$ for oriented bundles. On the other hand, at the end of the last section we saw how these characteristic classes $C(\xi)$ could be defined directly for the bundle ξ , by means of a connection on the associated principal bundle $\mathrm{SO}(\xi)$. There is no reason why we cannot use exactly the same procedure for groups other than $\mathrm{SO}(n)$.

For any Lie group G , with Lie algebra \mathfrak{g} , we consider the set $\mathcal{P}(\mathfrak{g})$ of functions $f: \mathfrak{g} \rightarrow \mathbb{R}$ which can be expressed as polynomials in $\{\phi^\alpha\}$, where $\{\phi^\alpha\}$ is a basis of \mathfrak{g}^* . Such functions are called **polynomial functions** on \mathfrak{g} (the concept is clearly independent of the choice of basis $\{\phi_\alpha\}$), and the set of all homogeneous polynomial functions of degree k will be denoted by $\mathcal{P}^k(\mathfrak{g})$. We say that $f: \mathfrak{g} \rightarrow \mathbb{R}$ is **Ad(G)-invariant** if $f \circ \mathrm{Ad}(a) = f$ for all $a \in G$. Instead of considering polynomial functions on \mathfrak{g} it is often more convenient to consider the set $\mathcal{S}^k(\mathfrak{g})$ of symmetric k -linear maps $f: \mathfrak{g} \times \cdots \times \mathfrak{g} \rightarrow \mathbb{R}$. Given $f \in \mathcal{S}^k(\mathfrak{g})$, we define a polynomial function $\mathcal{P}f \in \mathcal{P}^k(\mathfrak{g})$ by

$$(\mathcal{P}f)(X) = f(X, \dots, X) \quad X \in \mathfrak{g}.$$

Conversely, given a basis ϕ^1, \dots, ϕ^r of \mathfrak{g} , and a polynomial function f of degree k on \mathfrak{g} , we can write it uniquely as

$$\sum_{\alpha_1, \dots, \alpha_k=1}^r a_{\alpha_1 \dots \alpha_k} \phi^{\alpha_1} \dots \phi^{\alpha_k}$$

where the $a_{\alpha_1 \dots \alpha_k}$ are symmetric in $\alpha_1, \dots, \alpha_k$; then we define $\mathcal{J}f \in \mathcal{J}^k(\mathfrak{g})$ by

$$(\mathcal{J}f)(X_1, \dots, X_k) = \sum a_{\alpha_1 \dots \alpha_k} \phi^{\alpha_1}(X_1) \dots \phi^{\alpha_k}(X_k), \quad X_1, \dots, X_k \in \mathfrak{g}.$$

It is easy to check that the maps

$$\mathcal{P}: \mathcal{J}^k(\mathfrak{g}) \rightarrow \mathcal{P}^k(\mathfrak{g}), \quad \mathcal{J}: \mathcal{P}^k(\mathfrak{g}) \rightarrow \mathcal{J}^k(\mathfrak{g})$$

are inverses to each other (so \mathcal{J} doesn't depend on the choice of basis). For $f \in \mathcal{J}^k(\mathfrak{g})$ and $g \in \mathcal{J}^l(\mathfrak{g})$ we define $fg \in \mathcal{J}^{k+l}(\mathfrak{g})$ by

$$\begin{aligned} fg(X_1, \dots, X_{k+l}) \\ = \frac{1}{(k+l)!} \sum_{\pi \in S_{k+l}} f(X_{\pi(1)}, \dots, X_{\pi(k)}) \cdot g(X_{\pi(k+1)}, \dots, X_{\pi(k+l)}). \end{aligned}$$

This makes $\mathcal{P}(fg) = \mathcal{P}(f) \cdot \mathcal{P}(g)$. We define $f \in \mathcal{J}^k(\mathfrak{g})$ to be **Ad(G)-invariant** if

$$\begin{aligned} f(\text{Ad}(a)X_1, \dots, \text{Ad}(a)X_k) &= f(X_1, \dots, X_k) \\ \text{for all } a \in G \text{ and } X_1, \dots, X_k \in \mathfrak{g}; \end{aligned}$$

then f is Ad(G)-invariant if and only if $\mathcal{P}f$ is Ad(G)-invariant. The set of all $f \in \mathcal{J}^k(\mathfrak{g})$ which are Ad(G)-invariant is denoted by $I^k(G)$. Thus, \mathcal{P} takes $I^k(G)$ into the set of polynomial functions on \mathfrak{g} which are Ad(G)-invariant, and \mathcal{J} takes this set back to $I^k(G)$.

Now let $\pi: P \rightarrow M$ be a principal bundle with group G , and let ω be a connection, with curvature form Ω . Thus both ω and Ω are \mathfrak{g} -valued, so if ϕ^1, \dots, ϕ^r is a basis of \mathfrak{g}^* , then we can write $\omega = \sum \omega^\alpha \cdot \phi^\alpha$ and $\Omega = \sum \Omega^\alpha \cdot \phi^\alpha$ for ordinary forms ω^α and Ω^α . Given $f \in \mathcal{P}^k(\mathfrak{g})$, we write it as a sum of terms

$$c \cdot \phi^{\alpha_1} \dots \phi^{\alpha_k},$$

and then let $f(\Omega)$ be the $2k$ -form on P which is the corresponding sum of terms

$$c \cdot \Omega^{\alpha_1} \wedge \dots \wedge \Omega^{\alpha_k}$$

(since the Ω^α are 2-forms, the order in the product $\phi^{\alpha_1} \dots \phi^{\alpha_k}$ is irrelevant). This is the definition used previously for the case $G = \mathrm{SO}(n)$, where the Lie algebra $\mathfrak{o}(n)$ has a natural basis $\{\phi_j^i\}_{i < j}$ (provided we use the convention that a polynomial in the ϕ_j^i ($i, j = 1, \dots, n$) be interpreted as a polynomial in the $\{\phi_j^i\}_{i < j}$ by replacing ϕ_i^j by $-\phi_j^i$ for $j > i$). A more intrinsic description is possible when we work with $f \in \mathcal{J}^k(\mathfrak{g})$. We now define $f(\Omega)$ to be the $2k$ -form on P given by

$$\begin{aligned} f(\Omega)(X_1, \dots, X_{2k}) \\ = \frac{1}{2^k} \sum_{\pi \in S_{2k}} (\mathrm{sgn} \pi) \cdot f(\Omega(X_{\pi(1)}, X_{\pi(2)}), \dots, \Omega(X_{\pi(2k-1)}, X_{\pi(2k)})), \end{aligned}$$

where X_1, \dots, X_{2k} are now tangent vectors of P . It can be checked that $(\mathcal{P}f)(\Omega) = f(\Omega)$ for $f \in \mathcal{J}^k(\mathfrak{g})$; equivalently, $(\mathcal{J}f)(\Omega) = f(\Omega)$ for $f \in \mathcal{P}^k(\mathfrak{g})$ (so the definition of $f(\Omega)$ doesn't depend on the choice of $\{\phi^\alpha\}$).

46. THEOREM. Let $\xi = \pi: P \rightarrow M$ be a principal bundle with group G , and let ω be a connection on P , with curvature form Ω . Then for every $f \in I^k(G)$ there is a unique $2k$ -form Λ on M such that

$$\pi^* \Lambda = f(\Omega).$$

The form Λ is closed, and its de Rham cohomology class $w_\xi(f) = [\Lambda]$ is independent of the choice of ω . For $f \in I^k(G)$ and $g \in I^l(G)$ we have $w_\xi(fg) = w_\xi(f) \cup w_\xi(g)$.

PROOF. Exactly like the proofs of Theorems 18, 19, and 20. ♦

If we set $H^*(M) = H^0(M) \oplus H^1(M) \oplus \dots$ and $I(G) = \mathbb{R} \oplus I^1(G) \oplus \dots$, then we have a homomorphism $w_\xi: I(G) \rightarrow H^*(M)$, depending only on the given principal bundle $\xi = \pi: P \rightarrow M$. This map is called the **Weil homomorphism**. It is natural, in the following sense.

47. PROPOSITION. Let $\pi: P \rightarrow M$ be a principal bundle with group G and let $f: M' \rightarrow M$ be a smooth map, inducing the map $f^*: H^*(M) \rightarrow H^*(M')$. Then

$$w_{f^*\xi} = f^* \circ w_\xi.$$

PROOF. An elementary exercise (just like the proof of Proposition 21). ♦

If we take $G = \mathrm{SO}(n)$ in Theorem 46, and consider the functions $g_{2k} = \delta(f_{2k}) \in I^{2k}(\mathrm{SO}(n))$ corresponding to the polynomial functions f_{2k} on $\mathfrak{o}(n)$, then we have classes $w_\eta(g_{2k}) \in H^{4k}(M)$ for any principal $\mathrm{SO}(n)$ bundle η over M . If $\xi = \pi: E \rightarrow M$ is an oriented n -dimensional vector bundle over M , then we can form the principal bundle $\eta = \mathrm{SO}(\xi)$ by means of a Riemannian metric on ξ [all such η are equivalent by Corollary 5], and Theorem 43 amounts to the assertion that $w_\eta(g_{2k}) = p_k(\xi)$. Notice that the $\mathrm{SO}(n)$ -invariant polynomials f_{2k} on $\mathfrak{o}(n)$ are also $\mathrm{GL}(n, \mathbb{R})$ -invariant polynomials on $\mathfrak{gl}(n, \mathbb{R})$. So there are corresponding $g'_{2k} \in I^{2k}(\mathrm{GL}(n, \mathbb{R}))$ which restrict to g_{2k} on $\mathfrak{o}(n) \times \cdots \times \mathfrak{o}(n)$. Now a connection ω for the principal bundle $\eta = \mathrm{SO}(\xi)$ extends to a connection ω' for the principal bundle $\eta' = F(\xi)$ of frames of ξ , and Ω' is an extension of Ω . Thus the form

$$g'_{2k}(\Omega') \quad \text{restricts to} \quad g_{2k}(\Omega) \quad \text{on} \quad \mathrm{SO}(E).$$

This shows that $w_{\eta'}(g'_{2k}) = w_\eta(g_{2k}) = p_k(\xi)$. Since $w_{\eta'}(g'_{2k})$ doesn't depend on the particular connection Ω' for $F(\xi)$, we see that we can define $p_k(\xi)$ in terms of an arbitrary connection for $F(\xi)$; it is not necessary to use a connection which preserves inner products, and our bundle does not even have to be orientable.

On the other hand, for $n = 2m$, the Pfaffian $\mathrm{Pf}: \mathfrak{o}(n) \rightarrow \mathbb{R}$ is *not* $\mathrm{GL}(n, \mathbb{R})$ -invariant, nor even $\mathrm{GL}^+(n, \mathbb{R})$ -invariant, so our construction definitely requires orientability, and a connection on $\mathrm{SO}(E)$, i.e., a connection compatible with some metric. Indeed, there are examples (see Milnor and Stasheff [1; pg. 312]) of oriented bundles ξ having a connection ω with $\Omega = 0$, but with $\chi(\xi) \neq 0$; naturally such a connection cannot be compatible with any metric on ξ .

11. COMPLEX BUNDLES

A **complex vector bundle** $\pi: E \rightarrow X$ is defined precisely like a real vector bundle, except that each fibre $\pi^{-1}(x)$ has the structure of a vector space over \mathbb{C} , and in all the conditions for a vector bundle, including local triviality, we replace \mathbb{R} by \mathbb{C} whenever it occurs; vector space isomorphisms are always understood to be isomorphisms of complex vector spaces, hence linear over \mathbb{C} . Linearity over \mathbb{C} is also understood in the definitions of bundle maps (and equivalences) between complex bundles. The Whitney sum $\xi \oplus \eta$ of two complex bundles ξ and η is a complex bundle, and so is the induced bundle $f^*\xi$. The principal bundle $F(\xi)$ of frames is now a principal bundle with group $\mathrm{GL}(n, \mathbb{C}) =$ the set of all non-singular $n \times n$ matrices with complex entries (which may be identified in a natural way with the set of all non-singular linear transformations of \mathbb{C}^n). Note that the Covering Homotopy Theorem (Theorem 4) holds for complex

bundles, since it holds for the corresponding principal bundles. There are two reasons for discussing complex bundles, and their characteristic classes. On the one hand, everything works out to be simpler; on the other hand, there are relations between the characteristic classes for real bundles and those for complex bundles. To discuss complex bundles, however, we need several preliminaries about complex vector spaces.

On the vector space \mathbb{C}^n we could consider the bilinear function

$$(z, w) \mapsto \sum_{i=1}^n z^i w^i.$$

This is not an inner product, since it is not even real, and certainly not positive definite. The linear transformations $T: \mathbb{C}^n \rightarrow \mathbb{C}^n$ which preserve this bilinear function correspond to $n \times n$ complex matrices A such that $AA^t = I$. This group of matrices is known as the **complex orthogonal group**. It is of little interest to us, mainly because it is not compact. We consider instead the function $\mathbb{C}^n \times \mathbb{C}^n \rightarrow \mathbb{C}$ given by

$$\langle z, w \rangle = \sum_{i=1}^n z^i \cdot \overline{w^i}.$$

More generally, for any vector space V over \mathbb{C} we define an **Hermitian inner product** to be a map $\langle \cdot, \cdot \rangle: V \times V \rightarrow \mathbb{C}$ which is linear over \mathbb{C} in the first variable, and which satisfies

$$\begin{aligned} \langle v, w \rangle &= \overline{\langle w, v \rangle} & (\implies \langle v, v \rangle \text{ is real}) \\ \langle v, v \rangle &> 0 & \text{for } v \neq 0. \end{aligned}$$

The first condition shows that $\langle \cdot, \cdot \rangle$ is conjugate linear in the second variable (i.e., $\langle v, w_1 + w_2 \rangle = \langle v, w_1 \rangle + \langle v, w_2 \rangle$ and $\langle v, \alpha w \rangle = \bar{\alpha} \langle v, w \rangle$). Because of the second condition, we can define $|v| = \sqrt{\langle v, v \rangle}$. We compute that

$$\begin{aligned} |v + w|^2 - |v - w|^2 &= 2(\langle v, w \rangle + \overline{\langle v, w \rangle}) \\ \implies |v - iw|^2 - |v + iw|^2 &= 2i(\langle v, w \rangle - \overline{\langle v, w \rangle}). \end{aligned}$$

Consequently, we can express $\langle v, w \rangle$ in terms of $|\cdot|$. A basis v_1, \dots, v_n of V is **orthonormal** with respect to an Hermitian inner product $\langle \cdot, \cdot \rangle$ if we have, precisely as in the real case, $\langle v_i, v_j \rangle = \delta_{ij}$. We can always obtain an orthonormal basis from a given one by the Gram-Schmidt process, which works just as well for Hermitian inner products. Hence, any n -dimensional Hermitian inner product

space $(V, \langle \cdot, \cdot \rangle)$ is isomorphic to \mathbb{C}^n with the standard Hermitian inner product $\langle z, w \rangle = \sum_i z^i \cdot \overline{w^i}$.

We define $U(n) \subset GL(n, \mathbb{C})$ to be the subgroup of all A such that $AA^* = I$, where A^* denotes the conjugate transpose of A ,

$$A^* = \overline{A}^t, \quad \text{i.e.,} \quad A^*_{ij} = \overline{A_{ji}}.$$

We can also think of $U(n)$ as the set of all linear transformations of \mathbb{C}^n which preserve the standard Hermitian inner product. It is easy to see that $U(n)$ is compact, just like $O(n)$. Thus $U(n)$ must be a Lie group (Theorem I.10-15). To see this in a more elementary way, we can consider the exponential map $\exp: (n \times n \text{ complex matrices}) \rightarrow GL(n, \mathbb{C})$ defined, just as in the real case, by

$$\exp M = I + M + \frac{M^2}{2!} + \cdots.$$

Reasoning as on pg. I.388, we easily see that $U(n)$ is a Lie group whose Lie algebra $\mathfrak{u}(n)$ is the set of all $n \times n$ complex matrices M with $M + M^* = 0$ (skew-Hermitian M). Thus $M \in \mathfrak{u}(n)$ if and only if M has the form

$$\begin{pmatrix} ib_{11} & & -B^* \\ & \ddots & \\ B & & ib_{nn} \end{pmatrix} \quad b_{ii} \text{ real.}$$

So $U(n)$ has dimension

$$n + 2(1 + \cdots + n - 1) = n^2.$$

Notice that $U(1)$ is just the set of complex numbers of absolute value 1. Hence $U(1)$ is connected. We can regard $S^{2n-1} \subset \mathbb{C}^n$ as the set of all $z \in \mathbb{C}^n$ with $|z| = 1$. So for $n \geq 2$ we can define $f: U(n) \rightarrow S^{2n-1}$ by $f(A) = A(p_0)$, where p_0 is the n -tuple of complex numbers $(0, \dots, 0, 1)$. Then $f^{-1}(p_0)$ is homeomorphic to $U(n-1)$. Using induction, as in Problem I.3-30, we see that $U(n)$ is connected for all n . (Reasoning similar to that in Problem I.3-31 would show that $GL(n, \mathbb{C})$ is also connected.)

Every vector space V over \mathbb{C} is also a vector space $V_{\mathbb{R}}$ over \mathbb{R} [formally, $V_{\mathbb{R}}$ is V with the same addition map $V \times V \rightarrow V$ and the multiplication $\mathbb{R} \times V \rightarrow V$ which is the restriction of the given multiplication $\mathbb{C} \times V \rightarrow V$]. If v_1, \dots, v_n is a basis for V over \mathbb{C} , then $v_1, iv_1, v_2, iv_2, \dots, v_n, iv_n$ is a basis for $V_{\mathbb{R}}$ over \mathbb{R} . Let $T: V \rightarrow V$ be a linear transformation (over \mathbb{C}) whose matrix with respect to v_1, \dots, v_n is the $n \times n$ complex matrix

$$A = (\alpha_{jk}) = (a_{jk} + ib_{jk}),$$

so that

$$Tv_j = \sum_{k=1}^n \alpha_{kj} v_k.$$

Then the matrix of $T: V_{\mathbb{R}} \rightarrow V_{\mathbb{R}}$ with respect to the basis $v_1, iv_1, \dots, v_n, iv_n$ is the $2n \times 2n$ real matrix $h(A) = (\tilde{\alpha}_{jk})$, where $\tilde{\alpha}_{jk}$ is the 2×2 block

$$\tilde{\alpha}_{jk} = \begin{pmatrix} a_{jk} & -b_{jk} \\ b_{jk} & a_{jk} \end{pmatrix}.$$

It is easy to see, using block multiplication of matrices, that

$$h: \{n \times n \text{ complex matrices}\} \rightarrow \{2n \times 2n \text{ real matrices}\}$$

is a homomorphism. Hence it also gives us a homomorphism

$$h: \text{GL}(n, \mathbb{C}) \rightarrow \text{GL}(2n, \mathbb{R}),$$

and moreover, we easily see that

$$h_* = h: \mathfrak{gl}(n, \mathbb{C}) \rightarrow \mathfrak{gl}(2n, \mathbb{R}).$$

It is also easy to see that

$$h: \text{U}(n) \rightarrow \text{O}(2n).$$

Since $\text{U}(n)$ is connected, and h takes the identity matrix of $\text{U}(n)$ to the identity matrix of $\text{O}(2n)$, we actually have

$$h: \text{U}(n) \rightarrow \text{SO}(2n).$$

This also follows from

48. PROPOSITION. For every $n \times n$ complex matrix A we have

$$\det h(A) = |\det A|^2.$$

PROOF. The formula clearly holds for a diagonal matrix

$$A = \begin{pmatrix} a_{11} + ib_{11} & & 0 \\ & \ddots & \\ 0 & & a_{nn} + ib_{nn} \end{pmatrix} \Rightarrow h(A) = \begin{pmatrix} a_{11} & -b_{11} & & 0 \\ b_{11} & a_{11} & & \\ & & \ddots & \\ 0 & & & a_{nn} & -b_{nn} \\ & & & b_{nn} & a_{nn} \end{pmatrix}.$$

So it also holds for diagonalizable matrices. But the diagonalizable matrices are dense, and both sides of the equation are continuous in A . So it holds for all A . ♦

If v_1, \dots, v_n and w_1, \dots, w_n are two bases of V and A is the matrix expressing the w 's in terms of the v 's, then $h(A)$ is the matrix expressing the basis $w_1, iw_1, \dots, w_n, iw_n$ in terms of $v_1, iv_1, \dots, v_n, iv_n$. Since $\det h(A) > 0$, this shows that $V_{\mathbb{R}}$ has a natural orientation (which is but a reflection of the fact that $\mathrm{GL}(n, \mathbb{C})$ is connected). If ξ is a complex vector bundle, then we can form a real vector bundle $\xi_{\mathbb{R}}$ by replacing each fibre by the corresponding vector space over \mathbb{R} ; clearly $\xi_{\mathbb{R}}$ is always orientable, with a natural orientation.

For complex vector bundles it is natural to consider **Hermitian metrics**, which assign an Hermitian inner product to each fibre. We can prove they exist, as in the real case, by using partitions of unity (note that a positive real multiple of an Hermitian inner product is also an Hermitian inner product). Using an Hermitian inner product $\langle \cdot, \cdot \rangle$ on the complex bundle $\xi = \pi: E \rightarrow X$ we can define the principal bundle $U(\xi) = \varpi: U(E) \rightarrow X$ with group $U(n)$, whose fibre $\varpi^{-1}(x)$ is the set of all frames of $\pi^{-1}(x)$ which are orthonormal with respect to $\langle \cdot, \cdot \rangle$.

Corresponding to the Grassmannian $G_n(\mathbb{R}^N)$, we have the **complex Grassmannian manifold** $G_n(\mathbb{C}^N)$, consisting of all $W \subset \mathbb{C}^N$ which are subspaces of \mathbb{C}^N (as a vector space over \mathbb{C}) of complex dimension n . If $V_n(\mathbb{C}^N)$ is the set of all linearly independent n -tuples $(v_1, \dots, v_n) \in \mathbb{C}^N \times \dots \times \mathbb{C}^N$, we define the map

$$\rho: V_n(\mathbb{C}^N) \rightarrow G_n(\mathbb{C}^N)$$

by letting

$$\rho((v_1, \dots, v_n)) = (\text{complex}) \text{ subspace of } \mathbb{C}^N \text{ spanned by } v_1, \dots, v_n,$$

and we give $G_n(\mathbb{C}^N)$ the quotient topology for this map. Reasoning exactly as in the real case, we see that $G_n(\mathbb{C}^N)$ can also be described as the left coset space

$$U(N)/U(n) \times U(N-n).$$

Over $G_n(\mathbb{C}^N)$ we have a natural complex bundle $\gamma^n(\mathbb{C}^N)$ defined exactly as in the real case, and for $M > N$ there is a natural map $\alpha: G_n(\mathbb{C}^N) \rightarrow G_n(\mathbb{C}^M)$ such that $\gamma^n(\mathbb{C}^N) \simeq \alpha^* \gamma^n(\mathbb{C}^M)$. The reader may easily check that Theorems 6 and 7 hold for complex bundles when we replace $\gamma^n(\mathbb{R}^N)$ by $\gamma^n(\mathbb{C}^N)$ throughout; the proofs are exactly the same.

To find the characteristic classes for complex bundles, we thus need to compute the cohomology of $U(N)/U(n) \times U(N-n)$. For this we need the solution to two invariance problems. First we want to consider polynomial functions on $\mathbb{C}^n \times \dots \times \mathbb{C}^n$, by which we mean real-valued functions which are polynomials (over \mathbb{R}) in the real and imaginary components of the various vectors.

49. THEOREM. Every polynomial function f of m vectors in \mathbb{C}^n which is invariant under $U(n)$ can be written as a polynomial in the real and imaginary parts of the Hermitian inner products.

Notice that this result is much simpler than the corresponding result for $O(n)$ and $SO(n)$, for there are no determinants involved, even though $U(n)$ is connected. The proof is also simpler, in the sense that various delicate details which arose in the proof of Theorem 35 are not needed. However, certain other considerations are required, and the proof is deferred to Addendum 1.

Another instance of the greater simplicity to be found in the complex domain is afforded by the spectral theorem, which is both more general and easier to prove. We recall that for every linear transformation $T: \mathbb{C}^n \rightarrow \mathbb{C}^n$ there is a unique linear transformation $T^*: \mathbb{C}^n \rightarrow \mathbb{C}^n$, the **adjoint** of T , with

$$\langle Tv, w \rangle = \langle v, T^*w \rangle \quad \text{for } v, w \in \mathbb{C}^n.$$

If T corresponds to the matrix A , then T^* corresponds to the conjugate transpose matrix A^* . We call A **normal** if $AA^* = A^*A$, and similarly for transformations. Both self-adjoint transformations ($T^* = T$) and skew-adjoint transformations ($T^* = -T$) are normal. If T is normal, then

$$\langle Tv, Tv \rangle = \langle v, T^*Tv \rangle = \langle v, TT^*v \rangle = \langle T^*v, T^*v \rangle.$$

Applying this to $T - \lambda I$, which is also normal, we see that

$$|(T - \lambda I)v| = |(T^* - \bar{\lambda} I)v|.$$

Now any linear transformation $T: \mathbb{C}^n \rightarrow \mathbb{C}^n$ has an eigenvector, since the equation $\det(T - \lambda I) = 0$ has a root in the field \mathbb{C} . The above equation shows that if T is normal, then an eigenvector v of T is also an eigenvector of T^* . Therefore the subspace $[v]$ spanned by v is invariant under T^* . Consequently, the orthogonal complement $[v]^\perp$ (under the Hermitian inner product) is invariant under $T^{**} = T$. From the invariance of both $[v]$ and $[v]^\perp$ under T , we easily see, by induction, that T has an orthonormal basis of eigenvectors. Equivalently, for every normal matrix A , there is a matrix $B \in U(n)$ such that BAB^{-1} is a diagonal matrix.

Now it is easy to give a canonical form for elements of $\mathfrak{u}(n)$.

50. PROPOSITION. For every $A \in \mathfrak{u}(n)$ there is a matrix $B \in U(n)$ such that

$$BAB^{-1} = \begin{pmatrix} i\lambda_1 & & 0 \\ & \ddots & \\ 0 & & i\lambda_n \end{pmatrix} \quad \lambda_j \text{ real.}$$

PROOF. Since $A = -A^*$ is normal, there is $B \in U(n)$ such that BAB^{-1} is diagonal. Moreover,

$$(BAB^{-1})^* = B^{-1*}A^*B^* = BA^*B^{-1} = -BAB^{-1},$$

so the diagonal entries of $B^{-1}AB$ must be pure imaginary. ♦

Using this result, we can easily describe the polynomial functions on $\mathfrak{u}(n)$ which are invariant under the adjoint action of $U(n)$. Since the polynomials f_1, \dots, f_n of section 8 are not real-valued on $\mathfrak{u}(n)$, it is convenient to consider instead the polynomials

$$\tilde{f}_k(M) = i^k f_k(M) = f_k(iM),$$

so that

$$\det(I + \lambda iM) = 1 + \lambda \tilde{f}_1(M) + \dots + \lambda^n \tilde{f}_n(M).$$

We also set $f_0(M) = 1$. If $M \in \mathfrak{u}(n)$, then for all real λ we have

$$(I + \lambda iM)^* = I + \lambda iM \implies \overline{\det(I + \lambda iM)} = \det(I + \lambda iM),$$

which shows that all $\tilde{f}_i(M)$ are real. It is easy to see, as on page 337, that for all $A \in \mathfrak{gl}(r, \mathbb{C})$ and $B \in \mathfrak{gl}(s, \mathbb{C})$ we have

$$\tilde{f}_k(A \oplus B) = \sum_{l=0}^k \tilde{f}_l(A) \cdot \tilde{f}_{k-l}(B).$$

51. THEOREM. Every polynomial function f on $\mathfrak{u}(n)$ which is invariant under the adjoint action of $U(n)$ is a polynomial in $\tilde{f}_1, \dots, \tilde{f}_n$.

PROOF. For $\lambda_1, \dots, \lambda_n \in \mathbb{C}$, let $[\lambda_1, \dots, \lambda_n]$ be the diagonal matrix with entries $i\lambda_1, \dots, i\lambda_n$ on the diagonal. Define

$$g(\lambda_1, \dots, \lambda_n) = f([\lambda_1, \dots, \lambda_n]).$$

Then g is a polynomial in $\lambda_1, \dots, \lambda_n$. Moreover, g is symmetric, since

$$[\lambda_{\pi(1)}, \dots, \lambda_{\pi(n)}] = A \cdot [\lambda_1, \dots, \lambda_n] A^{-1}$$

where $A \in U(n)$ is a suitable permutation matrix. So we can write

$$g(\lambda_1, \dots, \lambda_n) = p(\sigma_1(i\lambda_1, \dots, i\lambda_n), \dots, \sigma_n(i\lambda_1, \dots, i\lambda_n))$$

for some polynomial p . Then

$$f([\lambda_1, \dots, \lambda_n]) = p(\tilde{f}_1([\lambda_1, \dots, \lambda_n]), \dots, \tilde{f}_n([\lambda_1, \dots, \lambda_n])).$$

The result follows as before, using Proposition 50. ♦

Using Theorems 49 and 51, we can carry out the whole program of section 9 for

$$G_n(\mathbb{C}^N) = \mathrm{U}(N)/\mathrm{U}(n) \times \mathrm{U}(N-n) = \mathrm{U}(N)/H.$$

A bi-invariant Riemannian metric $\langle \cdot, \cdot \rangle$ on $\mathrm{U}(n)$ can be defined explicitly as follows. For $M, P \in \mathfrak{u}(n)$, let

$$\langle M, P \rangle = \mathrm{Re}(\mathrm{trace} \, MP^*) = \mathrm{Re} \sum_{i,j} M_{ij} \cdot \overline{P_{ij}}.$$

As in the case of $\mathrm{O}(n)$, if we extend $\langle \cdot, \cdot \rangle$ to $\mathrm{U}(n)$ by left invariance, then it will also be right invariant. Now \mathfrak{h}^\perp consists of all matrices

$$\begin{pmatrix} 0 & P \\ -P^* & 0 \end{pmatrix} \quad P \text{ an } n \times (N-n) \text{ complex matrix.}$$

On $\mathfrak{h}^\perp \times \mathfrak{h}^\perp$ we have the functions

$$(P, Q) \mapsto \sum_r P_i^r \cdot \overline{Q_j^r}$$

(which are bilinear *over* \mathbb{R}); their alternations ψ_{ij} , given by

$$\psi_{ij}(P, Q) = \sum_r P_i^r \cdot \overline{Q_j^r} - Q_i^r \cdot \overline{P_j^r},$$

are complex-valued alternating bilinear functions on \mathfrak{h}^\perp . A form $\eta \in \Omega^k(\mathfrak{h}^\perp)$ will be invariant under $\{I\} \times \mathrm{U}(N-n)$ if and only if it is a linear combination of wedge products of the forms $\mathrm{Re} \, \psi_{ij}$ and $\mathrm{Im} \, \psi_{ij}$ (since there are no determinants to worry about in the first main theorem of invariance theory for $\mathrm{U}(n)$, we do not need $k < N-n$). Such linear combinations can be described as $f(\psi)$ for polynomial functions $f: \mathfrak{u}(n) \rightarrow \mathbb{R}$ [this representation is unique in dimensions $< N-n$], and the combinations which are invariant under $\mathrm{U}(n) \times \{I\}$ correspond to functions $f: \mathfrak{u}(n) \rightarrow \mathbb{R}$ which are invariant under the adjoint action of $\mathrm{U}(n)$. Thus we have a class $\tilde{f}_i(\psi) \in H^{2i}(G_n(\mathbb{C}^N))$ for each of the polynomials $\tilde{f}_1, \dots, \tilde{f}_n$ of Theorem 51, and every element of $H^*(\mathrm{U}(N)/\mathrm{U}(n) \times \mathrm{U}(N-n))$ is a linear combination of cup products of these elements [it is a *unique* linear combination in dimensions $< N-n$].

The analogue of Proposition 41 holds, so we will consider only N with $2n < N-n$. Then all elements of $H^*(G_n(\mathbb{C}^N))$ in dimensions $< N-n$ are unique linear combinations of cup products of the classes corresponding to

$$\tilde{f}_1(\psi), \dots, \tilde{f}_n(\psi).$$

We let

$$c_{n;k} \in H^{2k}(G_n(\mathbb{C}^N)) \quad k = 1, \dots, n$$

be the class corresponding to

$$\frac{1}{(2\pi)^k} \tilde{f}_k(\psi).$$

For an n -dimensional complex bundle ξ over M we define

$$c_k(\xi) = g^* c_{n;k},$$

where

$$g: M \rightarrow G_n(\mathbb{C}^N) \quad \text{satisfies} \quad g^* \gamma^n(\mathbb{C}^N) \simeq \xi.$$

The characteristic class $\xi \mapsto c_k(\xi)$ is called the k^{th} **Chern class** for n -dimensional complex bundles; every characteristic class for n -dimensional complex bundles is a polynomial in the Chern classes c_1, \dots, c_n . The class

$$c(\xi) = 1 + c_1(\xi) + \dots + c_n(\xi) = c_0(\xi) + c_1(\xi) + \dots + c_n(\xi)$$

is called the **total Chern class** of the n -dimensional complex bundle ξ .

Just as in the real case, the Chern classes of an n -dimensional complex bundle $\xi = \pi: E \rightarrow M$ may be described in terms of a connection. Choose any Hermitian metric for ξ , form the corresponding principal $U(n)$ bundle $U(\xi) = \varpi: U(E) \rightarrow M$, and let ω be a $\mathfrak{u}(n)$ -valued connection on $U(\xi)$, with $\mathfrak{u}(n)$ -valued curvature form Ω .

52. THEOREM. The k^{th} Chern class $c_k(\xi)$ of ξ is represented by the unique form Λ on M with

$$\varpi^* \Lambda = \frac{1}{(2\pi)^k} \tilde{f}_k(\Omega).$$

In other words, we have

$$c_k(\xi) = w(g_k),$$

where $g_k = \mathcal{J}(\tilde{f}_k) \in I^{2k}(U(n))$ corresponds to the polynomial function \tilde{f}_k on $\mathfrak{u}(n)$, and w is the Weil homomorphism for $U(\xi)$.

PROOF. First of all, an obvious analogue of Corollary 5 shows that the principal bundles η are all equivalent, no matter what Hermitian metric we choose. Now to prove the result, we just have to consider the universal bundle $\gamma^n(\mathbb{C}^N)$. This has a natural Hermitian metric, just like the natural Riemannian metric for $\tilde{\gamma}^n(\mathbb{R}^N)$, on page 345. All the succeeding considerations also have natural analogues, and the result follows exactly as in the proof of Theorem 42 (or Theorem 43). ♦

As an immediate consequence we have

53. THEOREM. If ξ and η are complex bundles over M , then the total Chern class of $\xi \oplus \eta$ is given by the **Whitney product formula**

$$c(\xi \oplus \eta) = c(\xi) \cup c(\eta).$$

PROOF. Exactly like the proof of Theorem 45, except now using the formula on page 362. ♦

We can also find relationships between Chern classes and Pontryagin classes. For a real vector space V , we define a complex vector space $V_{\mathbb{C}}$ by letting $V_{\mathbb{C}} = V \oplus V$, with complex multiplication determined by

$$i \cdot (v, w) = (-w, v) \quad [\text{thus we think of } (v, w) \text{ as } v + iw].$$

Doing this in each fibre of a real vector bundle ξ gives a complex vector bundle $\xi_{\mathbb{C}}$.

54. THEOREM. If $\xi = \pi: E \rightarrow M$ is an oriented n -dimensional vector bundle, then

$$c_{2k}(\xi_{\mathbb{C}}) = (-1)^k p_k(\xi) \quad k = 1, \dots, [n/2].$$

PROOF. Choose the Hermitian metric on $\xi_{\mathbb{C}} = \pi': E_{\mathbb{C}} \rightarrow M$ to be an extension of a Riemannian metric on ξ . Then $\text{SO}(E) \subset \text{U}(E_{\mathbb{C}})$, and the projection $\varpi: \text{SO}(E) \rightarrow M$ is the restriction of the projection $\varpi': \text{U}(E_{\mathbb{C}}) \rightarrow M$. A connection ω on $\text{SO}(E)$ has a unique extension to a $(\mathfrak{u}(n))$ -valued connection ψ on $\text{U}(E_{\mathbb{C}})$ [as in the proof of Theorem 22, ψ is determined on the new vertical vectors of $\text{SO}(E)$, and hence on all of $\text{U}(E_{\mathbb{C}})$]. Let Ψ be the curvature form of ψ . At any point $e \in \text{SO}(E)$ the horizontal vectors for ψ are the same as for ω , so at e we have

$$\begin{aligned} \Psi &= \Omega \quad [\text{on tangent vectors to } \text{SO}(E)] \\ \implies \tilde{f}_{2k}(\Psi) &= \tilde{f}_{2k}(\Omega) = (-1)^k f_{2k}(\Omega). \end{aligned}$$

So if Λ represents $p_k(\xi)$ and Υ represents $c_{2k}(\xi_{\mathbb{C}})$, then at e we have

$$\begin{aligned} \varpi^* \Lambda &= \frac{1}{(2\pi)^k} f_{2k}(\Omega) \\ &= (-1)^k \frac{1}{(2\pi)^k} \tilde{f}_{2k}(\Psi) \\ &= (-1)^k \varpi'^* \Upsilon. \end{aligned}$$

This implies that

$$\Lambda = (-1)^k \Upsilon. \quad \spadesuit$$

The odd Chern classes, which are missing in Theorem 54, are easily calculated by the following considerations. Every complex vector space V gives rise to another complex vector space \bar{V} in which complex multiplication \bullet is defined by

$$\alpha \bullet v = \bar{\alpha} \cdot v.$$

Applying this process to each fibre of a complex bundle ξ we get the **conjugate bundle** $\bar{\xi}$. The bundles ξ and $\bar{\xi}$ are equivalent as real bundles, of course, but there may not be an equivalence which is complex linear on each fibre.

55. PROPOSITION. If ξ is a complex vector bundle, then

$$c(\bar{\xi}) = 1 - c_1(\xi) + c_2(\xi) - c_3(\xi) + \cdots.$$

PROOF. If $\varpi: U(E) \rightarrow M$ is the associated principal bundle $U(\xi)$ for ξ , with R_A the right multiplication by $A \in U(n)$, then for the principal bundle $U(\bar{\xi})$ we may choose the same total space $U(E)$, but with the action \bar{R} of $U(n)$ on the right given by

$$\bar{R}_A = R_{\bar{A}}.$$

So if ω is a connection on $U(\xi)$, with curvature form Ω , then $\bar{\omega}$ (the complex conjugate of ω) will be a connection on $U(\bar{\xi})$, with curvature form $\bar{\Omega}$. If Λ represents $c_k(\xi)$ and Υ represents $c_k(\bar{\xi})$, then

$$\begin{aligned} \varpi^* \Upsilon &= \frac{1}{(2\pi)^k} \tilde{f}_k(\bar{\Omega}) \\ &= \frac{1}{(2\pi)^k} \tilde{f}_k(-\Omega^t) \\ &= \frac{(-1)^k}{(2\pi)^k} \tilde{f}_k(\Omega) \\ &= (-1)^k \varpi^* \Lambda. \end{aligned}$$

Hence $\Upsilon = (-1)^k \Lambda. \quad \spadesuit$

56. COROLLARY. If ξ is a real vector bundle, then

$$c_k(\xi_{\mathbb{C}}) = 0 \quad \text{for } k \text{ odd.}$$

PROOF. We just have to note that

$$\xi_{\mathbb{C}} \simeq \bar{\xi}_{\mathbb{C}} \quad (\text{as complex bundles}).$$

This is due to the fact that there is a natural complex isomorphism $V_{\mathbb{C}} \rightarrow \bar{V}_{\mathbb{C}}$ for every real vector space V —we merely take $(v, w) \mapsto (v, -w)$. ♦

Instead of starting with a real bundle, we can instead begin with a complex bundle ξ , and regard it as an oriented real bundle $\xi_{\mathbb{R}}$ (of even dimension). In order to find its Pontryagin and Euler classes, we need a lemma concerning the homomorphism $h: \mathrm{GL}(n, \mathbb{C}) \rightarrow \mathrm{GL}(2n, \mathbb{R})$ defined on page 359. Since $h = h_*: \mathfrak{gl}(n, \mathbb{C}) \rightarrow \mathfrak{gl}(2n, \mathbb{R})$, we have $h(\mathfrak{u}(n)) \subset \mathfrak{o}(2n)$.

57. LEMMA. For $M \in \mathfrak{u}(n)$ we have

$$f_{2k}(h(M)) = (-1)^k \sum_{l=0}^{2k} (-1)^l \tilde{f}_l(M) \tilde{f}_{2k-l}(M),$$

$$\mathrm{Pf}(h(M)) = \tilde{f}_n(M).$$

PROOF. For all real λ we have

$$\begin{aligned} 1 + \lambda^2 f_2(h(M)) + \cdots + \lambda^{2n} f_{2n}(h(M)) &= \det(I_{2n} + \lambda h(M)) & I_{2n} &= \text{identity of } \mathrm{O}(2n) \\ &= \det h(I_n + \lambda M) & I_n &= \text{identity of } \mathrm{U}(n) \\ &= |\det(I_n + \lambda M)|^2 & & \text{by Proposition 48} \\ &= |1 - i\lambda \tilde{f}_1(M) - \lambda^2 \tilde{f}_2(M) + i\lambda^3 \tilde{f}_3(M) + \lambda^4 \tilde{f}_4(M) - \cdots|^2 \\ &= |(1 - \lambda^2 \tilde{f}_2(M) + \lambda^4 \tilde{f}_4(M) - \cdots) - i(\lambda \tilde{f}_1(M) - \lambda^3 \tilde{f}_3(M) + \cdots)|^2 \\ &= (1 - \lambda^2 \tilde{f}_2(M) + \lambda^4 \tilde{f}_4(M) - \cdots)^2 + (\lambda \tilde{f}_1(M) - \lambda^3 \tilde{f}_3(M) + \cdots)^2. \end{aligned}$$

The coefficient of λ^{2k} on the right side is

$$\begin{aligned} &\sum_{l \text{ even}} (-1)^{\frac{l}{2}} (-1)^{\frac{2k-l}{2}} \tilde{f}_l(M) \tilde{f}_{2k-l}(M) \\ &\quad + \sum_{l \text{ odd}} (-1)^{\frac{l-1}{2}} (-1)^{\frac{2k-l-1}{2}} \tilde{f}_l(M) \tilde{f}_{2k-l}(M) \\ &= (-1)^k \left[\sum_{l \text{ even}} \tilde{f}_l(M) \tilde{f}_{2k-l}(M) - \sum_{l \text{ odd}} \tilde{f}_l(M) \tilde{f}_{2k-l}(M) \right] \\ &= (-1)^k \sum_l (-1)^l \tilde{f}_l(M) \tilde{f}_{2k-l}(M). \end{aligned}$$

For the Pfaffian we have

$$\begin{aligned} [\text{Pf}(h(M))]^2 &= \det h(M) = |\det M|^2 = |f_n(M)|^2 \\ &= \left| \frac{\tilde{f}_n(M)}{i^n} \right|^2 = |\tilde{f}_n(M)|^2, \end{aligned}$$

and hence

$$\text{Pf}(h(M)) = \pm \tilde{f}_n(M).$$

To settle the sign, we consider

$$M = \begin{pmatrix} i & & 0 \\ & \ddots & \\ 0 & & i \end{pmatrix} \Rightarrow h(M) = \begin{pmatrix} -S & & 0 \\ & \ddots & \\ 0 & & -S \end{pmatrix} \quad S = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

Then

$$\text{Pf}(h(M)) = (-1)^n = \det iM = \tilde{f}_n(M),$$

so the + sign is correct. ♦

The relevance of this Lemma will become immediately apparent in the proof of our final result.

58. THEOREM. If ξ is a complex bundle of dimension n , then

$$p_k(\xi_{\mathbb{R}}) = (-1)^k \sum_{l=0}^{2k} (-1)^l c_l(\xi) \cup c_{2k-l}(\xi) \quad k = 1, \dots, 2n,$$

and

$$\chi(\xi_{\mathbb{R}}) = c_n(\xi).$$

PROOF. Note that an Hermitian inner product $\langle \cdot, \cdot \rangle$ on a complex vector space V gives an ordinary inner product on $V_{\mathbb{R}}$ —we define $v_1, iv_1, \dots, v_n, iv_n$ to be orthonormal whenever v_1, \dots, v_n is orthonormal with respect to $\langle \cdot, \cdot \rangle$. This inner product on $V_{\mathbb{R}}$ is well-defined, for if $w_j = \sum_l a_{lj} v_l$ is another orthonormal basis, then the matrix $A = (a_{lj})$ is clearly in $U(n)$, so $h(A) \in SO(n)$. Choosing an Hermitian metric on $\xi = \pi: E \rightarrow M$, and applying this construction to each fibre, we obtain a Riemannian metric on $\xi_{\mathbb{R}}$. Moreover, for the corresponding principal bundles, we have $U(E) \subset SO(E)$, and the projection $\varpi: U(E) \rightarrow M$ is the restriction of the projection $\varpi': SO(E) \rightarrow M$.

For $A \in U(n)$, the right action R_A on $U(E)$ is just the restriction of the right action $R_{h(A)}$ on $SO(E)$. A connection ω on $U(E)$ is $u(n)$ -valued, as is its curvature form Ω . The $h(u(n))$ -valued form $h \circ \omega$ has a unique extension to a connection ψ on $SO(E)$, with curvature form Ψ . At any point $e \in U(E)$ we have

$$\Psi = h \circ \Omega \quad \text{on tangent vectors to } U(E).$$

So if Λ represents $p_k(\xi_{\mathbb{R}})$ and Λ_l represents $c_l(\xi)$ for $l = 0, \dots, 2k$, then at e we have

$$\begin{aligned} \varpi'^* \Lambda &= \frac{1}{(2\pi)^{2k}} f_{2k}(\Psi) \\ &= \frac{1}{(2\pi)^{2k}} f_{2k}(h \circ \Omega) \\ &= \frac{1}{(2\pi)^{2k}} (-1)^k \sum_{l=0}^{2k} (-1)^l \tilde{f}_l(\Omega) \wedge \tilde{f}_{2k-l}(\Omega) \quad \text{by Lemma 57} \\ &= (-1)^k \sum_{l=0}^{2k} (-1)^l \varpi^* \Lambda_l \wedge \varpi^* \Lambda_{2k-l}, \end{aligned}$$

which proves the first formula.

If Λ represents $\chi(\xi_{\mathbb{R}})$, then at e we have

$$\begin{aligned} \varpi'^* \Lambda &= \frac{1}{(2\pi)^n} \text{Pf}(\Psi) \\ &= \frac{1}{(2\pi)^n} \text{Pf}(h \circ \Omega) \\ &= \frac{1}{(2\pi)^n} \tilde{f}_n(\Omega) \quad \text{by Lemma 57} \\ &= \varpi^* \Lambda_n. \end{aligned}$$

This proves the second formula. ♦

12. VALEDICTORY

Now that we have built up so much machinery, it seems a shame not to use it. But this would really take us out of the field of differential geometry entirely. We have tried to show how the characteristic classes arise naturally, how they can be computed by differential geometric means, why they should be

expressible in terms of curvature, and especially how the Euler class is expressed in terms of $K_n dV$, which involves $\text{Pf}(\Omega)$. For further applications of these characteristic classes, the reader is urged to consult books specifically devoted to the subject, where characteristic classes are usually defined by methods of algebraic topology. One of the most famous set of notes, now finally available in book form, is Milnor and Stasheff [1]. Here the Euler class is defined essentially as we have defined it, in terms of the Thom class. But the Pontryagin and Chern classes are defined in completely different ways. For a complex n -dimensional bundle $\xi = \pi: E \rightarrow X$, the top Chern class $c_n(\xi)$ is *defined* by the formula of Theorem 58, as

$$c_n(\xi) = \chi(\xi_{\mathbb{R}}).$$

The other Chern classes are defined inductively, as follows. Choosing an Hermitian metric for ξ , we form the associated sphere bundle $S \subset E$, and let $\pi_0: S \rightarrow X$ be the restriction of π . It turns out that the map

$$\pi_0^*: H^k(X) \rightarrow H^k(S)$$

is an isomorphism for $k < n$. Now $\pi_0^*\xi$ has a section, so it can be written as the Whitney sum

$$\pi_0^*\xi = \xi_1 \oplus \xi_2,$$

where ξ_2 is a trivial 1-dimensional complex bundle. The Chern class $c_{n-1}(\xi)$ is defined as

$$c_{n-1}(\xi) = (\pi_0^*)^{-1}(c_{n-1}(\xi_1)).$$

This makes sense, since c_{n-1} is defined for the $(n-1)$ -dimensional complex bundle ξ_1 . Moreover, it is compatible with our definition, since it is equivalent to

$$c_{n-1}(\pi_0^*\xi) = c_{n-1}(\xi_1),$$

which is what the Whitney product formula gives when ξ_2 is trivial. Now that $c_{n-1}(\xi)$ is defined for all n -dimensional complex bundles ξ , the Chern class $c_{n-2}(\xi)$ can be defined as

$$c_{n-2}(\xi) = (\pi_0^*)^{-1}(c_{n-1}(\xi_1)),$$

and so on, by induction. After the Chern classes are defined, the Whitney product formula is proved, and the cohomology of $G_n(\mathbb{C}^\infty)$ is calculated, by means of various tricks. The Pontryagin classes are defined by the formula in Theorem 54, and all properties are derived from this definition and the properties of the Chern classes. In the whole development, there is no restriction

to manifolds, and singular homology is used throughout. Moreover, the coefficients are \mathbb{Z} , rather than \mathbb{R} . Integer coefficients can be used because the Thom class can be defined with integer coefficients, so the Euler class has integer coefficients, and the map $\pi_0^*: H^k(X) \rightarrow H^k(S)$ is an isomorphism with integer coefficients. This shows, by the way, that our Euler, Pontryagin, and Chern classes, defined originally with real coefficients, are actually all integral classes; that, of course, was the reason for inserting the various factors $(2\pi)^{-\alpha}$ in the definitions.

ADDENDUM 1

INVARIANT THEORY FOR THE UNITARY GROUP

At first sight, the problem of determining all invariant polynomials for $U(n)$ seems peculiarly complicated, since we are dealing with polynomial functions of the real and imaginary parts of the components of the vectors, rather than polynomial functions of the components themselves. But there is a trick which will allow us to reduce the problem to one where we study only polynomials of the latter type. The basic result which we need for such polynomials can actually be formulated for any field.

Let k be an arbitrary infinite field, and let $V = k^n$ be the standard n -dimensional vector space over k , with standard basis elements e_1, \dots, e_n . The group of all non-singular $n \times n$ matrices with entries in k is denoted by $GL(n, k)$. Just as in the real case, a matrix $A = (a_{ij}) \in GL(n, k)$ is also regarded as a linear transformation $A: V \rightarrow V$, by the rule

$$A(e_i) = \sum_{j=1}^n a_{ji} e_j,$$

so that for a (row vector) $v \in k^n$ we have

$$A(v) = v \cdot A^t.$$

We also define an action of $GL(n, k)$ on the m -fold product $V \times \dots \times V$ by

$$A \cdot (v_1, \dots, v_m) = (A(v_1), \dots, A(v_m)).$$

A function

$$f: V \times \dots \times V \rightarrow k$$

is called a polynomial function if it is a polynomial (over k) in the components of the elements of V ; we also define homogeneous polynomial functions just as before. We say that f is invariant under a group $G \subset GL(n, k)$ if

$$f(A \cdot v) = f(v) \quad \text{for all } v \in V \times \dots \times V, \text{ and all } A \in G.$$

We still have the standard basis vectors e_{ri} for $V \times \dots \times V$, and the partial derivatives $\partial f / \partial e_{ri}$ can be defined formally for polynomial functions f . Euler's theorem can be checked formally, polarizations are defined as before, and the Capelli identities still hold. Introducing the partial ordering on the polynomial functions as before, we still have assertion (A) on page 327.

Actually, we want to be even more general, and consider functions

$$f: \underbrace{V \times \cdots \times V}_m \times \underbrace{V^* \times \cdots \times V^*}_l \rightarrow k.$$

We define an action of $\mathrm{GL}(n, k)$ on $V \times \cdots \times V^*$ by

$$A \cdot (v_1, \dots, v_m, \phi_1, \dots, \phi_l) = (A(v_1), \dots, A(v_m), \phi_1 \circ A^{-1}, \dots, \phi_l \circ A^{-1}),$$

and we say that f is invariant under a group $G \subset \mathrm{GL}(n, k)$ if

$$f(A \cdot (v, \phi)) = f((v, \phi)) \quad \text{for all } (v, \phi) \in V \times \cdots \times V^*, \text{ and } A \in G.$$

For example, the “evaluations”

$$\varepsilon_{rs}(v_1, \dots, v_m, \phi_1, \dots, \phi_l) = \phi_s(v_r)$$

are invariant under all of $\mathrm{GL}(n, k)$. It will be convenient to identify an element $\phi \in V^*$ with the *column* vector

$$\xi = \begin{pmatrix} \phi(e_1) \\ \vdots \\ \phi(e_n) \end{pmatrix}.$$

Then it turns out that the action of $\mathrm{GL}(n, k)$ is

$$A \cdot (v_1, \dots, v_m, \xi_1, \dots, \xi_l) = (v_1 \cdot A^t, \dots, v_m \cdot A^t, (A^{-1})^t \cdot \xi_1, \dots, (A^{-1})^t \cdot \xi_l).$$

We call f a polynomial function if $f(v_1, \dots, v_m, \xi_1, \dots, \xi_l)$ is a polynomial in the v_{ri} and ξ_{sj} (here ξ_{sj} is the entry in the j^{th} row of ξ_s). Notice that the evaluations are polynomial functions—under the identification of V^* with the set of column vectors they are simply the maps

$$\varepsilon_{rs}(v_1, \dots, v_m, \xi_1, \dots, \xi_l) = v_r \cdot \xi_s.$$

Two other important types of polynomial functions are the functions

$$\det_{r_1, \dots, r_n}(v_1, \dots, v_m, \xi_1, \dots, \xi_l) = \det \begin{pmatrix} v_{r_1} \\ \vdots \\ v_{r_n} \end{pmatrix}$$

and

$$\det_{s_1, \dots, s_n}^*(v_1, \dots, v_m, \xi_1, \dots, \xi_l) = \det(\xi_{s_1}, \dots, \xi_{s_n}).$$

They are invariant under the subgroup $\mathrm{SL}(n, k) \subset \mathrm{GL}(n, k)$ consisting of matrices of determinant 1.

We can define homogeneous polynomial functions as before, except now we must consider functions which are homogeneous of degree $(\alpha_1, \dots, \alpha_m)$ in the V variables, and of degree $(\beta_1, \dots, \beta_l)$ in the V^* variables. For any homogeneous f , we can apply the apparatus of the Capelli identities to either the V variables or the V^* variables separately, and obtain assertion (A) on page 327 where the partial ordering $<$ is applied to either the degree in V or the degree in V^* , the polarizations being applied to the variables in V or V^* , respectively.

59. THEOREM. For all m, l , and n we have

$SL_n^{m,l}$: Every polynomial function f of m vectors in k^n and l vectors in $(k^n)^*$ which is invariant under $SL(n, k)$ can be written as a polynomial in the evaluation functions ε_{rs} and the determinant functions \det_{r_1, \dots, r_n} and \det_{s_1, \dots, s_n}^* .

PROOF. The proof is similar to that of Theorem 35, but the steps are easier. First we note that $SL_n^{m,l} \implies SL_n^{m',l'}$ for $m' \leq m$ and $l' \leq l$. Next we have

60. LEMMA. If $SL_n^{n-1, n-1}$ holds, then $SL_n^{m,l}$ holds for all $m \geq n-1, l \geq n-1$.

PROOF. The argument is similar to that for Lemma 36. In the present case we can start with $SL_n^{n-1, n-1}$ rather than $SL_n^{n,n}$ because the term \det appearing in assertion (A) in the case $m = n$ causes no problems—it is one of the invariants in terms of which we are trying to express f . **Q.E.D.**

Now the proof of the special case to which we have reduced the problem does not even require an inductive argument:

61. LEMMA. $SL_n^{n-1, n-1}$ holds for all n .

PROOF. Consider $(v_1, \dots, v_{n-1}, \phi_1, \dots, \phi_{n-1})$ satisfying

$$(*) \quad \det(\phi_i(v_j)) \neq 0.$$

Then $\bigcap_{i=1}^{n-1} \ker \phi_i$ is 1-dimensional. Let $0 \neq w \in \bigcap_i \ker \phi_i$. If we had

$$w = \sum_{j=1}^{n-1} a_j v_j$$

for constants a_i (necessarily not all zero), then we would have

$$0 = \phi_i(w) = \sum_{j=1}^{n-1} a_j \phi_i(v_j) \quad j = 1, \dots, n-1,$$

contradicting (*). So w is linearly independent of v_1, \dots, v_{n-1} . Hence there is some $A \in \text{SL}(n, k)$ such that

$$\begin{aligned} A(e_i) &= v_i \quad i = 1, \dots, n-1 \\ A(e_n) &= \text{a multiple of } w. \end{aligned}$$

Then

$$\begin{aligned} (1) \quad & f(v_1, \dots, v_{n-1}, \phi_1, \dots, \phi_{n-1}) \\ &= f(A^{-1}(v_1), \dots, A^{-1}(v_{n-1}), \phi_1 \circ A, \dots, \phi_{n-1} \circ A) \\ &= f(e_1, \dots, e_{n-1}, \phi_1 \circ A, \dots, \phi_{n-1} \circ A); \end{aligned}$$

note that

$$\begin{aligned} (2) \quad & (\phi_i \circ A)(e_j) = \phi_i(v_j) \quad j = 1, \dots, n-1 \\ & (\phi_i \circ A)(e_n) = 0. \end{aligned}$$

Now define a polynomial function F of $(n-1)^2$ variables a_{ij} , as follows:

$$\begin{aligned} F(\{a_{ij}\}) &= f(e_1, \dots, e_{n-1}, \mu_1, \dots, \mu_{n-1}), \\ &\text{where } \mu_i \text{ are the unique linear functionals with} \\ &\mu_i(e_j) = a_{ij} \quad j = 1, \dots, n-1 \\ &\mu_i(e_n) = 0. \end{aligned}$$

Then equations (1) and (2) show that

$$(**) \quad f(v_1, \dots, v_{n-1}, \phi_1, \dots, \phi_{n-1}) = F(\{\phi_i(v_j)\})$$

whenever (*) holds. A standard argument ("the principle of irrelevance of algebraic inequalities") shows that consequently (**) holds everywhere: for the polynomial

$$[f(v_1, \dots, v_{n-1}, \phi_1, \dots, \phi_{n-1}) - F(\{\phi_i(v_j)\})] \cdot \det(\phi_i(v_j))$$

is identically 0, hence one of the factors must be identically 0, and the second factor certainly isn't. ♦

We will use Theorem 59 only for the case $\mathrm{SL}(n, \mathbb{C})$. We easily see (compare Problem I.10-27) that the Lie algebra $\mathfrak{sl}(n, \mathbb{C})$ of $\mathrm{SL}(n, \mathbb{C})$ consists of all $n \times n$ complex matrices with trace $= 0$. Similarly (compare page 358), the group $\mathrm{SU}(n) = \mathrm{U}(n) \cap \mathrm{SL}(n, \mathbb{C})$ has Lie algebra $\mathfrak{su}(n)$ consisting of all matrices

$$\begin{pmatrix} ib_{11} & & -B^* \\ & \ddots & \\ B & & ib_{nn} \end{pmatrix} \quad \begin{array}{l} b_{ii} \text{ real} \\ \sum b_{ii} = 0. \end{array}$$

Notice that $\mathfrak{su}(n)$ is not a complex subspace of $\mathfrak{gl}(n, \mathbb{C})$; however, it is easy to find the complex subspace $W \subset \mathfrak{gl}(n, \mathbb{C})$ spanned by $\mathfrak{su}(n)$. Note that W must contain

$$-i \cdot \begin{pmatrix} ib_{11} & & 0 \\ & \ddots & \\ 0 & & ib_{nn} \end{pmatrix} = \begin{pmatrix} b_{11} & & 0 \\ & \ddots & \\ 0 & & b_{nn} \end{pmatrix} \quad \begin{array}{l} b_{ii} \text{ real} \\ \sum b_{ii} = 0 \end{array}$$

and

$$-i \cdot \begin{pmatrix} 0 & -(iA)^* \\ & \ddots \\ iA & & 0 \end{pmatrix} = -i \cdot \begin{pmatrix} 0 & +iA^* \\ & \ddots \\ iA & & 0 \end{pmatrix} = \begin{pmatrix} 0 & & A^* \\ & \ddots & \\ A & & 0 \end{pmatrix},$$

and thus also the matrix

$$\begin{pmatrix} 0 & & 0 \\ & \ddots & \\ A & & 0 \end{pmatrix} = \begin{pmatrix} 0 & & -A^* \\ & \ddots & \\ A & & 0 \end{pmatrix} + \begin{pmatrix} 0 & & A^* \\ & \ddots & \\ A & & 0 \end{pmatrix}, \quad \text{as well as} \quad \begin{pmatrix} 0 & & A \\ & \ddots & \\ 0 & & 0 \end{pmatrix}.$$

From this we easily see that

(*) the complex subspace of $\mathfrak{gl}(n, \mathbb{C})$ spanned by $\mathfrak{su}(n)$ is just $\mathfrak{sl}(n, \mathbb{C})$.

This simple fact leads to

62. LEMMA. Let $g: \mathrm{GL}(n, \mathbb{C}) \rightarrow \mathbb{C}$ be a complex analytic function (this makes sense, since $\mathrm{GL}(n, \mathbb{C})$ is an open subset of \mathbb{C}^{n^2}). If g vanishes on $\mathrm{SU}(n)$, then g also vanishes on $\mathrm{SL}(n, \mathbb{C})$.

PROOF. Pick $Y_1, Y_2 \in \mathfrak{su}(n)$, and consider the function $h: \mathbb{C} \rightarrow \mathbb{C}$ defined by

$$h(z) = g(\exp(zY_1 + Y_2)).$$

Then h is analytic and vanishes for all real z . So h vanishes for all z . Similarly, we may now prove that

$$g(\exp(z_1 Y_1 + z_2 Y_2)) = 0 \quad \text{for all } z_1, z_2 \in \mathbb{C}.$$

Then (*) implies that $g(\exp(X)) = 0$ for all $X \in \mathfrak{sl}(n, \mathbb{C})$. But the image of $\exp: \mathfrak{sl}(n, \mathbb{C}) \rightarrow \mathrm{SL}(n, \mathbb{C})$ is dense* in $\mathrm{SL}(n, \mathbb{C})$, since the diagonalizable matrices are certainly in the image of \exp . Hence $g = 0$ on all of $\mathrm{SL}(n, \mathbb{C})$. ♦

63. COROLLARY. Let f be a polynomial function of m vectors of \mathbb{C}^n and l vectors of $(\mathbb{C}^n)^*$ [that is, f is a polynomial over \mathbb{C} in the (complex) components of the vectors]. If f is invariant under $\mathrm{SU}(n)$, then f is also invariant under $\mathrm{SL}(n, \mathbb{C})$, and is thus a polynomial in the evaluation functions ε_{rs} and the determinant functions \det_{r_1, \dots, r_n} and \det_{s_1, \dots, s_n}^* .

PROOF. For fixed $(v, \phi) \in \mathbb{C}^n \times \dots \times (\mathbb{C}^n)^*$, define $g_{(v, \phi)}: \mathrm{GL}(n, \mathbb{C}) \rightarrow \mathbb{C}$ by

$$g_{(v, \phi)}(A) = f(A \cdot (v, \phi)) - f((v, \phi)).$$

Then g is complex analytic, and g vanishes on $\mathrm{SU}(n)$ by hypothesis. So by Lemma 62, g vanishes on $\mathrm{SL}(n, \mathbb{C})$. Since this is true for each (v, ϕ) , it follows that f is invariant under $\mathrm{SL}(n, \mathbb{C})$. ♦

Now we really want to consider \mathbb{R} -valued functions of m vectors in \mathbb{C}^n which are polynomials in the real and imaginary parts of the components of the vectors. Actually, we might as well consider complex-valued functions which are polynomials over \mathbb{C} in the real and imaginary parts of the components of the vectors. Equivalently, we consider functions

$$f: \mathbb{C}^n \times \dots \times \mathbb{C}^n \rightarrow \mathbb{C}$$

which are polynomials over \mathbb{C} in the components v_{ri} of the vectors and in their complex conjugates \bar{v}_{ri} . Given such a function f , we define a function

$$\tilde{f}: \underbrace{\mathbb{C}^n \times \dots \times \mathbb{C}^n}_m \times \underbrace{(\mathbb{C}^n)^* \times \dots \times (\mathbb{C}^n)^*}_m \rightarrow \mathbb{C}$$

as follows:

- (i) if $f(v_1, \dots, v_m) = v_{ri}$, then $\tilde{f}(v_1, \dots, v_m, \xi_1, \dots, \xi_m) = v_{ri}$
- (ii) if $f(v_1, \dots, v_m) = \bar{v}_{ri}$, then $\tilde{f}(v_1, \dots, v_m, \xi_1, \dots, \xi_m) = \xi_{ri}$
- (iii) the correspondence $f \mapsto \tilde{f}$ is an algebra homomorphism.

* Actually, the exponential map is onto $\mathrm{SL}(n, \mathbb{C})$, but we won't prove that here.

Notice that \tilde{f} is a polynomial function in the (complex) components of the vectors of \mathbb{C}^n and $(\mathbb{C}^n)^*$. The mapping $f \mapsto \tilde{f}$ is clearly a one-one correspondence between the polynomials in the v_{ri} and \bar{v}_{ri} , and the polynomials in the v_{ri} and ξ_{ri} . Note that if f is the Hermitian inner product ι_{rs} of v_r and v_s , then \tilde{f} is the evaluation ε_{rs} . If f is the determinant of v_{r_1}, \dots, v_{r_n} , then \tilde{f} is also this determinant; if f is the conjugate of this determinant, then \tilde{f} is the determinant of $\xi_{r_1}, \dots, \xi_{r_n}$.

Suppose that $f(v_1, \dots, v_m) = \bar{v}_{ri}$. Then

$$\begin{aligned} (1) \quad f(A \cdot (v_1, \dots, v_m)) &= \text{the conjugate of the } i^{\text{th}} \text{ component of } v_r \cdot A^t \\ &= \text{the conjugate of } \sum_j a_{ij} v_{rj} \\ &= \sum_j \bar{a}_{ij} \bar{v}_{rj}. \end{aligned}$$

On the other hand, if $A \in U(n)$, so that $A^{-1} = \bar{A}^t$, then

$$\begin{aligned} (2) \quad \tilde{f}(A \cdot (v_1, \dots, v_m, \xi_1, \dots, \xi_m)) \\ &= \tilde{f}(v_1 \cdot A^t, \dots, v_m \cdot A^t, (A^{-1})^t \cdot \xi_1, \dots, (A^{-1})^t \cdot \xi_m) \\ &= i^{\text{th}} \text{ component of } (A^{-1})^t \cdot \xi_r \\ &= i^{\text{th}} \text{ component of } \bar{A} \cdot \xi_r \\ &= \sum_j \bar{a}_{ij} \xi_{rj}. \end{aligned}$$

Comparing (1) and (2), we see that

$$(3) \quad \tilde{f} \circ (A \cdot) = \widetilde{f \circ (A \cdot)},$$

where $(A \cdot)$ on the left is the action of $A \in U(n)$ on $\mathbb{C}^n \times \dots \times (\mathbb{C}^n)^*$, while $(A \cdot)$ on the right is the action of A on $\mathbb{C}^n \times \dots \times \mathbb{C}^n$. From the way that $f \mapsto \tilde{f}$ is defined, it is clear that (3) holds for all f . Consequently,

f is invariant under $U(n)$ if and only if \tilde{f} is invariant under $U(n)$.

From this we immediately conclude

64. THEOREM. Let $f: \mathbb{C}^n \times \dots \times \mathbb{C}^n \rightarrow \mathbb{C}$ be a polynomial function in the components of the vectors of \mathbb{C}^n and the conjugates of the components which is invariant under $SU(n)$. Then f is a polynomial in the Hermitian inner products and the determinants \det_{r_1, \dots, r_n} and their conjugates $\overline{\det_{r_1, \dots, r_n}}$.

PROOF. By Corollary 63, the function \tilde{f} is a polynomial in the evaluations ε_{rs} and the determinants \det_{r_1, \dots, r_n} and \det_{r_1, \dots, r_n}^* . Since

$$\varepsilon_{rs} = \widetilde{t_{rs}}, \quad \det_{r_1, \dots, r_n} = \overline{\det_{r_1, \dots, r_n}}, \quad \det_{r_1, \dots, r_n}^* = \overline{\det_{r_1, \dots, r_n}},$$

the result follows. ♦

In order to prove Theorem 49, which gives the corresponding result for $U(n)$, we need just one more observation. Let $v_1, \dots, v_n, w_1, \dots, w_n \in \mathbb{C}^n$, and let $A = (v_{ij}), B = (w_{ij})$. Then we have

$$(A \cdot \bar{B}^t)_{ij} = \sum_k v_{ik} \overline{w_{jk}} = \langle v_i, w_j \rangle,$$

where $\langle \cdot, \cdot \rangle$ is the Hermitian inner product. Hence

$$(*) \quad \det A \overline{\det B} = \det(\langle v_i, w_j \rangle).$$

PROOF OF THEOREM 49. Since f is invariant under $SU(n)$, by Theorem 64 it can be written as a polynomial in the Hermitian inner products and

$$\det_{r_1, \dots, r_n} \quad \text{and} \quad \overline{\det_{s_1, \dots, s_n}}.$$

The action of an element $A \in U(n)$ multiplies the latter two by

$$\det A \quad \text{and} \quad \overline{(\det A)} = \det \bar{A} = \det(A^{-1})^t = (\det A)^{-1}.$$

Hence every factor \det_{r_1, \dots, r_n} must come paired with a factor $\overline{\det_{s_1, \dots, s_n}}$. But (*) says that the product of these two functions can be expressed in terms of the Hermitian inner product functions. ♦

ADDENDUM 2

RECOVERING THE DIFFERENTIAL FORMS;
THE GAUSS-BONNET-CHERN THEOREM
FOR MANIFOLDS-WITH-BOUNDARY

The crucial step in our proof of the generalized Gauss-Bonnet theorem was Theorem 22, for it immediately allowed us to conclude that if $\xi = \pi: E \rightarrow M$ is an oriented n -dimensional vector bundle, with sphere bundle $\pi_0: S \rightarrow M$, then $\pi_0^*C(\xi) = 0$. This means that if Λ is the n -form on M representing $C(\xi)$, then the n -form $\pi_0^*\Lambda$ on S is exact,

$$\pi_0^*\Lambda = d\Phi \quad \text{for some } (n-1)\text{-form } \Phi \text{ on } S.$$

In particular, suppose that $\xi = TM^n$, and let X be a unit vector field on M with a single isolated singularity, at $p \in M$ (Problem I.11-13). Let $B(\varepsilon)$ be a closed ball of radius ε around p , and set

$$M_\varepsilon = M - \text{interior } B(\varepsilon).$$

Then $X(M_\varepsilon) \subset S$ is a manifold-with-boundary, the image of M_ε under the section $X: M - \{p\} \rightarrow S$. Now

$$\begin{aligned} \int_M \Lambda &= \int_{M-\{p\}} \Lambda = \lim_{\varepsilon \rightarrow 0} \int_{M_\varepsilon} \Lambda = \lim_{\varepsilon \rightarrow 0} \int_{M_\varepsilon} X^*(\pi_0^*\Lambda) \\ &= \lim_{\varepsilon \rightarrow 0} \int_{X(M_\varepsilon)} \pi_0^*\Lambda = \lim_{\varepsilon \rightarrow 0} \int_{X(M_\varepsilon)} d\Phi \\ &= \lim_{\varepsilon \rightarrow 0} \int_{\partial X(M_\varepsilon)} \Phi. \end{aligned}$$

Recalling the definition of the index of X at p , we easily see that

$$\begin{aligned} (1) \quad \int_M \Lambda &= (\text{index of } X \text{ at } p) \cdot \int_{\pi_0^{-1}(p)} \Phi \\ &= \chi(M) \cdot \int_{\pi_0^{-1}(p)} \Phi \quad \text{by Theorem I.11-30.} \end{aligned}$$

Since for $n = 2m$ we also have

$$(2) \quad \int_M \Lambda = \int_M n! K_n dV = \pi^m m! 2^n \chi(M) \quad \text{by Theorem 26,}$$

we obtain, finally,

$$(3) \quad \int_{\pi_0^{-1}(p)} \Phi = \pi^m m! 2^n.$$

In the original intrinsic proof of the generalized Gauss-Bonnet theorem, Chern [2] did not use Theorem 22 or Corollaries 23 and 24. Instead, by clever guess-work he explicitly constructed a form Φ with $\pi_0^* \Lambda = d\Phi$, and noted that it satisfied equation (3). By applying equation (1), he thus deduced equation (2), which is precisely the generalized Gauss-Bonnet theorem. As we will soon see, it is very useful to have an explicit formula for Φ when we seek a generalized Gauss-Bonnet theorem for manifolds-with-boundary.

Let $(M, \partial M)$ be a compact orientable manifold-with-boundary. The Euler characteristic $\chi(M)$ is defined, as before, by

$$\chi(M) = \dim H^0(M) - \dim H^1(M) + \dots.$$

With some work, we could generalize Theorem I.11-5, and show that $\chi(M) = \alpha_0 - \alpha_1 + \dots$, where α_k is the number of k -simplexes in a triangulation. But we won't pause to prove this, because other facts about $\chi(M)$ are more important for us. First note that we can construct a compact oriented manifold DM , the **double** of M , by taking two disjoint copies of M , and identifying the corresponding points of ∂M . The following result is obvious in terms of

triangulations, but we will give an independent proof.

65. PROPOSITION. The Euler characteristic of DM is given by

$$\chi(DM) = 2\chi(M) - \chi(\partial M).$$

PROOF. Let U and V be open neighborhoods of the two copies of M in DM such that $H^k(U) \approx H^k(V) \approx H^k(M)$ for all k , and $H^k(U \cap V) \approx H^k(\partial M)$ for all k . Then we have the Mayer-Vietoris sequence (Theorem I.11-3)

$$\begin{aligned} 0 \rightarrow H^0(DM) \rightarrow \dots \rightarrow H^k(DM) \rightarrow H^k(U) \oplus H^k(V) \rightarrow \\ \rightarrow H^k(U \cap V) \xrightarrow{\delta} H^{k+1}(DM) \rightarrow \dots \end{aligned}$$

When we apply Proposition I.11-4, we obtain precisely the desired result. ♦

This result says quite different things when the dimension n of M is odd or even. For odd n we have $\chi(DM) = 0$ (Corollary I.11-25), so we obtain

$$\chi(M) = \frac{1}{2}\chi(\partial M);$$

in particular $\chi(\partial M)$ must be even. For even n , we have $\chi(\partial M) = 0$, so we have

$$(*) \quad 2\chi(M) = \chi(DM).$$

66. COROLLARY. Let M be a compact orientable manifold-with-boundary, of even dimension n . Let X be a vector field on M with only finitely many zeros, all in $M - \partial M$, such that X is outward pointing on ∂M . Then the sum of the indices of X is $\chi(M)$.

PROOF. We can modify X near ∂M so that X is the outward pointing unit normal ν on ∂M (and so that there are no new zeros). Then there is a vector field on DM which looks like X on one copy of M and like $-X$ on the other copy. Since n is even, the index of $-X$ at an isolated zero is the same as the index of X at that zero (Problem I.11-12). Thus Theorem I.11-30 gives

$$2(\text{sum of the indices of } X) = \chi(DM) = 2\chi(M), \quad \text{by } (*). \quad \spadesuit$$

67. COROLLARY. Let M be a compact oriented Riemannian manifold-with-boundary, of even dimension $n = 2m$, with tangent bundle $\pi: TM \rightarrow M$, and associated sphere bundle $\pi_0 = \pi|_S: S \rightarrow M$. Let ω be a connection on the principal bundle $\varpi: \text{SO}(TM) \rightarrow M$, with curvature form Ω , let Λ be the unique n -form on M with

$$\varpi^* \Lambda = \sum \varepsilon^{i_1 \dots i_n} \Omega_{i_2}^{i_1} \wedge \dots \wedge \Omega_{i_n}^{i_{n-1}} = 2^m m! \text{Pf}(\Omega),$$

and let Φ be an $(n-1)$ -form on S with

$$\pi_0^* \Lambda = d\Phi.$$

Finally, let $\nu: \partial M \rightarrow S$ be the outward pointing unit normal on ∂M . Then

$$\int_M K_n dV = \frac{1}{n!} \int_M \Lambda = \frac{\pi^m m! 2^n}{n!} \chi(M) + \frac{1}{n!} \int_{\partial M} \nu^* \Phi.$$

PROOF. Extend ν to a vector field X on M with only finitely many zeros $p_1, \dots, p_k \in M - \partial M$. Let $B_i(\varepsilon)$ be closed balls of radius ε around p_i which are disjoint from each other and from ∂M , and set

$$M_\varepsilon = M - \bigcup_{i=1}^k \text{interior } B_i(\varepsilon).$$

Then, as on page 380, we have

$$\begin{aligned} \int_M \Lambda &= \lim_{\varepsilon \rightarrow 0} \int_{\partial X(M_\varepsilon)} \Phi \\ &= \int_{\nu(\partial M)} \Phi + \sum_{i=1}^k \lim_{\varepsilon \rightarrow 0} \int_{\partial B_i(\varepsilon)} \Phi \\ &= \int_{\partial M} \nu^* \Phi + \sum_{i=1}^k \pi^m m! 2^n \cdot (\text{index of } X \text{ at } p_i) \quad \text{by (3), on page 381} \\ &= \int_{\partial M} \nu^* \Phi + \pi^m m! 2^n \cdot \chi(M) \quad \text{by Corollary 66. } \spadesuit \end{aligned}$$

The only trouble with this result is that we can't interpret $\int_{\partial M} \nu^* \Phi$ until we have an explicit Φ with $\pi_0^* \Lambda = d\Phi$. Fortunately, we can pull a Φ out of the air by looking more carefully at the proofs in section 4.

First consider two connections on the principal bundle $\text{SO}(E)$, as in Proposition 20. Changing notation slightly, we denote these connections by ω and $\tilde{\omega}$, with curvature forms Ω and $\tilde{\Omega}$. Let Λ and $\tilde{\Lambda}$ be the forms with

$$\varpi^*(\Lambda) = 2^m m! \text{Pf}(\Omega) \quad \text{and} \quad \varpi^*(\tilde{\Lambda}) = 2^m m! \text{Pf}(\tilde{\Omega}).$$

All quantities associated with $M \times [0, 1]$ will be written boldface, so the induced connections $q^* \omega$ and $q^* \tilde{\omega}$ in the proof of Proposition 20 will be denoted by

$$\omega = q^* \omega \quad \text{and} \quad \tilde{\omega} = q^* \tilde{\omega},$$

and we will set

$$\Psi = (1 - \tau)\omega + \tau\tilde{\omega}.$$

Note that $\partial/\partial\tau$ is horizontal for these connections.

The proof of Proposition 20 tells us how to find a form Φ with $d\Phi = \tilde{\Lambda} - \Lambda$. To obtain Φ explicitly, we first want to describe the curvature form Ψ of ψ more explicitly. Note that tangent vectors on $M \times [0, 1]$ can be considered as sums

$$X + \mu \frac{\partial}{\partial \tau} \quad \mu \in \mathbb{R}$$

where X is a tangent vector of M , and tangent vectors on the total space of $q^* \text{SO}(\xi)$ can be considered as sums

$$Y + \mu \frac{\partial}{\partial \tau}$$

where Y is a tangent vector on $\text{SO}(E)$. We have

$$d\psi = (1 - \tau)d\omega + \tau d\tilde{\omega} + d\tau \wedge (\tilde{\omega} - \omega),$$

so for two tangent vectors $Y_1 + \mu_1 \partial/\partial \tau$ and $Y_2 + \mu_2 \partial/\partial \tau$ on the total space of $q^* \text{SO}(\xi)$ we have

$$\begin{aligned} \Psi(Y_1 + \mu_1 \partial/\partial \tau, Y_2 + \mu_2 \partial/\partial \tau) &= d\psi(h(Y_1 + \mu_1 \partial/\partial \tau), h(Y_2 + \mu_2 \partial/\partial \tau)) \\ &= [(1 - \tau)d\omega + \tau d\tilde{\omega}](h(Y_1) + \mu_1 \partial/\partial \tau, h(Y_2) + \mu_2 \partial/\partial \tau) \\ &\quad + [d\tau \wedge (\tilde{\omega} - \omega)](Y_1 + \mu_1 \partial/\partial \tau, Y_2 + \mu_2 \partial/\partial \tau), \\ &\text{since } \tilde{\omega} - \omega = 0 \text{ on vertical vectors.} \end{aligned}$$

Extending Y_2 to a vector field, we have

$$d\omega(\partial/\partial \tau, h(Y_2)) = \frac{\partial}{\partial \tau}(\omega(h(Y_2)) - h(Y_2)(\omega(\partial/\partial \tau)) - \omega([\partial/\partial \tau, h(Y_2)]).$$

The first term on the right must vanish, since we can choose the vector field Y_2 to be independent of τ ; the second vanishes, since $\partial/\partial \tau$ is horizontal for ω ; and it is easily seen that the third term also vanishes (compare pg. IV.370). So if Ω and $\tilde{\Omega}$ are the curvature forms for ω and $\tilde{\omega}$, then we have, finally,

$$\begin{aligned} \Psi &= (1 - \tau)\Omega + \tau\tilde{\Omega} + d\tau \wedge (\tilde{\omega} - \omega) \\ &= \Omega + \tau(\tilde{\Omega} - \Omega) + d\tau \wedge (\tilde{\omega} - \omega). \end{aligned}$$

From this expression we see that

$$\begin{aligned} 2^m m! \text{Pf}(\Psi) &= \sum_{i_1, \dots, i_n} \varepsilon^{i_1 \dots i_n} \Psi_{i_2}^{i_1} \wedge \dots \wedge \Psi_{i_n}^{i_{n-1}} \\ &= \sum_{i_1, \dots, i_n} \varepsilon^{i_1 \dots i_n} \Omega_{i_2}^{i_1} \wedge \dots \wedge \Omega_{i_n}^{i_{n-1}} \\ &\quad + d\tau \wedge \mathbf{H}, \end{aligned}$$

where \mathbf{H} is a linear combination of terms of the form

$$(*) \quad \tau^{m-k-1} \sum_{i_1, \dots, i_n} \varepsilon^{i_1 \dots i_n} \Omega_{i_2}^{i_1} \wedge \dots \wedge \Omega_{i_{2k}}^{i_{2k-1}} \wedge (\tilde{\Omega} - \Omega)_{i_{2k+2}}^{i_{2k+1}} \wedge \dots \wedge \\ \wedge (\tilde{\Omega} - \Omega)_{i_{n-2}}^{i_{n-3}} \wedge (\tilde{\omega} - \omega)_{i_n}^{i_{n-1}}.$$

We won't bother keeping track of the exact coefficients involved in our calculations, since there will be a cheap way of getting them out at the end. Our expression for $2^m m! \text{Pf}(\Psi)$ shows that the closed n -form Λ on $M \times [0, 1]$ which pulls back to $2^m m! \text{Pf}(\Psi)$ can be written

$$\Lambda = \dots + d\tau \wedge \eta,$$

where η is a linear combination of forms which pull back* to the forms $(*)$. Now Theorem I.7-17 says that

$$\tilde{\Lambda} - \Lambda = i_1^* \Lambda - i_0^* \Lambda = d(I\Lambda),$$

where

$$I\Lambda(p)(X_1, \dots, X_{n-1}) = \int_0^1 \eta(p, t)(i_{t*} X_1, \dots, i_{t*} X_{n-1}) dt.$$

In this integral, t will enter only in the factors t^{m-k-1} . All other terms are independent of t , since the connections ω and $\tilde{\omega}$ are independent of t —for a tangent vector Y on $\text{SO}(E)$ we have $\omega(i_{t*} Y) = \omega(Y)$, and similarly for $\tilde{\omega}$, Ω , and $\tilde{\Omega}$. So we see, finally, that

(A) $\tilde{\Lambda} - \Lambda = d\Phi$, where the $(n-1)$ -form Φ on M is a linear combination of $(n-1)$ -forms which pull back to the forms

$$(**) \quad \sum_{i_1, \dots, i_n} \varepsilon^{i_1 \dots i_n} \Omega_{i_2}^{i_1} \wedge \dots \wedge \Omega_{i_{2k}}^{i_{2k-1}} \wedge (\tilde{\Omega} - \Omega)_{i_{2k+2}}^{i_{2k+1}} \wedge \dots \wedge \\ \wedge (\tilde{\Omega} - \Omega)_{i_{n-2}}^{i_{n-3}} \wedge (\tilde{\omega} - \omega)_{i_n}^{i_{n-1}}$$

on $\text{SO}(E)$.

It is easy to see that there are forms with this property, since Ω , $\tilde{\Omega}$, and $\tilde{\omega} - \omega$ vanish on vertical vectors. The proof is similar to that of Proposition 18, except that in the second part we explicitly write out the value of the form $()$ on $R_A^* Y_1, \dots, R_A^* Y_{n-1}$, noting that $R_A^* \omega = A^{-1} \omega A$ and $R_A^* \tilde{\omega} = A^{-1} \tilde{\omega} A$, by the definition of a connection. Then we check that this is $\det A = 1$ times the value of the form on Y_1, \dots, Y_{n-1} , the computation being similar to that in the proof of Proposition 9.

Now we will apply this to a special, complicated, case. Let $\xi = \pi: E \rightarrow M$ be an n -dimensional vector bundle with a Riemannian metric $\langle \cdot, \cdot \rangle$, let $\text{SO}(\xi) = \varpi: \text{SO}(E) \rightarrow M$ be the corresponding principal bundle, and let $\pi_0: S \rightarrow M$ be the corresponding sphere bundle. Set

$$\zeta = \pi_0^* \xi = p: \mathbf{E} \rightarrow M;$$

the total space \mathbf{E} consists of all pairs (e, v) where $e \in S$ and $v \in \pi(e)$. For the corresponding principal bundle

$$\text{SO}(\zeta) = \rho: \text{SO}(\mathbf{E}) \rightarrow S,$$

the fibre over e is the set of all (e, u) where $u \in \varpi^{-1}(\pi(e))$ is an orthonormal frame at $\pi(e)$. The principal bundle map

$$\begin{array}{ccc} \text{SO}(\mathbf{E}) & \xrightarrow{\tilde{\pi}_0} & \text{SO}(E) \\ \downarrow \rho & & \downarrow \varpi \\ S & \xrightarrow{\pi_0} & M \end{array}$$

$\tilde{\pi}_0: \text{SO}(\mathbf{E}) \rightarrow \text{SO}(E)$

which covers π_0 takes (e, u) to u .

Recall that we can write

$$\zeta = \zeta_1 \oplus \zeta_2,$$

where

$\zeta_1 = p_1: \mathbf{E}_1 \rightarrow M$ is an $(n-1)$ -dimensional bundle,

$\zeta_2 = p_2: \mathbf{E}_2 \rightarrow M$ is a trivial 1-dimensional bundle;

the total space $\mathbf{E}_2 \subset \mathbf{E}$ consists of all pairs $(e, \mu e)$ for $e \in S$ and $\mu \in \mathbb{R}$, while $\mathbf{E}_1 \subset \mathbf{E}$ consists of all pairs (e, v) where $v \in \pi(e)$ is orthogonal to e . For the corresponding principal bundles

$$\text{SO}(\zeta_i) = \rho_i: \text{SO}(\mathbf{E}_i) \rightarrow S,$$

the fibre $\rho_2^{-1}(e)$ contains just the two pairs (e, e) and $(e, -e)$, while the fibre $\rho_1^{-1}(e)$ consists of all pairs (e, v) where v is an ordered $(n-1)$ -tuple of orthonormal vectors at $\pi(e)$ all of which are perpendicular to e . We have a natural inclusion

$$\iota: \text{SO}(\mathbf{E}_1) \rightarrow \text{SO}(\mathbf{E}),$$

which takes (e, v) to (e, u) where u is the frame whose first $n-1$ members come from v , while $u_n = e$. Clearly,

$$\begin{array}{ccc} \text{SO}(\mathbf{E}_1) & \xrightarrow{\iota} & \text{SO}(\mathbf{E}) \\ & \searrow p_1 & \downarrow p \\ & & S \end{array}$$

$p \circ \iota = p_1.$

Now let ω be a connection on $\text{SO}(E)$, with curvature form Ω . Then

$$\gamma = \tilde{\pi}_0^* \omega$$

is a connection on $\text{SO}(\mathbf{E})$, whose curvature form Γ is $\tilde{\pi}_0^* \Omega$. Hence if Λ is the unique form on M with

$$\varpi^* \Lambda = 2^m m! \text{Pf}(\Omega),$$

then

$$(1) \quad p^* \pi_0^* \Lambda = \tilde{\pi}_0^* \varpi^* \Lambda = 2^m m! \text{Pf}(\tilde{\pi}_0^* \Omega) = 2^m m! \text{Pf}(\Gamma).$$

We can also use γ to determine a connection γ_1 on $\text{SO}(\mathbf{E}_1)$ by

$$(\gamma_1)_j^i = \iota^* \gamma_j^i \quad i, j = 1, \dots, n-1.$$

The two conditions

$$\begin{aligned} \gamma_1(\sigma(M)) &= M & \text{for } M \in \mathfrak{o}(n-1) \\ R_A^* \gamma_1 &= \text{Ad}(A^{-1}) \gamma_1 & \text{for } A \in \text{SO}(n-1) \end{aligned}$$

follow from the corresponding conditions for γ —if we regard $\text{SO}(\mathbf{E}_1) \subset \text{SO}(\mathbf{E})$ via the map ι , then $\sigma(M)$ in $\text{SO}(\mathbf{E}_1)$ is the restriction of $\sigma(M)$ in $\text{SO}(\mathbf{E})$ for $M \in \mathfrak{o}(n-1)$, and R_A in $\text{SO}(\mathbf{E}_1)$ is the restriction of $R_{\tilde{A}}$ in $\text{SO}(\mathbf{E})$, where $\tilde{A} = \begin{pmatrix} A & 0 \\ 0 & 1 \end{pmatrix}$.

Although $(\gamma_1)_j^i = \iota^* \gamma_j^i$ for $i, j = 1, \dots, n-1$, it does not follow for these same values of i and j that the curvature forms Γ_1 and Γ satisfy $(\Gamma_1)_j^i = \iota^* \Gamma_j^i$; for the horizontal component in $\text{SO}(\mathbf{E}_1)$ is different from the horizontal component in $\text{SO}(\mathbf{E})$. To find the correct relationship, we use the second structural equation (Theorem II.8-16),

$$d\gamma(Y_1, Y_2) = -[\gamma(Y_1), \gamma(Y_2)] + \Gamma(Y_1, Y_2)$$

for tangent vectors Y_1, Y_2 on $\text{SO}(\mathbf{E})$, which means that

$$(2) \quad d\gamma_j^i(Y_1, Y_2) = - \sum_{k=1}^n \gamma_k^i(Y_1) \gamma_j^k(Y_2) - \gamma_k^i(Y_2) \gamma_j^k(Y_1) + \Gamma_j^i(Y_1, Y_2).$$

Similarly, for tangent vectors Z_1, Z_2 on $\text{SO}(\mathbf{E}_1)$, we have

$$d(\gamma_1)_j^i(Z_1, Z_2) = - \sum_{k=1}^{n-1} (\gamma_1)_k^i(Z_1) (\gamma_1)_j^k(Z_2) - (\gamma_1)_k^i(Z_2) (\gamma_1)_j^k(Z_1) + (\Gamma_1)_j^i(Z_1, Z_2)$$

which implies

$$(3) \quad d\gamma_j^i(\iota_* Z_1, \iota_* Z_2) = - \sum_{k=1}^{n-1} \gamma_k^i(\iota_* Z_1) \gamma_j^k(\iota_* Z_2) - \gamma_k^i(\iota_* Z_2) \gamma_j^k(\iota_* Z_1) + (\Gamma_1)_j^i(Z_1, Z_2).$$

Comparing (2) and (3), we see that

$$(4) \quad (\Gamma_1)_j^i = \iota^* \Gamma_j^i + \iota^*(\gamma_n^i \wedge \gamma_n^j) \quad i, j = 1, \dots, n-1.$$

Now we are going to apply the construction in the proof of Theorem 22. The principal bundle $\text{SO}(\mathbf{E}_2)$ for the 1-dimensional bundle ζ_2 is just 2 copies of M ; the only connection on $\text{SO}(\mathbf{E}_2)$ is $\gamma_2 = 0$. The bundle $\text{SO}(\mathbf{E}_1) * \text{SO}(\mathbf{E}_2) \subset \text{SO}(\mathbf{E})$ in the proof of Theorem 22 is just 2 copies of $\text{SO}(\mathbf{E}_1)$; the first copy may be identified with $\iota(\text{SO}(\mathbf{E}_1))$. The connection

$$\bar{\gamma} = \rho_1^* \gamma_1 \oplus \rho_2^* \gamma_2$$

on $\text{SO}(\mathbf{E}_1) * \text{SO}(\mathbf{E}_2)$ which is constructed in the proof of Theorem 22 is just $\iota^* \gamma_1$ on the first copy, and similarly the curvature form $\bar{\Gamma}$ is just $\iota^* \Gamma_1$ on the first copy. As before, we extend the connection $\bar{\gamma}$ to a connection $\tilde{\gamma}$ on $\text{SO}(\mathbf{E})$, with curvature form $\tilde{\Gamma}$. We have unique forms $\Upsilon, \tilde{\Upsilon}$ on S with

$$\begin{aligned} p^* \Upsilon &= 2^m m! \text{Pf}(\Gamma) \\ p^* \tilde{\Upsilon} &= 2^m m! \text{Pf}(\tilde{\Gamma}). \end{aligned}$$

But equation (1) says that $\Upsilon = \pi_0^* \Lambda$, while, as in the proof of Theorem 22, we have $\text{Pf}(\tilde{\Gamma}) = 0$ at points of $\text{SO}(\mathbf{E}_1) * \text{SO}(\mathbf{E}_2)$, which implies that $\tilde{\Upsilon} = 0$. Assertion (A) on page 385 thus shows that

$\pi_0^* \Lambda = d\Phi$, where the $(n-1)$ -form Φ on S is a linear combination of $(n-1)$ -forms which pull back, via p^* , to the forms

$$\sum_{i_1, \dots, i_n} \varepsilon^{i_1 \dots i_n} \Gamma_{i_2}^{i_1} \wedge \dots \wedge \Gamma_{i_{2k}}^{i_{2k-1}} \wedge (\tilde{\Gamma} - \Gamma)_{i_{2k}}^{i_{2k+1}} \wedge \dots \wedge (\tilde{\Gamma} - \Gamma)_{i_{n-2}}^{i_{n-3}} \wedge (\tilde{\gamma} - \gamma)_{i_n}^{i_{n-1}}.$$

But on tangent vectors to $\text{SO}(\mathbf{E}_1) * \text{SO}(\mathbf{E}_2) = 2$ copies of $\text{SO}(\mathbf{E}_1)$, we clearly have

$$(\tilde{\gamma} - \gamma)_j^i = \begin{cases} 0 & i, j \neq n \\ \iota^* \gamma_j^i & i \text{ or } j = n \end{cases} \quad \text{on the first copy,}$$

while equation (4) shows that we also have

$$(\tilde{\Gamma} - \Gamma)_j^i = \begin{cases} \iota^*(\gamma_n^i \wedge \gamma_n^j) & i, j \neq n \\ -\iota^* \Gamma_j^i & i \text{ or } j = n \end{cases} \quad \text{on the first copy.}$$

Hence, remembering that $\gamma = \tilde{\pi}_0^* \omega$ and $\Gamma = \tilde{\pi}_0^* \Omega$, we can conclude that

$\pi_0^* \Lambda = d\Phi$, where the $(n-1)$ -form Φ on S is a linear combination of $(n-1)$ -forms Φ_k , $0 \leq k \leq m-1$, such that

$$\begin{aligned} p_1^* \Phi_k &= \iota^* p^* \Phi_k \\ &= \iota^* \tilde{\pi}_0^* \left(\sum_{i_1, \dots, i_{n-1}} \varepsilon^{i_1 \dots i_{n-1}} \Omega_{i_2}^{i_1} \wedge \dots \wedge \Omega_{i_{2k}}^{i_{2k-1}} \right. \\ &\quad \left. \wedge \omega_n^{i_{2k+1}} \wedge \dots \wedge \omega_n^{i_{n-1}} \right); \end{aligned}$$

in this sum, the indices i_α run from 1 to $n-1$.

This can be put in a more useful form by introducing the “last vector” map $\ell: \text{SO}(E) \rightarrow S$ defined by

$$\ell(u) = u_n.$$

We clearly have

$$\ell \circ \tilde{\pi}_0 \circ \iota = p_1: \text{SO}(E_1) \rightarrow S.$$

It is easy to check that there are unique forms Θ_k on S such that

$$\ell^* \Theta_k = \sum_{i_1, \dots, i_{n-1}} \varepsilon^{i_1 \dots i_{n-1}} \Omega_{i_2}^{i_1} \wedge \dots \wedge \Omega_{i_{2k}}^{i_{2k-1}} \wedge \omega_n^{i_{2k+1}} \wedge \dots \wedge \omega_n^{i_{n-1}};$$

we use the procedure given in the footnote on page 385, noting that in the

second part we only want to consider $A \in \text{SO}(n)$ with $\ell(u \cdot A) = \ell(u)$, so that $A = \begin{pmatrix} B & 0 \\ 0 & 1 \end{pmatrix}$ for $B \in \text{SO}(n-1)$. But now we have

$$\begin{aligned} p_1^* \Phi_k &= \iota^* \tilde{\pi}_0^* \ell^* \Theta_k = p_1^* \Theta_k \\ \implies \Phi_k &= \Theta_k. \end{aligned}$$

So we can state, finally,

(B) There are constants a_0, \dots, a_{m-1} such that

$$\pi_0^* \Lambda = \sum_{k=0}^{m-1} a_k \Phi_k,$$

where the Φ_k are the unique forms on S such that

$$\ell^* \Phi_k = \sum_{i_1, \dots, i_{n-1}} \varepsilon^{i_1 \dots i_{n-1}} \Omega_{i_2}^{i_1} \wedge \dots \wedge \Omega_{i_{2k}}^{i_{2k-1}} \wedge \omega_n^{i_{2k+1}} \wedge \dots \wedge \omega_n^{i_{n-1}}.$$

Note that the constants a_0, \dots, a_{m-1} do not depend on the bundle, or anything else; they are certain combinatorial terms in a formal calculation which is exactly the same for all bundles. If we apply Corollary 67, we obtain

$$(*) \quad \int_M K_n dV = \frac{\pi^m m! 2^n}{n!} \chi(M) + \frac{1}{n!} \sum_{k=0}^{m-1} a_k \int_{\partial M} \nu^* \Phi_k.$$

If we choose a positively oriented orthonormal moving frame $\mathbf{X} = (X_1, \dots, X_n)$ on ∂M with $X_n = \nu$, then

$$\nu = \ell \circ \mathbf{X}, \quad \mathbf{X}: \partial M \rightarrow \text{SO}(E),$$

so

$$\begin{aligned} \nu^* \Phi_k &= \mathbf{X}^* \ell^* \Phi_k \\ &= \sum_{i_1, \dots, i_{n-1}} \varepsilon^{i_1 \dots i_{n-1}} (\mathbf{X}^* \Omega_{i_2}^{i_1}) \wedge \dots \wedge (\mathbf{X}^* \Omega_{i_{2k}}^{i_{2k-1}}) \\ &\quad \wedge (\mathbf{X}^* \omega_n^{i_{2k+1}}) \wedge \dots \wedge (\mathbf{X}^* \omega_n^{i_{n-1}}). \end{aligned}$$

Recall that ω and Ω are forms on $\text{SO}(E)$; the terms $\mathbf{X}^* \omega_n^{i_{2k+1}}$ and $\mathbf{X}^* \Omega_{i_2}^{i_1}$ are just the corresponding connection and curvature forms for the moving frame \mathbf{X} .

This allows us to give an invariant definition of $\nu^*\Phi_k$ similar to the invariant definition of $\Lambda/n! = K_n dV$: if dV_{n-1} denotes the volume element on ∂M , then

$$\nu^*\Phi_k = K_k dV_{n-1},$$

where K_k can be written as a contraction of tensor products of the tensor \mathfrak{e} on ∂M (contravariant of order $n-1$), the curvature tensor \mathcal{R} for ∂M , and the tensor

$$(X, Y) \mapsto \langle \nabla_X \nu, Y \rangle,$$

which is just the second fundamental form of ∂M in M .

To calculate the constants a_0, \dots, a_{m-1} , we just have to apply equation (*) to products $M = D^{k+1} \times S^{n-k-1}$, with $\partial M = S^k \times S^{n-k-1}$; then the only non-zero boundary integral is the one involving $\nu^*\Phi_k$. The explicit calculations are left to the reader—after doing them, it should be fun to compare with Chern's paper [2].

BIBLIOGRAPHY

Part A of the bibliography describes the main topics of differential geometry not included in these volumes, as well as many subsidiary topics. Part B lists books, monographs, etc., referred to by curly brackets { }, while Part C lists individual journal articles, referred to by square brackets [].

The list of journal articles is rudimentary, containing only a few articles not specifically referred to in the text; no serious attempt has been made to provide historical background or to attribute theorems justly. A more than adequate supply of references can be obtained from the extensive bibliographies in some of the books listed in Part B, and of course there's always *Mathematical Reviews*.

A. OTHER TOPICS IN DIFFERENTIAL GEOMETRY

I. Major topics everyone should know something about.*

(a) *Complex manifolds*. This is the main topic which was hardly touched upon in these notes. Some people heartily dislike the subject, with its penetrating algebraic odor, but for others it has a seductive appeal. A differential geometer whose work often uses the simplifications obtained by considering the complex domain explained to me that the additional structure of complex manifolds makes them more interesting, just as two sexes are more interesting than one, but various aspects of this argument are open to debate. A basic treatment of complex manifolds is given in Kobayashi and Nomizu {1; v.2, ch.9}. See also Chern {1}, Weil {1}, Wu {1}, and Yano {2}. For more emphasis on the analysis aspects, see Griffiths {1}, Morrow and Kodaira {1}, and Wells {1}.

(b) *Homogeneous spaces*. In Chapter 13 we defined a “homogeneous space” to be a quotient space G/H . The terminology comes from the fact that these are precisely the manifolds M on which G acts transitively (see Warner {1; 120ff.} or Wolf {1; 11–13}); one should also be aware of the usage in the case of Riemannian manifolds (cf. Kobayashi and Nomizu {1; v.1, 176}). Once the identification with G/H is made, further study of these spaces becomes rather algebraic. See Kobayashi and Nomizu {1; v.2, ch.10}. It should also be mentioned that homogeneous spaces provide the natural setting for geometry according to the famous definition proposed by Felix Klein [1], of geometry as the theory of geometric invariants of a transitive transformation group. Even such subjects as Riemannian geometry have been brought within the compass of this definition, essentially by means of connections on certain principal bundles. There are some older references at the end of Chapter 2 of Veblen and Whitehead {1}, but the most extensive treatment is given by Sharpe {1}.

(c) *Symmetric spaces*. A very nice brief introduction to (Riemannian) symmetric spaces can be found in Milnor {2; §§20, 21}. Increasing detail, and algebra, can be found in Wolf {1}, Kobayashi and Nomizu {1; v.2, ch.11}, Boothby and Weiss {1}, Loos {1}, and the standard treatise Helgason {1}, with specialized material in Eberlein {1}.

(d) *Mappings*. Numerous types of maps between Riemannian manifolds are of importance—*isometries*, *similarities* (which multiply the metrics by a constant), *conformal maps* (which multiply the metrics by a function), *affine maps* (which take geodesics into geodesics), and *projective maps* (which take geodesics into

* As evidenced by the fact that they get a chapter apiece in Kobayashi and Nomizu {1}.

reparameterized geodesics); the latter two can be defined for arbitrary connections. We might also mention [essential] volume preserving maps, which preserve volumes of open subsets [up to a constant factor]. Certain classical relations between such maps, not mentioned here, may be found, for example, in Laugwitz {1; 147–161}. In preference to Theorem 13.4.6, one may consult Lemma 1 on pg. 242 of Kobayashi and Nomizu {1; v.1} (Laugwitz defines “irreducible” incorrectly); their proof of Lemma 2 on the same page is perhaps also somewhat preferable to Laugwitz’s proof of the corresponding Theorem 13.6.2. One other classical result may be found in Haack {1; 130–133} or Kreyszig {1; 267–269}. Naturally, the study of maps from S^2 to \mathbb{R}^2 has received special attention. Although cartography is an independent subject, the reader will probably find more than enough information about it in classical differential geometry books, for example Kreyszig {1} and Laugwitz {1}, or Scheffers {1; v.2, 36–53} and Strubecker {1; v.2, 170–201} for more examples. In addition to the maps themselves, one can study vector fields which represent “infinitesimal” versions of them. In particular, the infinitesimal versions of isometries are the “Killing vector fields”. For basic information on mappings and infinitesimal mappings see Kobayashi and Nomizu {1; v.1, ch.6}, Lichnerowicz {2}, and Yano {3}.

II. Other topics of substantial interest.

(a) *Classical curve and surface theory.* There is still a lot of information to be mined here, though the ore naturally tends to decrease in quality, rapidly passing the point of diminishing returns.

In our discussions of curve theory, we initially sought the limiting circle through 3 points on a plane curve. This osculating circle is often said to have second order contact with the curve. The notion of contact of curves and surfaces is described in Struik {1; 23}, somewhat more carefully in Goetz {1; 37, 44} and Kreyszig {1; 47–51, see especially Theorem 14.3}, and in detail in Favard {1; Part 1, ch.2}. Innocuous as the concept may seem, it is sometimes useful to have precise information about it (cf. do Carmo and Warner [1; pg. 136]).

In the theory of space curves it is natural to seek an “osculating sphere” having third order contact with the curve—see Blaschke {1; v.1, 33}, Eisenhart {2; 37}, Goetz {1; 77}, Kreyszig {1; 51}, Struik {1; 25}, or Gerretsen {1; 91}, which gives the analogous considerations in \mathbb{R}^n . The condition that a curve lie on some sphere is usually determined by setting equal the radii of all osculating spheres. Problem III.4-2 gives a different approach (generalized in Gerretsen {1; 78}); some calculation is required to establish the equivalence of the two answers.

A standard topic in curve theory is the study of involutes and evolutes, which was originated (cf. Coolidge {1; 319}) by Huygens in order to construct a pendu-

lum whose period is independent of its amplitude (for ordinary pendulums this is only approximately so, for small amplitudes). This property is possessed by a

pendulum whose weighted end describes a cycloid, hence the problem of finding a curve whose “involute”, traced out by unwinding a thread from it, will be a cycloid. The desired curve (the “evolute” of the cycloid) turns out to be another cycloid. [Unfortunately, this ingeniously designed Huygens pendulum was superseded by a pendulum suspended from a spring, which turns out to work just as well.] Two other familiar curves might be mentioned here: the evolute of the tractrix is a catenary. The standard material, none too interesting, on involutes and evolutes (which are also defined for space curves) can be found in Eisenhart {2; 43–45}, Gerretsen {1; 83–87}, Goetz {1; 65–70}, Kreyszig {1; 52–54}, Struik {1; 39–41}, and Strubecker {1; v.1, 222–226}. Guggenheimer {1; 35–47} gives a treatment requiring less differentiability, by means of the Riemann-Stieltjes integral (or see Ostrowski [1]), and finds all plane curves similar to their evolutes (pp. 59–61).

It is strange that the theory of envelopes is so seldom mentioned in connection with involutes and evolutes, for the evolute of a plane curve is the envelope of its normals, and thus the locus of the centers of its osculating circles. Even the latter fact is seldom mentioned (cf. Guggenheimer {1; 43–44}). As the figure on pg. II.6 seems to indicate, an osculating circle of a curve separates the parts of the curve with smaller curvature from those with larger curvature. A direct verification may be given (cf. Goetz {1; 84}), but it is even easier to prove a much stronger result, due to Kneser. If c is a curve, parameterized by arclength, with κ nowhere 0, then the curve of centers of the osculating circles is $\gamma(s) = c(s) + \mathbf{n}(s)/\kappa(s)$. The parameter s is not arclength for γ . Instead we have

$$\begin{aligned}\gamma'(s) &= c'(s) + \left(\frac{1}{\kappa}\right)'(s)\mathbf{n}(s) + \frac{1}{\kappa(s)}\mathbf{n}'(s) \\ &= c'(s) + \left(\frac{1}{\kappa}\right)'(s)\mathbf{n}(s) + \frac{1}{\kappa(s)} \cdot (-\kappa(s)c'(s)) \quad \text{by Serret-Frenet} \\ &= \left(\frac{1}{\kappa}\right)'(s)\mathbf{n}(s).\end{aligned}$$

Now κ is not constant on any interval, so if $\kappa' \neq 0$ everywhere, then γ' is not constant on any interval, and hence no portion of γ is a straight line. Therefore

$$|\gamma(s_1) - \gamma(s_2)| < \text{length of } \gamma \text{ from } \gamma(s_1) \text{ to } \gamma(s_2) \\ = \int_{s_1}^{s_2} |\gamma'(t)| dt = \left| \frac{1}{\kappa}(s_2) - \frac{1}{\kappa}(s_1) \right|,$$

where the left side is the distance between the centers of the osculating circles at s_1 and s_2 , while the right side is the difference in the radii of these osculating circles. Hence one must lie inside the other. Thus all the osculating circles are nested (and the smaller ones, containing points of the curve with larger curvature, must lie inside the larger ones). This gives a striking example of a family of curves (the osculating circles) none of which intersect, but which nevertheless have an envelope (the original curve).

There is a beautiful little book of Boltyanskii {1}, unfortunately out of print, which makes the study of envelopes seem very pretty. In differential geometry books, emphasis is usually placed on envelopes of families of surfaces; see Eisenhart {2; 59–65} and Kreyszig {1; 253–263}. There is a fairly thorough treatment of envelopes in Favard {1; Part 1, ch.3}. We should not fail to mention that the conjugate locus of a point is just the envelope of the geodesics through the point (refer again to the picture on pg. IV.221). An argument of Carathéodory shows that the conjugate locus always has at least 4 cusps (cf. Blaschke {1; v.1, 231}). Similar arguments show that the evolute (= envelope of the normals) of a closed plane curve must have at least 4 cusps. This actually follows immediately from the four vertex theorem, but it can also be used to prove the four vertex theorem, as well as a four vertex theorem for the hyperbolic plane (oral communication by A. Weinstein).

Naturally, many special sorts of space curves are investigated in the classical books. Special mention may be made of Bertrand curves—see Blaschke {1; v.1, 35}, Eisenhart {2; 39–41}, Gerretsen {1; 83}, Goetz {1; 74–76}, Haack {1; 29}, or Strubecker {1; v.1, 228–238}. They are of some interest, as they may be used to prove (Catalan's theorem) that the only ruled minimal surface is the helicoid—see do Carmo {1}. (This also follows from a classical result of Schwarz that a minimal surface containing a straight line is taken into itself by a rotation of π around the line. See, for example, Blaschke {1}.) Perhaps this is also a suitable place to mention an elementary theorem of Beltrami: the tangent developable of c intersects the osculating plane of c at $c(t)$ in a curve γ whose curvature at $c(t)$ is $3/4$ the curvature of c at this point.

Moving on to global theorems, we first mention that a simple proof of Theorem II.1-8 can be given when κ is nowhere 0 by noting that the curve is locally

convex, and then using a theorem of Schmidt (cf. Stoker {1; 46–47}) that local convexity implies convexity. (But for this proof we need to know that the curve bounds a region, to which Schmidt's theorem is applied. The proof given previously, using the “Hopf Umlaufsatz” (Theorem II.1-7), not only works for $\kappa \geq 0$ or $\kappa \leq 0$, but also proves directly that the curve lies on one side of each of its tangent lines, a criterion for convexity which does not use the fact that the curve bounds a region.) Schmidt's result holds in all dimensions, and could also be used to prove Hadamard's theorem (Theorem III.2-11) for imbedded surfaces.

Some theorems of Schwarz, Schur, and Schmidt are especially interesting because they are global theorems about non-closed curves—see Blaschke {1; v.1, 61–64}, as well as Chern {3; 35–38}. Guggenheimer {1; 31} proves one of these theorems in the special case where both curves are planar; Hilbert and Cohn-Vossen {1; 211–212} show how to obtain the general case from this, and then give some further discussion. Compare also Blaschke {1; v.1, §39}. Our old friend, the four vertex theorem, can be proved from the planar case (Guggenheimer {1; 30–32} or Fog [1]). By the way, in our proof of the four vertex theorem we only obtained 4 points where $\kappa' = 0$, but it is easy to actually obtain 4 relative maxima or minima of κ . Other interesting global theorems about non-closed curves are due to Vogt and Ostrowski (see Guggenheimer {1; 49–53} or Ostrowski [2]).

Laugwitz {1; 198–202} has some results on curves of constant width, which may also be proved by more elementary means—see, for example, the beautiful book of Yaglom and Boltyanskii {1; ch.7}.

Notice that the formula for τ on pg. III.225 can be written $\tau = (\arctan \kappa_g)'$. It follows from this that $\int \tau ds = 0$ for a closed curve lying on a sphere. Conversely, if this holds for all closed curves on a surface, then the surface is part of a plane or sphere (Scherrer [1]). The same results hold for $\int \kappa^n \tau ds$ (Saban [1]). Finally, we mention that any curve in S^2 is the unit tangent \mathbf{t} of some curve c of constant torsion. Such curves were studied classically (see, for example, Blaschke {1; v.1, 47}, and Darboux {1; §§36, 39 and v.4, Note 7, §7}), but only recently have closed curves of constant torsion been discovered (Weiner [1]; compare pg. IV.110).

Classical surface theory is of course much more extensive, and there is so much material contained in the standard classical books that there is no point trying to list the main topics. In Part B mention is sometimes made of specific information contained in particular books. For serious digging be sure not to forget the *Encyklopädie der Mathematischen Wissenschaften*.

See also the references under III.(c).

(b) *Extremal and isoperimetric problems.* Various extremal and isoperimetric problems for curves are treated in Blaschke {1; v.1, ch.2}. See Chapter 8 of the same volume for surfaces, and Chapters 2 and 6 of the second volume for similar problems in special affine geometry. For various sorts of solutions to the isoperimetric problem see also Blaschke and Reichardt {1; §28}, Chern {3; 25–29}, and Guggenheimer {1}. The last has a solution in the plane (pp. 79–84) which generalizes (pg. 289) to convex surfaces, by means of Steiner's formulas relating the area A and enclosed volume V of a compact convex surface $M \subset \mathbb{R}^3$ to the area $A(\varepsilon)$ and the enclosed volume $V(\varepsilon)$ of its parallel surface $\{p + \varepsilon \nu(p) : p \in M\}$:

$$A(\varepsilon) = A + 2\varepsilon \int_M H \, dA + 4\pi \varepsilon^2$$

$$V(\varepsilon) = V + \varepsilon A + \varepsilon^2 \int_M H \, dA + \frac{4}{3}\pi \varepsilon^3.$$

(The first formula follows from Problem III.3-12, and the second by integrating with respect to ε . It can also be proved by approximating the surface by convex polyhedra. In this case H measures dihedral angles and K measures vertex angles; for more details see pp. 168–170 of the article by Santalo in Chern {3}.) See also Blaschke {3} or Santalo {1} for a treatment of the isoperimetric problem by integral geometry (III.(a)). There is a detailed discussion of the isoperimetric problem in Blaschke {2}, but for the final word (including the isoperimetric problem in the spaces of constant curvature) see Hadwiger {1} and references therein. For later work, see Chavel {2}.

(c) *Closed geodesics.* For brief remarks on the existence of closed geodesics see Blaschke {1; v.1, 211–212}. See also pg. 233 for surfaces on which all geodesics are closed; for more details consult Berger {1}, which also proves the theorem of L. W. Green [1] that the sphere is the only surface on which every point has a unique conjugate point. For modern treatments of closed geodesics see Schwartz {1}, Flaschel and Klingenberg {1}, Besse {1}, and Klingenberg {1}, {2}.

(d) *Holonomy.* The holonomy group of a connection on a principal bundle P with group G is the subgroup of all $a \in G$ such that a fixed $u \in P$ can be joined to $u \cdot a$ by a horizontal curve. Thus, the holonomy group measures the extent to which the distribution of horizontal subspaces is not integrable. [In classical mechanics (V.(a)) a system of “constraints” which can be described by a suitable distribution is called “holonomic” if the distribution is integrable, and “non-holonomic” otherwise. Thus, the “holonomy group” really should be called the “non-holonomy group”, since it measures the extent to which a distribution is non-integrable.] Holonomy groups are studied in great detail in Kobayashi

and Nomizu {1}, with basic properties treated in chapter 2 of volume 1, and applications throughout. In particular, we have the “holonomy theorem” of Ambrose and Singer (first proved, or at least stated, by É. Cartan), which describes the Lie algebra of the holonomy group in terms of the curvature form of the connection. It should perhaps be pointed out that this is in some sense a global version of a classical description of the curvature tensor in terms of parallel translation around an “infinitesimal parallelogram”—see Eisenhart {1; 65}, Kreyszig {1; 295}, or Laugwitz {1; 108}, or slightly different versions in Bishop and Crittendon {1; 97}, Nelson {1; 77}, or Singer and Thorpe {1; 170–174}. It should also be noted that the holonomy theorem gives an immediate proof of the Test Case. The most important application of holonomy groups for Riemannian manifolds is the de Rham decomposition theorem (Kobayashi and Nomizu {1; v.1, 187 ff.}).

(e) *Reducing the group of a bundle; G -structures.* The proof of the holonomy theorem uses the concept of a reduction of the group G of a principal bundle P to a subgroup H . This is, by definition, a subset P' of P such that $u \cdot a \in P'$ for all $u \in P'$ and $a \in H$, so that P' is a principal bundle with group H . The prime example is a reduction of the group $GL(n, \mathbb{R})$ of the bundle of frames of M to the subgroup $O(n)$. Any Riemannian metric $\langle \cdot, \cdot \rangle$ gives such a reduction—we define P' to be the set of all frames which are orthonormal with respect to $\langle \cdot, \cdot \rangle$. Conversely, given any such reduction, we can define $\langle \cdot, \cdot \rangle$ by declaring the frames in P' to be orthonormal. Similarly, an orientation on M is equivalent to a reduction of the group $GL(n, \mathbb{R})$ to the group $GL^+(n, \mathbb{R})$ of matrices of positive determinant. It could hardly be supposed that mathematicians would not get around to generalizing these examples: a reduction of the bundle of frames on M to a subgroup $G \subset GL(n, \mathbb{R})$ is called a **G -structure**. For the theory of G -structures see the last chapter of Sternberg {1}, and Kobayashi {1}.

(f) *Contact transformations and contact structures.* At each point p of M we can consider the set of $(n - 1)$ -dimensional subspaces of the tangent space M_p . With the notation of Chapter V.13, this set would be denoted by $G_{n-1}(M_p)$; in the terminology of topic III.(g) it is the set of 1st order $(n - 1)$ -dimensional contact elements at p . We can form the manifold $C_{n-1}^1 M = \bigcup_{p \in M} G_{n-1}(M_p)$ of all these contact elements, and any immersion $f: M \rightarrow N$ gives rise to a map $f_*: C_{n-1}^1 M \rightarrow C_{n-1}^1 N$. An arbitrary smooth map $g: C_{n-1}^1 M \rightarrow C_{n-1}^1 N$ was classically called a **contact transformation** if it satisfies the following condition, which is automatic for f_* : for every hypersurface $P \subset M$, there is a hypersurface $Q \subset N$ such that the set of tangent spaces of Q is just the image under g of the set of tangent spaces of P . This geometric definition is unfortunately rather vague, since we want to allow the possibility, for example, that Q is a

single point $q \in N$ and g takes all tangent spaces of P into $G_{n-1}(N_q)$. But it is not hard to derive a precise analytic condition which captures the geometric content. The manifold $C_1^1\mathbb{R}^2$, for example, has a covering by two coordinate systems, one of which is defined on the set U of all directions not parallel to the y -axis—we use the coordinates a, b of the point $p \in \mathbb{R}^2$ as two coordinates on U and the slope m of the line in \mathbb{R}^2_p as the third coordinate. For a curve c in \mathbb{R}^2 we have

$$m(\text{subspace spanned by } c'(t)) = \frac{db(c'(t))}{da(c'(t))}.$$

From this it is not hard to see that a map $g: U \rightarrow U$ should be called a contact transformation if and only if $g^*(db - m da) = \alpha(db - m da)$ for a nowhere 0 function α . For $C_n^1\mathbb{R}^{n+1}$, with x^1, \dots, x^n, z as coordinates for the point, and y^i ($i = 1, \dots, n$) as the slope of the intersection of the n -dimensional subspace with the (x^i, z) -plane, we have the analogous criterion, in terms of the form $dz - \sum_i y^i dx^i$. For arbitrary manifolds these conditions can be formulated on coordinate neighborhoods. Although the classical reference Lie and Scheffers {2} will present problems, it is delightfully concrete and filled with examples; see also Eisenhart {4; ch.6} and Favard {1; part 1, ch.4}.

Nowadays, these motivating geometric considerations are almost never mentioned (an exception is Hermann {2; ch.3}). The modern approach to the subject may be found in Kobayashi and Nomizu {1; v.2, 381–382} and Kobayashi {1; 28 ff.}; it involves the notion of a **contact structure**, which also plays an important role in classical mechanics (V.(a)). An important tool in the study of contact structures is a theorem of Darboux, which is proved in Kobayashi {1; Appendix 1}; a very different proof is given in Lang {1; ch.5, §7}. The proof in Godbillion {1; 115–121} or Sternberg {1; 135–141} is of interest, as it uses the “characteristic system” of an ideal of differential forms. This “characteristic system” is related to the characteristics of a PDE; to see this made more explicit one may consult Dieudonné {1; v.4, 92–118}. The “Legendre transformation” is a contact transformation which is often used in PDE’s (see, for example, Courant and Hilbert {1; v.2, 32–29}). Legendre transformations are also used in the calculus of variations and classical mechanics (cf. Abraham {1}, Godbillion {1}, or Sternberg {1}). For the connection between the two, try Hermann {2; ch.6, §9}.

We could also consider maps $g: C_r^k M \rightarrow C_r^k N$, defined on k^{th} order r -dimensional contact elements [cf. III.(g)], satisfying an analogous geometric condition. But these are essentially of the form f_* for $r < n - 1$, or an extension of a contact transformation $g: C_{n-1}^1 M \rightarrow C_{n-1}^1 N$ for $r = n - 1$.

(Knebelman [1]). Similarly, one can define “infinitesimal contact transformations”, but they always come from a map $f: M \rightarrow N$. See Eisenhart {4; 252} or Lie and Scheffers {2; ch.4, §2} for a classical statement of this fact, and Kobayashi {1; 30} for a modern version.

(g) *The Laplacian and Hodge theory*. Berger, Gauduchon, and Mazet {1} is an excellent introduction to the significance of the Laplacian, though somewhat out of date because of the recent rapid progress in this field. For many applications of Hodge theory similar to Bochner’s Theorem (Theorem IV.7-63), see Yano and Bochner {1}, and Yano {1} (which also has applications of integral formulas similar to those in Chapter V.12). See also Ruse, Walker, and Wilmore {1}, and Jost {1}. A simple application to prove Poincaré duality is given in Warner {1}; for applications to complex manifolds see, for example, Weil {1}.

III. Other geometries

(a) *Finsler geometry*. For a brief introduction, see Laugwitz {1; §15}. For an extended treatment see Rund {1} and Matsumoto {1}. The reprinting of the thesis of Finsler {1}, with a bibliography up to that time, may be of interest.

(b) *Integral geometry*. Blaschke {3} and Santalo {1} are very nice introductions to this subject. The article by Santalo in Chern {3} gives references to later work. It is of interest to compare the arguments on pg. 167 with the proofs of Fenchel’s theorem and the Fary-Milnor theorem on pp. 33–35.

(c) *Line geometry*. Here one studies the manifold consisting of all lines in \mathbb{R}^3 . I haven’t the slightest idea what is done, but there are supposed to be some nice things. See Blaschke {1; v.1, ch.9}, Eisenhart {2; ch.12}, Favard {1; pt.2, sec.1, ch.5}, Forsyth {1; ch.12} and Hlavatý {2}. See also (e). The manifold of all circles in \mathbb{R}^3 has also been studied. See Eisenhart {2; ch.13} and Forsyth {1; ch.12}.

(d) *Affine geometry*. For special affine curve theory see Blaschke {1; v.2} and Favard {1; pt.2, sec.2, ch.1}, as well as Guggenheimer {1; §8-3}. For special affine surface theory see Blaschke {1; v.2} and Favard {1; pt.2, sec.2, ch.2}. See also Flanders [1] and the references listed under it. Not much seems to have been written about general affine invariants. See Guggenheimer {1; ch.7-3, probs.10–12} and Dieudonné {1; v.4, ch.20, §14, probs.11, 12}, which first describes an affine normal (“pseudo-normale”) for a hypersurface of any manifold with a torsion-free connection on its bundle of frames [compare with the second part of (e)] and then specializes to special affine geometry of \mathbb{R}^n (it will probably make things much easier to rewrite the problem so that it deals with moving frames, rather than with the bundle of frames itself). On the other hand, there

is a considerable literature on what might be called “general linear geometry”—properties of submanifolds of \mathbb{R}^n invariant under all linear maps (but not translations!), as well as properties invariant under all elements of $SL(n, \mathbb{R})$, again excluding translations [this certainly seems like a strange geometry to study, but see Laugwitz {2}]. See Salkowski {1}, Shirokow and Shirokow {1}, and Nomizu and Sasaki {1}.

(e) *Projective differential geometry*. This is the study of properties of submanifolds of projective space \mathbb{P}^n which are invariant under the projective group (cf. Harts-horne {1} for basic terminology). An eminent differential geometer, who perhaps prefers to remain anonymous, has said that the problem with projective differential geometry is that the projective group is too large to allow any interesting local results, while no one has ever discovered any interesting global ones.

The best introduction is probably Fubini and Čech {1}, which also introduces É. Cartan’s methods (using moving frames—compare (g)) as worked out in Cartan {5}. Other texts are Bol {1}, Favard {1; pt.2, sec.3}, Lane {1}, Akivis and Goldberg {1}, and Wilczynski {1}, one of the earliest works in the field [cf. (g)]. For “line geometry” in the projective case see Švec {1}.

Just as Riemannian geometry generalizes the differential geometry of \mathbb{R}^n , so one might expect to generalize projective differential geometry to an arbitrary manifold M by forming the union of the projective spaces obtained from each tangent space M_p , constructing a corresponding principal bundle P , and considering some canonical connection ω on P . All these steps can be carried out, but ω is not characterized so simply as in the Riemannian case by having vanishing torsion (which is defined only for connections on the bundle of frames); instead, there is a unique ω which satisfies certain identities like the Bianchi identities. This is described in Cartan {5}, but it will probably be much easier to read Kobayashi {1; 127–138}.

(f) *Other esoteric geometries*. See Blaschke {1; v.3} for the interesting, but complicated, geometries of Möbius, Laguerre, and Lie; for the last of these, see also Cecil {1}. In all three geometries, the points are basically the circles in the plane, or the spheres in space, etc., and properties are sought which are invariant under various groups of maps on these circles or spheres. Möbius geometry involves those maps which take the set of all circles or spheres through a fixed point into another set of the same sort. Such maps are always induced by similarities and inversions in the plane, space, etc., so that Möbius geometry reduces to the study of this group of maps (the Möbius group) on these spaces. For dimensions $n > 2$ it is thus “conformal geometry”.

In the case of the plane one might also study properties of curves invariant under all analytic maps. I know of only one strange result in this direction—see Theorem 1-4 of Ahlfors {1}.

The more complicated geometries of Laguerre and Lie are allied to the notion of contact transformations (II. (f)). Laguerre geometry involves the maps which take a set of circles tangent to a line (or of spheres tangent to a plane) into another set of this sort, while the geometry of Lie involves the group of maps which simply take circles or spheres which are tangent to each other to pairs of the same sort.

Another weird topic is the theory of webs—see Blaschke {4} and Blaschke and Bol {1}.

All sorts of other oddities may be found by consulting *Mathematical Reviews* and the journal *Tensor*.

(g) *Lie's theory of differential invariants, and É. Cartan's general method of moving frames.* Lie's theory is the one topic which I greatly regret not having written up, for it is used extensively in certain early work which is far more impenetrable than other classical material. In particular, Lie's theory was used in the first investigations of special affine surface theory by Pick [1] and in early work in projective differential geometry (cf. Wilczynski {1}). Unfortunately, a reasonable exposition would probably require close to a hundred pages, which wouldn't fit in anywhere, for the material on first order linear PDE's from Chapter V.10 is needed, while the theory relates most directly to Chapter III.2 (which is already too long). Matters were in no way helped by my lack of understanding, nor, since this delayed its treatment until last, by my lack of endurance.

The most interesting part of Lie's theory applies to situations like Euclidean, special affine, or projective differential geometry, where we seek properties of submanifolds of M which are invariant under a group G of diffeomorphisms [i.e., submanifolds of homogeneous spaces (I. (b))]. The idea is to find “(geometric) differential invariants of order k for r -dimensional submanifolds of M ”, a simple example of which is the curvature κ of a curve c in \mathbb{R}^n . This is an “invariant” (it is the same for a curve and its composition with a Euclidean motion) “of order 2” (one can compute it at any point knowing only the first two derivatives of the curve at that point) which is independent of the parameterization (“geometric”).

Such invariants can be thought of as functions on a suitable space. First we construct the “ k -jets” of maps of $(\mathbb{R}^r, 0)$ into (M, p) ; these are equivalence classes $j_0^k(f)$ of maps $f: (\mathbb{R}^r, 0) \rightarrow (M, p)$, where $f \sim g$ if all mixed partials of order $\leq k$ of all component functions of f and g are equal at 0 (cf. topic VI. (c)). On the set of k -jets represented by immersions $f: (\mathbb{R}^r, 0) \rightarrow (M, p)$

we introduce a further equivalence relation by declaring $j_0^k(f_1)$ and $j_0^k(f_2)$ equivalent if in a neighborhood of $0 \in \mathbb{R}^r$ we have $f_2 = f_1 \circ \alpha$ for some diffeomorphism α . These new equivalence classes are the k^{th} order r -dimensional **contact elements** of M at p (for $k = 1$ they may be identified with the r -dimensional subspaces of M_p). The set $C_r^k M$ of all such contact elements at all $p \in M$ is a manifold, and any diffeomorphism $\phi: M \rightarrow M$ gives rise to a diffeomorphism $\phi_*: C_r^k M \rightarrow C_r^k M$. A geometric differential invariant of order k for r -dimensional submanifolds of M under a group of diffeomorphisms G is just a function $F: C_r^k M \rightarrow \mathbb{R}$ invariant under G (i.e., satisfying $F \circ \phi_* = F$ for all $\phi \in G$). This set-up is briefly discussed in Hermann {2; ch.3, §14}.

We can also consider “differential invariant tensors”. If γ is a k^{th} order r -dimensional contact element of M at p , represented by a k -jet $j_0^k(f)$ for $f: (\mathbb{R}^r, 0) \rightarrow (M, p)$, then the 1st order r -dimensional contact element represented by the 1-jet $j_0^1(f)$ depends only on γ —it may be thought of as the “tangent space” $T\gamma$ of γ . A function F on $C_r^k M$ such that each $F(\gamma)$ is a bilinear function $F(\gamma): T\gamma \times T\gamma \rightarrow \mathbb{R}$, for example, may be thought of as a k^{th} order covariant tensor of order 2 for r -dimensional submanifolds of M ; it is easy to formulate the invariance conditions for such F .

There is actually a reasonable way to compute such differential invariants, or at least to formulate the computations (in practice they become hopeless quite quickly unless one introduces some extraneous geometric insight). Any $X \in \mathfrak{g} =$ Lie algebra of G induces a 1-parameter family of diffeomorphisms $\{\exp tX\}$ of M , hence a family $\{(\exp tX)_*\}$ on $C_r^k M$, and hence a vector field $X^{(k)}$ on $C_r^k M$. If G is connected, and thus generated by the elements $\exp tX_i$ for a basis $\{X_i\}$ of \mathfrak{g} , then F is invariant if and only if $X_i^{(k)}(F) = 0$ for all i ; each of these equations is simply a linear first order PDE in terms of coordinates on $C_r^k M$. This allows one to compute the invariants F once one picks a natural coordinate system on $C_r^k M$ and figures out appropriate methods for evaluating $X_i^{(k)}(\rho)$ for each coordinate function ρ . There is no difficulty solving each particular equation $X_i^{(k)}F = 0$, by the methods of Chapter V.10, §1. We find that F must be constant along certain curves in $C_r^k M$, or equivalently, that F must be expressible as a function of certain combinations of the coordinate functions. The problems arise when we seek a solution F of the equations $X_i^{(k)}F = 0$ for all i ; we then have to guess a single function which can be expressed as a function of each of the different combinations of coordinate functions which arise for each i .

Even without performing the calculations, however, one can decide how many invariants there should be. We seek a submanifold $\mathcal{P} \subset C_r^k M$ which intersects

each “orbit” $\{\phi_*\gamma : \phi \in G\}$, $\gamma \in C_r^k M$ just once. The invariant functions on $C_r^k M$ are in one-one correspondence with the functions on \mathcal{P} , so the number of “independent” ones is the dimension of \mathcal{P} , thus the dimension of $C_r^k M$ minus the dimension of an orbit. Differential invariant tensors can be treated similarly.

Unfortunately, there is no really good reference for this topic. One can try Lie and Scheffers {1; ch.22}, but it will be much easier to read Scheffers {1}. Plane curves are treated in volume 1, part 1, §§8, 9; space curves in volume 1, part 2, §12; and surfaces in volume 2, part 3, §10. All the information here will be quite new, because curves and surfaces are determined up to congruence by certain *functions*, not by tensors; for curve theory this means that no use is made of the parameterization by arclength (which is really equivalent to using the first fundamental form of the image curve). There are also some (rather misleading) calculations in volume 2, part 3, §6 which essentially determine all invariants on the space of jets (i.e., the functions on surfaces which are invariant under Euclidean motions but *not* under change of parameter). The main problem with this reference is that it doesn’t illustrate the general methods of computation outlined above.

The most modern reference for these methods, Guggenheimer {1; ch.7-2}, is frustratingly old-fashioned in its language. It might help to mention that the formally introduced new “variables” $x'_i = dx_i/dx_1, x''_i, \dots$ are merely certain natural coordinates for 1-dimensional contact elements in \mathbb{R}^m : on the set of 1-dimensional contact elements γ represented by curves whose images can be parameterized as $x_1 \mapsto (x_1, f_2(x_1), \dots, f_m(x_1))$ [for unique f_2, \dots, f_m] we let $x'_i(\gamma) = f'_i$, etc. Similarly, on the set of 2-dimensional contact elements γ in \mathbb{R}^3 which are represented by immersions of \mathbb{R}^2 whose images can be parameterized as $(x_1, x_2) \mapsto (x_1, x_2, f(x_1, x_2))$ we have the coordinates $p(\gamma) = \partial f / \partial x, q(\gamma) = \partial f / \partial y, r(\gamma) = \partial^2 f / \partial x^2$, etc. Beware of misprints in some of the computations of the “prolongations”.

There are extensive calculations in Forsythe {1; §§132–146}, but they are not carried out directly on the contact elements. Instead, “relative invariants of order w ” are computed first; these are functions F on the jets such that

$$F(j_0^k(f \circ \alpha)) = (\det \alpha)^w F(j_0^k(f))$$

for any diffeomorphism α . Clearly the product of relative invariants whose weights add up to 0 will give invariants on the contact elements. (Similar tricks are used in the works of Pick and Wilczynski quoted above, as well as in the much more straightforward calculations in Blaschke {1; v.3}.) One may also try the introductory chapter of Schirokow and Schirokow {1}.

Lie's methods are supposedly applicable, in ways I don't understand at all, to such problems as the equivalence of Riemannian manifolds, and even more general questions. See Lie and Scheffers {1; ch.23}, Veblen {1; ch.3, §§20–22, ch.5, 6}, and Wright {1}. It might also be mentioned that there is a theory involving even more general notions than jets and contact elements, the “geometric objects”—see Yano {3; ch.2} or Aczél and Gołab {1}.

É. Cartan's general method of moving frames is a sort of dual to Lie's method which allows computations to be made more easily. The general features of the theory are well illustrated by the development of special affine surface theory in Chapter III.2—see especially pg. III.102. We consider moving frames X_1, X_2, X_3 along $M^2 \subset \mathbb{R}^3$ with $\det(X_1, X_2, X_3) = 1$. An arbitrary moving frame of this sort is what Cartan calls a “zeroth order frame”. A “first order frame” is one which is adapted to M (i.e., X_1, X_2 are tangent to M). To define “second order frames” we now try to specialize the first order frames as much as possible by seeking an appropriate condition on the dual and connection forms. As we observed on pg. III.82ff., the condition $\psi_i^3 = \theta^i$ has just the “invariant” property we need—it depends only on the value of the frame at p [i.e., if X_1, X_2, X_3 and $\bar{X}_1, \bar{X}_2, \bar{X}_3$ are adapted moving frames with dual and connection forms θ^i, ψ_j^i and $\bar{\theta}^i, \bar{\psi}_j^i$, respectively, and the two frames agree at p , then $\psi_i^3(p) = \theta^i(p)$ if and only if $\bar{\psi}_i^3(p) = \bar{\theta}^i(p)$].

This definition of second order frames already gives an invariant tensor, the special affine first fundamental form. To obtain this specialization we used the calculations on pp.III.79–81. To be sure, these calculations were not very difficult, but that is because we already knew what we were looking for; we didn't even bother to compute the ψ_j^i in general, since they would not be involved in our invariant condition. It would have been much harder to simply guess an invariant condition without the previous geometric motivation (indeed, the difficulties which arise here are exactly dual to the problem in Lie's method of finding a common solution to the equations $X_i^{(k)} F = 0$); this is an aspect of the theory which Cartan always carefully suppressed in his expositions of it.

Now we can seek “third order frames” by specializing the second order frames. An appropriate condition is $\psi_3^3 = 0$; it gives us the special affine normal. The verification that this condition is invariant is given on pp. III.102–103. It would clearly be a lot easier to discover *ab initio* than the corresponding invariant condition (pg. III.100) for first order frames; in general, one always works with the highest order frames already successfully discovered. Specializing the third order frames would lead us to the special affine second fundamental form (X_1 and X_2 would be the eigenvectors of $\mathbf{\Pi}$ with respect to \mathbf{I}). For more examples and details, see Cartan {6} or Favard {1}.

IV. The Russian school; synthetic differential geometry

A thorough treatment of the foundations of surface theory without differentiability hypotheses is given in Alexandrov {1}. As an introduction, the reader may prefer to consult Busemann {1} or relevant portions of Efimov {1} and Pogorelov {1}, {2}, {3}. For an extensive connected account of further developments in the theory see Pogorelov {5}. We might also mention Pogorelov {6}, where the geometric results are used to obtain stronger-than-usual results about PDE's.

Although most of the material in these references pertains to convex surfaces (for which one may also consult Bonneson and Fenchel {1}, Blaschke {2}, Hadwiger {1}, and Yaglom and Boltyanskii {1}), there is also an elaborate theory which investigates the most general sorts of surfaces, or even arbitrary metric spaces. One treatment can be found in Alexandrov and Zalgaller {1}, while a somewhat different direction is taken in Blumenthal {1}, Blumenthal and Menger {1}, and Rinow {1}. In yet another vein, we have the work of Busemann, which represents the very antithesis of Riemann's approach (whereby a mechanism for measuring lengths of arbitrary curves is postulated, and geodesics are defined as curves of minimal length). In Busemann {3} postulates are instead given for the geodesics, and many relations of classical differential geometry are derived from them; although the arguments are often involved, just as a rigorous axiomatic development of Euclidean geometry would be, the strength of the results is often startling. For related results see Busemann {2}.

V. Applications to physics

(a) *Classical mechanics*. It turns out that differential geometry provides the natural language for classical mechanics, for the two equivalent basic formulations of the subject, via Lagrange's equations and Hamilton's equations, take place on the tangent bundle and cotangent bundle, respectively, of a suitable manifold. A discussion of mechanics which manages to make some interesting points in a short space, but which doesn't make very clear which manifold one is working on, may be found in Laugwitz {1: §14}. Another brief discussion, without this shortcoming, is contained in Bishop and Goldberg {1: ch.6}. One can consult pp. 141–147 of Sternberg {1}, which also mentions other aspects of the subject as part of an extensive discussion of the calculus of variations, in the succeeding chapter. Similarly, see Hermann {1: ch.16}. The short book by Godbillon {1} reaches its climax in the final, 9 page, chapter on mechanics, which begins by defining a "mechanical system" as a triple (M, T, π) , where M is a manifold, T a differentiable function on TM , and π a semi-basic form on TM . A serious study of mechanics will be found in Abraham {1}, beginning in the third chap-

ter, where it is admitted however, that the treatment “possibly . . . will seem severely unmotivated without some background in classical mechanics . . .”; see also Wasserman {1}. Aside from this difficulty, common to all these books, the most heartbreaking omission is any adequate discussion of the fictional “forces of constraint” which are involved in such useful abstractions as “rigid bodies”. These can usually be formulated as particular subspaces that the velocity vector in \mathbb{R}^{3N} of the system of N particles is constrained to lie in. When these subspaces form an integrable distribution (the constraints are “holonomic”) the integral submanifolds form a lower dimensional “configuration space” and the basic principle is that the motion of the system with these forces of constraint is determined by restricting the original equations on $T\mathbb{R}^{3N}$ or $T^*\mathbb{R}^{3N}$ to equations on the tangent or cotangent bundle of the configuration space. (Some details are given in Hermann {2; ch.2}.) For physics books on classical mechanics the following references may be of use: Corbin and Stehle {1} (the most modern in spirit of the elementary books), Pars {1}, and Whittaker {1}.

(b) *General Relativity*. Fortunately, I was ultimately not foolish enough to attempt writing anything on this vast subject which I do not understand. My conscience is set at ease by recommending the monumental book of Misner, Thorne, and Wheeler {1}, which is probably owned by every relativist in the world. For more mathematical treatments you may prefer Sacks and Wu {1}, which places great emphasis on foundational points, Weinberg {1}, Hawking and Ellis {1}, O’Neill {2}, and Beem {1}.

VI. Miscellaneous

(a) *Calculus of variations; Hamilton-Jacobi theory*. A subject closely linked with mechanics (V.(a)). The two great classical works usually referred to are Carathéodory {1} and É. Cartan {4}. See also Abraham {1}, H. Cartan {1}, Godbillion {1}, Hermann {1; pt.2}, Rund {2}, and Sternberg {1; ch.4}.

(b) *Sprays*. This is a topic which I have assiduously avoided learning, convinced that one can get by without it, and suspicious that it’s just a complicated new way of saying something old. Less obstinate readers may wish to consult Gromoll, Klingenberg, and Meyer {1; 60}, Lang {1; ch.4, §§3–5, ch.6, §6}, or Sternberg {1; 199, 361}.

(c) *Jets*. These, and the contact elements [cf. III.(g)], are natural structures to consider in differential geometry, but they are only just beginning to be used in any serious way. For basic definitions, see Bourbaki {1; §12} or Dieudonné {1; v:3 (ch.16.5–Problem 9, ch.16.9–Problem 1), v:4 (ch.20.1–Problem 3)}. For some applications, see Kobayashi {1; 139ff.}.

(d) *Other definitions of connections.* Gromoll, Klingenberg, and Meyer {1; 43} gives a definition of a connection in terms of a map $K: TTM \rightarrow TM$. This is useful in dealing with infinite dimensional manifolds; see Flaschel and Klingenberg {1; ch.1}. Connections have also been defined as sprays with certain properties, and as a splitting of the “jet exact sequence”. I personally feel that the next person to propose a new definition of a connection should be summarily executed.

(e) *Reducing differentiability hypotheses.* It is of some interest to some people (analysts) to establish results with the minimum differentiability assumptions. Although the work of the Russian school sometimes eclipses such efforts, this is not always true, and in any case few mathematicians seem to find it a sufficiently compelling argument to go that route. In any proof of classical geometry one can always carefully count how many times one differentiates, but this usually turns out to be one or two more times than one really has to, if one is sufficiently clever. So the problem of finding minimal differentiability hypotheses (and examples to prove they are minimal) is not easy. A long series of papers on this subject was published by Hartmann and Wintner, mainly in the *American Journal of Mathematics*, beginning in 1947.

(f) *Transversality.* Not a part of differential geometry, really, but of differential topology. Nevertheless, it is probably a wise move to learn the basic ideas. See Sternberg {1; 64ff.} or Guillemin and Pollack {1}, with its many beautiful applications.

(g) *Polyhedral geometry, models, constructive aspects, etc.* Perhaps the oldest contribution in this direction was the argument of Hilbert and Cohn-Vossen {1; pp. 194–195} proving Gauss’ Theorema Egregium for polyhedral surfaces. Recent work of T. Banchoff and others has carried this approach much further. One may also consult Sauer {1} and Kruppa {1}. For a rather different approach to the Gauss-Bonnet-Chern Theorem, see Palais {1}.

B. BOOKS

During the compilation of this bibliography, certain instincts urged me to seek encyclopaedic completeness, while healthier ones advised selectivity and utility. From this conflict resulted the usual unsatisfactory compromise, wherein the advantages of neither course of action is retained. I have tried to single out sources which might be particularly valuable, but this applies mainly to books concerned with the topics covered in these five volumes; many others will have already been mentioned in Part A.

Encyklopädia der Mathematischen Wissenschaften, Volume III, Part 3D, B. G. Teubner, Leipzig, 1902–1927.

Abraham, R. and Marsden, J.

Auslander, L.

- {1} *Differential Geometry*, Harper & Row, New York, 1967 (MR 35, #2208).

This is an attempt to construct an introductory course in differential geometry from the point of view of Lie groups, with the fundamental equations of surface theory arising from the equations of structure of $SO(3)$. Later chapters cover Riemannian geometry. The treatment of geodesic completeness (pp. 203–214) may be of interest, and the Poincaré upper half-space is discussed in some detail (pp. 223–236). In particular, there is a description of the various one-parameter subgroups of the group of isometries. The orbits of these subgroups are the geodesics, geodesic circles, horocycles, and equidistant curves (for these are the curves of constant curvature).

Auslander, L. and MacKenzie, R. E.

Berger, M. and Gostiaux, B.

- {1} *Géométrie Différentielle*, Armand Colin, Paris, 1972 (MR 58 #13102)

A very beautiful recent text on differentiable manifolds, with some differential geometry included. §§6.7–6.9 and 7.5 prove the Gauss-Bonnet

theorem for submanifolds of Euclidean space by the method of Allendoerfer and Fenchel mentioned at the beginning of Chapter 13 (pg. V.264). Chapter 9 treats global properties of curves, including an elementary proof of the Jordan curve theorem for smooth curves, Whitney's theorem on smooth homotopy of closed curves, and the formula of Fabricius-Bjerre-Halpern, which relates the number of double points and inflection points of a closed curve to the number of double tangents (lines tangent to the curve at two different points).

The next reference is a new edition, with additional material.

- {2} *Géométrie Différentielle: variétés, courbes et surfaces*, Presses Universitaires de France, Paris, 1987 (MR 89b:53001).

There is also an English translation:

Differential Geometry: manifolds, curves, and surfaces, Springer-Verlag, New York-Boston, 1988 (MR 88h:53001).

Besse, A. L.

- {1} *Manifolds All of Whose Geodesics are Closed*, Springer-Verlag, New York, 1978 (MR 80c:53044).

Bianchi, L.

- {1} *Vorlesungen über Differentialgeometrie*, B. G. Teubner, Leipzig, 1899.

This is a translation, with some additions, of the first edition of the original Italian work. Naturally it contains a considerable number of results from classical surface theory, but it differs from many classical books by also treating surfaces in the spaces of constant curvature. See in particular §348, which considers a surface M in the upper half-space model of H^3 . For $p \in (x, y)$ -plane, let γ be the geodesic intersecting M orthogonally and approaching p , and let $f(p)$ be the other point in the (x, y) -plane which γ approaches. Then f is holomorphic if and only if M has (intrinsic) curvature 0. Also note that §110 gives a nicer treatment of the problem considered on pp. V.217–218; Bianchi shows directly that the curve $t \mapsto (u(t, 0), v(t, 0), w(t, 0))$ has the same curvature and torsion as c . (The whole problem is simply ignored by Darboux {1}. By the way, there is no adequate treatment anywhere in the classical literature of the case where $\kappa = \tilde{\kappa}_g$.)

There is a later, 4 volume, Italian edition, not translated, which treats special questions of surface theory in great detail.

Bishop, R. L. and Crittenden, R. J.

{1} *Geometry of Manifolds*, Academic Press, New York, 1964 (MR 29 #6401).

Very compactly written, with many results merely quoted or left as exercises. Particular attention may be called to some of the problems on pp. 106–107, 110, 114, 134. There is a study of complete simply-connected manifolds of constant curvature (§9.5) rather different from the elementary one outlined in Problem III.1-5, a more elaborate study of convex neighborhoods, using the second variation (§11.8), and some applications of the second variation to theorems on the volumes of balls (pp. 256–257). A bibliography of 95 items.

Bishop, R. L. and Goldberg, S. I.

{1} *Tensor Analysis on Manifolds*, Macmillan, New York, 1968 (MR 36 #7057).

Blaschke, W.

{1} *Differential Geometrie*, Volumes 1, 2, Chelsea, New York, 1967; Volume 3, Springer, Berlin, 1929.

Although this book is quite old-fashioned, I nevertheless find it very stimulating, perhaps because the author is more interested in genuine geometric questions, especially global ones, than in the formalities of calculations. More topics are covered here than in almost any other classical book, and there is an extraordinary number of interesting exercises, remarks, and sidelights.

Volume 1, §72 shows that if the geodesic circles are the same as the curves of constant κ_g , then K is constant, while §84 proves the more difficult result (mentioned on pg. IV.309) that K is constant if all curves of constant κ_g are closed. The manipulations of §94 (used in the next section for a proof of Christoffel's theorem) are mysterious; Problem III.3-8 may be used instead. See also the funny result on pg. 121. It is interesting to find that the general formula for variation of area was already given by Gauss (§109). Classical results of Schwarz (one mentioned under topic II.(a)) are given in §§110, 111, while §116 gives the second variation of area (in a special case), and mentions a classical condition of Schwarz for a minimal surface to be a local minimum for area. For a modern presentation, see Barbosa and do Carmo [1]. The proof of the related Theorem IV.9-39 is from Rado {1}. §117 gives the first variation of H and K (we essentially found the first variation of H in order to find the second variation of area). Problem 2 in §118 mentions interesting properties of associated minimal surfaces, for example, the tangent planes at corresponding points are parallel. Conversely, if there is an isometry between two surfaces such that tangent planes are parallel, then they are

either congruent surfaces or associated minimal surfaces (to be taken with a grain of salt—one of the surfaces could be the union, along a common curve, of a piece congruent to part of the other surface and another piece associated to a part of the other surface which is a minimal surface).

Volume 2 covers affine differential geometry. There are very many nice geometric interpretations of the invariants arising here, as well as many global results.

For Volume 3 see topic III.(f).

Bourbaki is the originator of that famous pedagogical method whereby one begins with the general and proceeds to the particular only after the student is too confused to understand even that any more. His influence is to be seen everywhere, probably in these volumes too. Bourbaki has apparently decided that the theory of manifolds has now entered that domain of “dead” mathematics to which he hopes to give definitive form. In this summary of results the corpse is laid out to public view; the complete autopsy is eagerly awaited.

Efimov, N. W.

- {1} *Flächenverbiegung im Grossen*, mit einem Nachtrag von E. Rembs und K. P. Grotemeyer, Akademie-Verlag, Berlin, 1957 (MR 19 59).

A wonderful review article, covering many different aspects of rigidity, with additions by E. Rembs and K. P. Grotemeyer on more recent (but usually rather specialized) results which just double the size of the original. In addition to providing an introduction to the methods of A. D. Alexandrov, there are descriptions of the work of H. Lewy, Liebmann, Cohn-Vossen, etc., which cannot be found collected together anywhere else. I'm afraid, however, that the purported proof of Satz X on pg. 177 is invalid—the mistake appears at the very last step; only Pogorelov's difficult proof (for the more general situation) is available for this result.

The original article also appears in the A.M.S. Translations, series 1, volume 6.

Ehrlich, P. E.

see Beem, J. K.

Eisenhart, L. P.

- {1} *Riemannian Geometry*. Princeton University Press. Princeton, N.J., 1966 (MR 11 687g).

As good a compendium as any of the basic material of Riemannian geometry. In addition to isometric correspondence, conformal correspondence is also allotted an important role. (However, the discussion of the conformal tensor (§28) is treated better in Gerretsen {1}.) The important classical notion of "scalar curvature" is defined on pg. 83. Appendix 3 gives the form of the metric in normal coordinates, and Appendix 22

gives the surprising result that the Codazzi-Mainardi equations follow from the Gauss equations for “general” hypersurfaces of \mathbb{R}^n , $n \geq 4$. Apart from this, you might like to look at the theorems on pp. 124, 155, 179, 182, 183, 184, 199.

- {2} *A Treatise on the Differential Geometry of Curves and Surfaces*, Dover, New York, 1960 (MR 22 #5936).

This is a subset of Darboux, though it uses classical calculations rather than the moving frames which Darboux introduced for surface theory. A good way to get into more esoteric aspects of surface theory. Many results given in the problems.

- {3} *Non-Riemannian Geometry*, American Mathematical Society, New York, 1927 (MR 98j:53001).

I.e., the study of general connections.

- {4} *Continuous Groups of Transformations*, Princeton University Press, Princeton, N.J., 1933.

- {5} *Transformations of Surfaces*, 2nd ed., Chelsea, New York, 1962.

A complement to Eisenhart {2}, going into greater detail on various classical transformations of surfaces. It doesn't look very interesting, but parts may turn out to be important, as they involve contact transformations (topic II.(f)).

- {6} *An Introduction to Differential Geometry, with use of the tensor calculus*, Princeton University Press, Princeton, N.J., 1940 (MR 2 154).

Ellis, G. F. R.

see Hawking, S. W.

Favard, J.

- {1} *Cours de Géométrie Différentielle Locale*, Gauthier-Villars, Paris, 1957 (MR 18 668).

A complete development of differential geometry, covering many topics in considerable detail, using É. Cartan's general method of moving frames (topic III.(g)), which is expounded at the beginning, before any geometry has been done. Shades of Bourbaki!

Fenchel, W.

Gromoll, D., Klingenberg, W., and Meyer, W.

- {1} *Riemannsche Geometrie im Grossen*, Springer-Verlag, Berlin, 1968 (MR 37 #4751).

These lecture notes, by three important differential geometers, give a modern presentation of intrinsic Riemannian geometry that starts right at the beginning and gets into recent deep global results. In addition, there are hundreds of examples and exercises that significantly extend the theory. By now many of the proofs have undoubtedly been simplified, and eventually the notes may become outdated, especially in light of Cheeger and Ebin {1}, but they are definitely worth owning. We cannot mention here all the topics covered, but the Sphere Theorem is certainly one of the most significant. There is a version of Klingenberg's Theorem (Theorem IV.8-36) for arbitrary dimensions (pg. 254), and attention might also be called to the Lemma on pg. 198—it gives an elementary version of the Morse theory proof of the Cartan-Hadamard Theorem (Theorem IV.8-13) in Milnor {2}.

Guggenheimer, H. W.

- {1} *Differential Geometry*, McGraw-Hill, New York, 1963 (MR 27 #6194).

The 1-parameter subgroups of the group of isometries of the hyperbolic plane are discussed in detail (pp. 276–278). The discussion of space curves in affine geometry (pp. 170–172) is especially interesting; it turns out that the analysis given in Chapter III.2 is not really adequate. Attention might also be called to exercise 12 on pg. 288.

Guillemin, V. and Pollack, A.

A beautiful extension, and complement, of Milnor {1}.

Haack, W.

- {1} *Elementare Differentialgeometrie*, Birkhäuser Verlag, Basel, 1955 (MR 18 596).

This seems to be the only book that treats infinitesimal bending by means of moving frames, and is the source for the material on pp. V.225–226. The author's definition seems to imply that the infinitesimal bend-

ing is non-trivial if and only if $\dot{\psi}_1^3$ or $\dot{\psi}_2^3$ is not identically zero, but I don't see offhand how to prove it. This fact is implicitly used in Problem V.12-4, which is a theorem of Weingarten (pg. 217); an analogous theorem (pg. 218) tells when "the lines of curvature remain lines of curvature in an infinitesimal bending" (i.e., when $\dot{l}_{12} = 0$). Eisenhart {2; 387} may be consulted for another proof, as well as for many examples of the "isothermal" surfaces arising in Problem V.12-4 (in particular, minimal surfaces are isothermal). For some modern theorems on infinitesimal bending that are basically translations of results about PDE's, see pp. 219–226. Finally, there is a proof (pp. 131–133) that only surfaces of constant curvature can be mapped conformally on the plane in such a way that the geodesics go to circles or straight lines. The proof is really unsatisfactory, for it uses certain lines that only exist on complex surfaces, and thus requires that the original surface be analytic. (I also know of no example to show that conformality of the mapping is a necessary hypothesis.) Bibliography of about 60 items.

Milnor, J. W.

- {1} *Topology from the Differentiable Viewpoint*, University Press of Virginia, Charlottesville, Virginia, 1965 (MR 37 #2239).

This book is not really about differential geometry at all, but about differential topology. But this is a field of related interest, and besides, anything written by Milnor is beautiful. See, in particular, §2 for the hard version of Sard's theorem.

- {2} *Morse Theory*, Princeton University Press, Princeton, N.J., 1963 (MR 31 #6249).

Although this book is really devoted to more advanced material from differential topology, a substantial part contains material from differential geometry. See, in particular, §6 and §19, where the Cartan-Hadamard theorem is proved using Morse theory (compare the remarks under Gromoll, Klingenberg, and Meyer {1}).

Milnor, J. W. and Stasheff, J. D.

- {1} *Characteristic Classes*, Princeton University Press, Princeton, N.J., 1974 (MR 55 #13428).

The first characteristic classes considered here are the Stiefel-Whitney classes, with \mathbb{Z}_2 coefficients. Since the actual construction of these classes, in §8, involves the Steenrod squares, it might be advisable simply to skip this section. §§9–15 proceed to define the Euler, Pontryagin, and Chern classes in the way mentioned in the “Valedictory” to Chapter V.13. The remaining §§ give applications beyond those interspersed in the preceding ones. We should explicitly mention that §11 identifies the Euler class of TM without invoking triangulations. §6 describes the cell structure for the Grassmannians by means of Schubert varieties. This cell structure was originally used by Ehresmann [1], [2] to compute the (integral) cohomology of the Grassmannians. From this one immediately obtains the real cohomology, which of course agrees with our calculations in Chapter V.13. Naturally it would be of interest to connect the two calculations directly, by determining the integrals over the Schubert varieties of the forms giving the Chern, Pontryagin, and Euler classes. I know of no reference to such calculations, except for the brief note of Chern [4] and the mimeographed notes of Chern {2}.

Osserman, R.

- {1} *Survey of Minimal Surfaces*, Van Nostrand Reinhold, New York, 1969 (MR 41 #934).

A good place to learn more about minimal surfaces, and minimal submanifolds, with a large bibliography. I would probably have gone out of my mind trying to write Chapter IV.9 if it hadn't been for this book, which clears up things that standard texts have contentedly left in a muddle for years. For example, nowhere else are the poles of g considered in the Enneper-Weierstrass representation of minimal surfaces. Also, almost all classical books consider all minimal surfaces to be complex surfaces. This is valid, since minimal surfaces are analytic, and can therefore be complexified, but it usually leads to results that have no real geometric significance. For example, a theorem of Lie (cf. Blaschke {1; v.1, pg. 236}, Haack {1; pg. 140}, or Kreyszig {1; pg. 244}) says that every minimal surface is a “translation surface”, of the form $(s, t) \mapsto f(s) + g(t)$. But this is only true if f and g are complex-valued; it is easy to see that the only minimal surfaces of this form for \mathbb{R}^3 -valued functions f and g is Scherk's minimal surface (in fact, that's how the surface was discovered).

{1} *Ricci-Calculus*, 2nd ed., Springer-Verlag, Berlin, 1954 (MR 16 521).

This book was written to show the great superiority of the classical notation. Reading it, one can see why differential geometry was once given up for dead. There are super-, sub-, pre- and post-scripts, including dots, brackets, etc. It is certainly a triumph of the printer's art, but is also supposed to be important for its considerations of non-symmetric connections (sometimes considered in general relativity). There is an enormous bibliography. Amusing footnotes on pp. 118, 160, 172.

See pg. 87 for a direct verification of the fact that all partial derivatives of g_{ij} at the center of a normal coordinate system are expressible in terms of the covariant derivatives of the curvature tensor (compare pp. IV.156–157). The original proof of this fact was by Vermeil [1]. By

the way, “normal coordinates” have been used for various tensors other than a Riemannian metric (cf. references at the end of Veblen {1; ch.6}, and also Weitzenböck {1; §§19–22}).

Another non-classical introduction to surface theory for undergraduates, this time in terms of principal bundles. The trick is that for surface theory the principal bundle degenerates to the sphere bundle and everything is much easier. Nevertheless, the book is not easy going. Chapter 6 contains a weird proof of the de Rham theorem.

Warner, F. W.

{1} *Foundations of Differentiable Manifolds and Lie Groups*, Scott, Foresman and Co., Glenview, Ill., 1971 (MR 45 #4312).

The first part of this book treats manifold theory and Lie groups concisely, but with all the necessary details. The relationship between the functors $\mathcal{T}^k(V)$ and $\Omega^k(V)$ and the algebraists' $\bigotimes^k V$ and $\Lambda^k V$ are spelled out in detail in Chapter 2. The last theorem of that chapter formally states a fact which we have frequently used (e.g., in the proof of

Theorem IV.7-20). The third chapter gives a little more detail on Lie groups. The adjoint representation is treated explicitly, as is the universal covering group of a Lie group. See also exercise 15 on pg. 134 for a proof that the exponential map of $GL(n, \mathbb{C})$ is onto and exercise 18 on pg. 135 for the classification of Abelian Lie groups.

The second and third parts of the book give connected presentations of material available nowhere else. The sheaf-theoretic proof of de Rham's theorem is given in the second part: Alexander-Spanier, Čech, and singular cohomologies are all mentioned, the isomorphism between de Rham and singular cohomology is shown to be given by integration, and the wedge product is shown to correspond to cup product.* (Although a simple proof of the de Rham theorem was outlined in Problem I.11-14, the sheaf-theoretic proof explains, in some sense, "why" the theorem is true, for it shows that only certain basic facts ($d^2 = 0$, the local converse, and existence of partitions of unity) matter, while the details of how they are obtained is irrelevant.) The third part of the book gives a completely self-contained elementary treatment of the Hodge theorem.

Wasserman, R.

{1} *Tensors and Manifolds*, The Clarendon Press, Oxford University Press, New York, 1992 (MR 93h:53002).

The reader might be concerned, as I was, whether this holds for our wedge product, with the factor $(p+q)!/p!q!$, or for the wedge product without this factor. The answer is that it holds for either! One way to see this is the following. In $\Lambda^k(V)$, regarded as a quotient vector space of $\bigotimes^k V$, there is a natural \wedge product ($v_1 \wedge \cdots \wedge v_k$ is the residue class of $v_1 \otimes \cdots \otimes v_k$), and this wedge product on each $\Lambda^k(M_p^)$ gives a wedge product on differential forms if we regard a k -form as a function $p \mapsto \omega(p) \in \Lambda^k(M_p^*)$. It is then this wedge product that corresponds to cup product under the de Rham isomorphism, so long as we define integration so that the integral of $f dx^1 \wedge \cdots \wedge dx^n$ on \mathbb{R}^n is just the ordinary integral of f . Now we can also get a wedge product on $\Omega^k(V)$ by means of an isomorphism of $\Omega^k(V)$ with $\Lambda^k(V^*)$. One isomorphism will give our wedge product, while another will give the product without the factor $(p+q)!/p!q!$, but in either case the wedge product will correspond to cup product. If this explanation seems too paradoxical, the following may help. For a k -form ω on M and a singular k -cube $c: [0, 1]^k \rightarrow M$, we define $\int_c \omega$ as the ordinary integral of f over $[0, 1]^k$ where

$$c^*\omega = f dx^1 \wedge \cdots \wedge dx^k.$$

In this definition, we naturally use the same \wedge in $dx^1 \wedge \cdots \wedge dx^k$ as we use in taking the product $\omega \wedge \eta$ on our manifold M ; if we change the definition of \wedge , then we also end up changing the definition of $\int_c \omega$, and the change involves just the right factor so that \wedge still corresponds to cup product.

Wolf, J. A.

{1} *Spaces of Constant Curvature*, 5th ed. Publish or Perish, Houston, Texas, 1984 (MR 88k:53002; 36 #829).

After a rapid run through Riemannian geometry, this book gets down to the main task of classifying complete manifolds of constant curvature. This is basically an algebraic problem, since all such manifolds have the standard simply-connected examples as their universal covering spaces. The case of n -dimensional manifolds M of constant positive curvature is easy for n even: M is S^n or \mathbb{P}^n (pg. 74 or Kobayashi and Nomizu {1; v.1, Note 4}). Other cases are not so easy, and all sorts of interesting material gets woven together in the search for the final classification.

Christoffel, E. B.

- [1] *Ueber die Transformation der homogenen Differentialausdrücke zweiten Grades*, J. Reine Angew. Math. **70** (1869), 46–70.

I could not resist mentioning this extraordinarily impressive paper, which appeared just one year after the publication of Riemann's inaugural lecture. Christoffel defines covariant differentiation, uses it to define the curvature tensor, and solves the problem of determining when two Riemannian manifolds are locally isometric. This is done essentially as in chapter V.7, Addendum 3, although the argument is not phrased in terms of the bundle of frames—the latter formulation comes from Cartan {3}.

- [1] *On nonlinear partial differential equations with two independent variables*, Comm. Pure Appl. Math. **2** (1949), 255–273 (MR 11 441).

Note that the region R_δ on pg. 263 is defined incorrectly—it has very steep sides, rather than the opposite. In the footnote on pg. 260 the authors make a more serious error; it amounts to asserting that the matrix A on pp. V.75–76 need not be assumed invertible, because this can always be achieved by an affine transformation of the plane. But, in fact, this works only if the dimension of $\ker A$ is only 1. Finally, the process by which the authors reach their equation (4.6) on pg. 261 is to me mysteriously complicated. For the arguments on pp. V.77–78, I used Lax's NYU notes on PDE's (1949–1950).

- [1] *On the curvatures of a curve in Riemann space*, Trans. Amer. Math. Soc. **33** (1931), 832–838.

This paper contains a generalization of Theorem IV.7-9: Let N be an arbitrary Riemannian manifold, let $M \subset N$ be a j -dimensional totally geodesic submanifold, and let $c: [a, b] \rightarrow N$ be an arclength parameterized curve with $\kappa_1, \dots, \kappa_{j-1}$ nowhere zero, and κ_j everywhere zero. Suppose that $c(a) \in M$ and $\mathbf{v}_i(a) \in M_{c(a)}$ for $i = 1, \dots, j$. Then $c([a, b]) \subset M$.

Flanders, H.

- [1] *Local theory of affine hypersurfaces*, J. Analyse Math. **15** (1965), 353–387 (MR 32 #403).

This paper uses moving frames to describe the (local) theory of hypersurfaces M^n of \mathbb{R}^{n+1} in special affine geometry. Global questions of special affine geometry for surfaces in \mathbb{R}^3 were first studied by Blaschke (see Blaschke {1; v.2}). Santalo [1] used moving frames, and derived integral formulas, for the same purpose, and Hsiung and Shahin [1] do the same thing for hypersurfaces in higher dimension. Section 10 of Flanders' paper gives a formula for the special affine second fundamental form \mathbf{II} —more precisely, it gives a formula for $\mathbf{II}(c', c', c')$ for a curve c

in M (compare Blaschke {1; v.2, §46} and Hsiung and Shahin [1, §4]). Section 2 indicates one crucial difference between the cases $n = 2$ and $n \geq 3$: in the latter case, the special affine Codazzi-Mainardi equations are a consequence of the apolarity conditions; this essentially depends on the Bianchi identities (compare Blaschke {1; v.2; §§65,66}). In ordinary geometry there is a similar situation for $n \geq 4$ (see Eisenhart {1; Appendix 22}).

Editors' Foreword

Mathematics has been expanding in all directions at a fabulous rate during the past half century. New fields have emerged, the diffusion into other disciplines has proceeded apace, and our knowledge of the classical areas has grown ever more profound. At the same time, one of the most striking trends in modern mathematics is the constantly increasing interrelationship between its various branches. Thus the present-day students of mathematics are faced with an immense mountain of material. In addition to the traditional areas of mathematics as presented in the traditional manner—and these presentations do abound—there are the new and often enlightening ways of looking at these traditional areas, and also the vast new areas teeming with potentialities. Much of this new material is scattered indigestibly throughout the research journals, and frequently coherently organized only in the minds or unpublished notes of the working mathematicians. And students desperately need to learn more and more of this material.

This series of brief topical booklets has been conceived as a possible means to tackle and hopefully to alleviate some of

these pedagogical problems. They are being written by active research mathematicians, who can look at the latest developments, who can use these developments to clarify and condense the required material, who know what ideas to underscore and what techniques to stress. We hope that they will also serve to present to the able undergraduate an introduction to contemporary research and problems in mathematics, and that they will be sufficiently informal that the personal tastes and attitudes of the leaders in modern mathematics will shine through clearly to the readers.

The area of differential geometry is one in which recent developments have effected great changes. That part of differential geometry centered about Stokes' Theorem, sometimes called the fundamental theorem of multivariate calculus, is traditionally taught in advanced calculus courses (second or third year) and is essential in engineering and physics as well as in several current and important branches of mathematics. However, the teaching of this material has been relatively little affected by these modern developments; so the mathematicians must relearn the material in graduate school, and other scientists are frequently altogether deprived of it. Dr. Spivak's book should be a help to those who wish to see Stokes' Theorem as the modern working mathematician sees it. A student with a good course in calculus and linear algebra behind him should find this book quite accessible.

Preface

This little book is especially concerned with those portions of “advanced calculus” in which the subtlety of the concepts and methods makes rigor difficult to attain at an elementary level. The approach taken here uses elementary versions of modern methods found in sophisticated mathematics. The formal prerequisites include only a term of linear algebra, a nodding acquaintance with the notation of set theory, and a respectable first-year calculus course (one which at least mentions the least upper bound (sup) and greatest lower bound (inf) of a set of real numbers). Beyond this a certain (perhaps latent) rapport with abstract mathematics will be found almost essential.

The first half of the book covers that simple part of advanced calculus which generalizes elementary calculus to higher dimensions. Chapter 1 contains preliminaries, and Chapters 2 and 3 treat differentiation and integration.

The remainder of the book is devoted to the study of curves, surfaces, and higher-dimensional analogues. Here the modern and classical treatments pursue quite different routes; there are, of course, many points of contact, and a significant encounter

occurs in the last section. The very classical equation reproduced on the cover appears also as the last theorem of the book. This theorem (Stokes' Theorem) has had a curious history and has undergone a striking metamorphosis.

The first statement of the Theorem appears as a postscript to a letter, dated July 2, 1850, from Sir William Thomson (Lord Kelvin) to Stokes. It appeared publicly as question 8 on the Smith's Prize Examination for 1854. This competitive examination, which was taken annually by the best mathematics students at Cambridge University, was set from 1849 to 1882 by Professor Stokes; by the time of his death the result was known universally as Stokes' Theorem. At least three proofs were given by his contemporaries: Thomson published one, another appeared in Thomson and Tait's *Treatise on Natural Philosophy*, and Maxwell provided another in *Electricity and Magnetism* [13]. Since this time the name of Stokes has been applied to much more general results, which have figured so prominently in the development of certain parts of mathematics that Stokes' Theorem may be considered a case study in the value of generalization.

In this book there are three forms of Stokes' Theorem. The version known to Stokes appears in the last section, along with its inseparable companions, Green's Theorem and the Divergence Theorem. These three theorems, the classical theorems of the subtitle, are derived quite easily from a modern Stokes' Theorem which appears earlier in Chapter 5. What the classical theorems state for curves and surfaces, this theorem states for the higher-dimensional analogues (manifolds) which are studied thoroughly in the first part of Chapter 5. This study of manifolds, which could be justified solely on the basis of their importance in modern mathematics, actually involves no more effort than a careful study of curves and surfaces alone would require.

The reader probably suspects that the modern Stokes' Theorem is at least as difficult as the classical theorems derived from it. On the contrary, it is a very simple consequence of yet another version of Stokes' Theorem; this very abstract version is the final and main result of Chapter 4.

It is entirely reasonable to suppose that the difficulties so far avoided must be hidden here. Yet the proof of this theorem is, in the mathematician's sense, an utter triviality—a straightforward computation. On the other hand, even the statement of this triviality cannot be understood without a horde of difficult definitions from Chapter 4. There are good reasons why the theorems should all be easy and the definitions hard. As the evolution of Stokes' Theorem revealed, a single simple principle can masquerade as several difficult results; the proofs of many theorems involve merely stripping away the disguise. The definitions, on the other hand, serve a twofold purpose: they are rigorous replacements for vague notions, and machinery for elegant proofs. The first two sections of Chapter 4 define precisely, and prove the rules for manipulating, what are classically described as "expressions of the form" $P dx + Q dy + R dz$, or $P dx dy + Q dy dz + R dz dx$. Chains, defined in the third section, and partitions of unity (already introduced in Chapter 3) free our proofs from the necessity of chopping manifolds up into small pieces; they reduce questions about manifolds, where everything seems hard, to questions about Euclidean space, where everything is easy.

Concentrating the depth of a subject in the definitions is undeniably economical, but it is bound to produce some difficulties for the student. I hope the reader will be encouraged to learn Chapter 4 thoroughly by the assurance that the results will justify the effort: the classical theorems of the last section represent only a few, and by no means the most important, applications of Chapter 4; many others appear as problems, and further developments will be found by exploring the bibliography.

The problems and the bibliography both deserve a few words. Problems appear after every section and are numbered (like the theorems) within chapters. I have starred those problems whose results are used in the text, but this precaution should be unnecessary—the problems are the most important part of the book, and the reader should at least attempt them all. It was necessary to make the bibliography either very incomplete or unwieldy, since half the major

branches of mathematics could legitimately be recommended as reasonable continuations of the material in the book. I have tried to make it incomplete but tempting.

Many criticisms and suggestions were offered during the writing of this book. I am particularly grateful to Richard Palais, Hugo Rossi, Robert Seeley, and Charles Stenard for their many helpful comments.

I have used this printing as an opportunity to correct many misprints and minor errors pointed out to me by indulgent readers. In addition, the material following Theorem 3-11 has been completely revised and corrected. Other important changes, which could not be incorporated in the text without excessive alteration, are listed in the Addenda at the end of the book.

Functions on Euclidean Space

NORM AND INNER PRODUCT

Euclidean n -space \mathbf{R}^n is defined as the set of all n -tuples (x^1, \dots, x^n) of real numbers x^i (a “1-tuple of numbers” is just a number and $\mathbf{R}^1 = \mathbf{R}$, the set of all real numbers). An element of \mathbf{R}^n is often called a point in \mathbf{R}^n , and \mathbf{R}^1 , \mathbf{R}^2 , \mathbf{R}^3 are often called the line, the plane, and space, respectively. If x denotes an element of \mathbf{R}^n , then x is an n -tuple of numbers, the i th one of which is denoted x^i ; thus we can write

$$x = (x^1, \dots, x^n).$$

A point in \mathbf{R}^n is frequently also called a vector in \mathbf{R}^n , because \mathbf{R}^n , with $x + y = (x^1 + y^1, \dots, x^n + y^n)$ and $ax = (ax^1, \dots, ax^n)$, as operations, is a vector space (over the real numbers, of dimension n). In this vector space there is the notion of the length of a vector x , usually called the **norm** $|x|$ of x and defined by $|x| = \sqrt{(x^1)^2 + \dots + (x^n)^2}$. If $n = 1$, then $|x|$ is the usual absolute value of x . The relation between the norm and the vector space structure of \mathbf{R}^n is very important.

1-1 Theorem. If $x, y \in \mathbf{R}^n$ and $a \in \mathbf{R}$, then

- (1) $|x| \geq 0$, and $|x| = 0$ if and only if $x = 0$.
- (2) $|\sum_{i=1}^n x^i y^i| \leq |x| \cdot |y|$; equality holds if and only if x and y are linearly dependent.
- (3) $|x + y| \leq |x| + |y|$.
- (4) $|ax| = |a| \cdot |x|$.

Proof

- (1) is left to the reader.
- (2) If x and y are linearly dependent, equality clearly holds.
If not, then $\lambda y - x \neq 0$ for all $\lambda \in \mathbf{R}$, so

$$\begin{aligned} 0 < |\lambda y - x|^2 &= \sum_{i=1}^n (\lambda y^i - x^i)^2 \\ &= \lambda^2 \sum_{i=1}^n (y^i)^2 - 2\lambda \sum_{i=1}^n x^i y^i + \sum_{i=1}^n (x^i)^2. \end{aligned}$$

Therefore the right side is a quadratic equation in λ with no real solution, and its discriminant must be negative. Thus

$$4 \left(\sum_{i=1}^n x^i y^i \right)^2 - 4 \sum_{i=1}^n (x^i)^2 \cdot \sum_{i=1}^n (y^i)^2 < 0.$$

- (3) $|x + y|^2 = \sum_{i=1}^n (x^i + y^i)^2$
 $= \sum_{i=1}^n (x^i)^2 + \sum_{i=1}^n (y^i)^2 + 2 \sum_{i=1}^n x^i y^i$
 $\leq |x|^2 + |y|^2 + 2|x| \cdot |y| \quad \text{by (2)}$
 $= (|x| + |y|)^2.$
- (4) $|ax| = \sqrt{\sum_{i=1}^n (ax^i)^2} = \sqrt{a^2 \sum_{i=1}^n (x^i)^2} = |a| \cdot |x|. \quad \blacksquare$

The quantity $\sum_{i=1}^n x^i y^i$ which appears in (2) is called the **inner product** of x and y and denoted $\langle x, y \rangle$. The most important properties of the inner product are the following.

1-2 Theorem. If x, x_1, x_2 and y, y_1, y_2 are vectors in \mathbf{R}^n and $a \in \mathbf{R}$, then

- (1) $\langle x, y \rangle = \langle y, x \rangle$ (symmetry).

- (2) $\langle ax, y \rangle = \langle x, ay \rangle = a\langle x, y \rangle$ (bilinearity).
 $\langle x_1 + x_2, y \rangle = \langle x_1, y \rangle + \langle x_2, y \rangle$
 $\langle x, y_1 + y_2 \rangle = \langle x, y_1 \rangle + \langle x, y_2 \rangle$
- (3) $\langle x, x \rangle \geq 0$, and $\langle x, x \rangle = 0$ if and only if $x = 0$ (positive definiteness).
- (4) $|x| = \sqrt{\langle x, x \rangle}$.
- (5) $\langle x, y \rangle = \frac{|x + y|^2 - |x - y|^2}{4}$ (polarization identity).

Proof

- (1) $\langle x, y \rangle = \sum_{i=1}^n x^i y^i = \sum_{i=1}^n y^i x^i = \langle y, x \rangle$.
 (2) By (1) it suffices to prove

$$\begin{aligned}\langle ax, y \rangle &= a\langle x, y \rangle, \\ \langle x_1 + x_2, y \rangle &= \langle x_1, y \rangle + \langle x_2, y \rangle.\end{aligned}$$

These follow from the equations

$$\begin{aligned}\langle ax, y \rangle &= \sum_{i=1}^n (ax^i) y^i = a \sum_{i=1}^n x^i y^i = a\langle x, y \rangle, \\ \langle x_1 + x_2, y \rangle &= \sum_{i=1}^n (x_1^i + x_2^i) y^i = \sum_{i=1}^n x_1^i y^i + \sum_{i=1}^n x_2^i y^i \\ &= \langle x_1, y \rangle + \langle x_2, y \rangle.\end{aligned}$$

(3) and (4) are left to the reader.

$$\begin{aligned}(5) \quad & \frac{|x + y|^2 - |x - y|^2}{4} \\ &= \frac{1}{4}[\langle x + y, x + y \rangle - \langle x - y, x - y \rangle] \quad \text{by (4)} \\ &= \frac{1}{4}[\langle x, x \rangle + 2\langle x, y \rangle + \langle y, y \rangle - (\langle x, x \rangle - 2\langle x, y \rangle + \langle y, y \rangle)] \\ &= \langle x, y \rangle. \quad \blacksquare\end{aligned}$$

We conclude this section with some important remarks about notation. The vector $(0, \dots, 0)$ will usually be denoted simply 0 . The **usual basis** of \mathbf{R}^n is e_1, \dots, e_n , where $e_i = (0, \dots, 1, \dots, 0)$, with the 1 in the i th place. If $T: \mathbf{R}^n \rightarrow \mathbf{R}^m$ is a linear transformation, the matrix of T with respect to the usual bases of \mathbf{R}^n and \mathbf{R}^m is the $m \times n$ matrix $A = (a_{ij})$, where $T(e_i) = \sum_{j=1}^m a_{ji} e_j$ —the coefficients of $T(e_i)$

appear in the i th *column* of the matrix. If $S: \mathbf{R}^m \rightarrow \mathbf{R}^p$ has the $p \times m$ matrix B , then $S \circ T$ has the $p \times n$ matrix BA [here $S \circ T(x) = S(T(x))$; most books on linear algebra denote $S \circ T$ simply ST]. To find $T(x)$ one computes the $m \times 1$ matrix

$$\begin{pmatrix} y^1 \\ \vdots \\ y^m \end{pmatrix} = \begin{pmatrix} a_{11} & \cdots & a_{1n} \\ \vdots & & \vdots \\ a_{m1} & \cdots & a_{mn} \end{pmatrix} \cdot \begin{pmatrix} x^1 \\ \vdots \\ x^n \end{pmatrix};$$

then $T(x) = (y^1, \dots, y^m)$. One notational convention greatly simplifies many formulas: if $x \in \mathbf{R}^n$ and $y \in \mathbf{R}^m$, then (x, y) denotes

$$(x^1, \dots, x^n, y^1, \dots, y^m) \in \mathbf{R}^{n+m}.$$

Problems. 1-1.* Prove that $|x| \leq \sum_{i=1}^n |x^i|$.

1-2. When does equality hold in Theorem 1-1(3)? *Hint:* Re-examine the proof; the answer is not “when x and y are linearly dependent.”

1-3. Prove that $|x - y| \leq |x| + |y|$. When does equality hold?

1-4. Prove that $||x| - |y|| \leq |x - y|$.

1-5. The quantity $|y - x|$ is called the **distance** between x and y . Prove and interpret geometrically the “triangle inequality”: $|z - x| \leq |z - y| + |y - x|$.

1-6. Let f and g be integrable on $[a, b]$.

(a) Prove that $|\int_a^b f \cdot g| \leq (\int_a^b f^2)^{\frac{1}{2}} \cdot (\int_a^b g^2)^{\frac{1}{2}}$. *Hint:* Consider separately the cases $0 = \int_a^b (f - \lambda g)^2$ for some $\lambda \in \mathbf{R}$ and $0 < \int_a^b (f - \lambda g)^2$ for all $\lambda \in \mathbf{R}$.

(b) If equality holds, must $f = \lambda g$ for some $\lambda \in \mathbf{R}$? What if f and g are continuous?

(c) Show that Theorem 1-1(2) is a special case of (a).

1-7. A linear transformation $T: \mathbf{R}^n \rightarrow \mathbf{R}^n$ is **norm preserving** if $|T(x)| = |x|$, and **inner product preserving** if $\langle Tx, Ty \rangle = \langle x, y \rangle$.

(a) Prove that T is norm preserving if and only if T is inner-product preserving.

(b) Prove that such a linear transformation T is 1-1 and T^{-1} is of the same sort.

1-8. If $x, y \in \mathbf{R}^n$ are non-zero, the **angle** between x and y , denoted $\angle(x, y)$, is defined as $\arccos(\langle x, y \rangle / (|x| \cdot |y|))$, which makes sense by Theorem 1-1(2). The linear transformation T is **angle preserving** if T is 1-1, and for $x, y \neq 0$ we have $\angle(Tx, Ty) = \angle(x, y)$.

(a) Prove that if T is norm preserving, then T is angle preserving.

(b) If there is a basis x_1, \dots, x_n of \mathbf{R}^n and numbers $\lambda_1, \dots, \lambda_n$ such that $Tx_i = \lambda_i x_i$, prove that T is angle preserving if and only if all $|\lambda_i|$ are equal.

(c) What are all angle preserving $T: \mathbf{R}^n \rightarrow \mathbf{R}^n$?

1-9. If $0 \leq \theta < \pi$, let $T: \mathbf{R}^2 \rightarrow \mathbf{R}^2$ have the matrix $\begin{pmatrix} \cos \theta & \sin \theta \\ -\sin \theta & \cos \theta \end{pmatrix}$.

Show that T is angle preserving and if $x \neq 0$, then $\angle(x, Tx) = \theta$.

1-10.* If $T: \mathbf{R}^m \rightarrow \mathbf{R}^n$ is a linear transformation, show that there is a number M such that $|T(h)| \leq M|h|$ for $h \in \mathbf{R}^m$. *Hint:* Estimate $|T(h)|$ in terms of $|h|$ and the entries in the matrix of T .

1-11. If $x, y \in \mathbf{R}^n$ and $z, w \in \mathbf{R}^m$, show that $\langle (x, z), (y, w) \rangle = \langle x, y \rangle + \langle z, w \rangle$ and $|(x, z)| = \sqrt{|x|^2 + |z|^2}$. Note that (x, z) and (y, w) denote points in \mathbf{R}^{n+m} .

1-12.* Let $(\mathbf{R}^n)^*$ denote the dual space of the vector space \mathbf{R}^n . If $x \in \mathbf{R}^n$, define $\varphi_x \in (\mathbf{R}^n)^*$ by $\varphi_x(y) = \langle x, y \rangle$. Define $T: \mathbf{R}^n \rightarrow (\mathbf{R}^n)^*$ by $T(x) = \varphi_x$. Show that T is a 1-1 linear transformation and conclude that every $\varphi \in (\mathbf{R}^n)^*$ is φ_x for a unique $x \in \mathbf{R}^n$.

1-13.* If $x, y \in \mathbf{R}^n$, then x and y are called **perpendicular** (or **orthogonal**) if $\langle x, y \rangle = 0$. If x and y are perpendicular, prove that $|x + y|^2 = |x|^2 + |y|^2$.

SUBSETS OF EUCLIDEAN SPACE

The closed interval $[a, b]$ has a natural analogue in \mathbf{R}^2 . This is the **closed rectangle** $[a, b] \times [c, d]$, defined as the collection of all pairs (x, y) with $x \in [a, b]$ and $y \in [c, d]$. More generally, if $A \subset \mathbf{R}^m$ and $B \subset \mathbf{R}^n$, then $A \times B \subset \mathbf{R}^{m+n}$ is defined as the set of all $(x, y) \in \mathbf{R}^{m+n}$ with $x \in A$ and $y \in B$. In particular, $\mathbf{R}^{m+n} = \mathbf{R}^m \times \mathbf{R}^n$. If $A \subset \mathbf{R}^m$, $B \subset \mathbf{R}^n$, and $C \subset \mathbf{R}^p$, then $(A \times B) \times C = A \times (B \times C)$, and both of these are denoted simply $A \times B \times C$; this convention is extended to the product of any number of sets. The set $[a_1, b_1] \times \dots \times [a_n, b_n] \subset \mathbf{R}^n$ is called a **closed rectangle** in \mathbf{R}^n , while the set $(a_1, b_1) \times \dots \times (a_n, b_n) \subset \mathbf{R}^n$ is called an **open rectangle**. More generally a set $U \subset \mathbf{R}^n$ is called **open** (Figure 1-1) if for each $x \in U$ there is an open rectangle A such that $x \in A \subset U$.

A subset C of \mathbf{R}^n is **closed** if $\mathbf{R}^n - C$ is open. For example, if C contains only finitely many points, then C is closed.

**FIGURE 1-1**

The reader should supply the proof that a closed rectangle in \mathbf{R}^n is indeed a closed set.

If $A \subset \mathbf{R}^n$ and $x \in \mathbf{R}^n$, then one of three possibilities must hold (Figure 1-2):

1. There is an open rectangle B such that $x \in B \subset A$.
2. There is an open rectangle B such that $x \in B \subset \mathbf{R}^n - A$.
3. If B is any open rectangle with $x \in B$, then B contains points of both A and $\mathbf{R}^n - A$.

**FIGURE 1-2**

Those points satisfying (1) constitute the **interior** of A , those satisfying (2) the **exterior** of A , and those satisfying (3) the **boundary** of A . Problems 1-16 to 1-18 show that these terms may sometimes have unexpected meanings.

It is not hard to see that the interior of any set A is open, and the same is true for the exterior of A , which is, in fact, the interior of $\mathbf{R}^n - A$. Thus (Problem 1-14) their union is open, and what remains, the boundary, must be closed.

A collection \mathcal{O} of open sets is an **open cover** of A (or, briefly, **covers** A) if every point $x \in A$ is in some open set in the collection \mathcal{O} . For example, if \mathcal{O} is the collection of all open intervals $(a, a + 1)$ for $a \in \mathbf{R}$, then \mathcal{O} is a cover of \mathbf{R} . Clearly no finite number of the open sets in \mathcal{O} will cover \mathbf{R} or, for that matter, any unbounded subset of \mathbf{R} . A similar situation can also occur for bounded sets. If \mathcal{O} is the collection of all open intervals $(1/n, 1 - 1/n)$ for all integers $n > 1$, then \mathcal{O} is an open cover of $(0,1)$, but again no finite collection of sets in \mathcal{O} will cover $(0,1)$. Although this phenomenon may not appear particularly scandalous, sets for which this state of affairs cannot occur are of such importance that they have received a special designation: a set A is called **compact** if every open cover \mathcal{O} contains a finite subcollection of open sets which also covers A .

A set with only finitely many points is obviously compact and so is the infinite set A which contains 0 and the numbers $1/n$ for all integers n (reason: if \mathcal{O} is a cover, then $0 \in U$ for some open set U in \mathcal{O} ; there are only finitely many other points of A not in U , each requiring at most one more open set).

Recognizing compact sets is greatly simplified by the following results, of which only the first has any depth (i.e., uses any facts about the real numbers).

1-3 Theorem (Heine-Borel). *The closed interval $[a,b]$ is compact.*

Proof. If \mathcal{O} is an open cover of $[a,b]$, let

$A = \{x: a \leq x \leq b \text{ and } [a,x] \text{ is covered by some finite number of open sets in } \mathcal{O}\}.$

FIGURE 1-3

Note that $a \in A$ and that A is clearly bounded above (by b). We would like to show that $b \in A$. This is done by proving two things about $\alpha = \text{least upper bound of } A$; namely, (1) $\alpha \in A$ and (2) $b = \alpha$.

Since \mathcal{O} is a cover, $\alpha \in U$ for some U in \mathcal{O} . Then all points in some interval to the left of α are also in U (see Figure 1-3). Since α is the least upper bound of A , there is an x in this interval such that $x \in A$. Thus $[a, x]$ is covered by some finite number of open sets of \mathcal{O} , while $[x, \alpha]$ is covered by the single set U . Hence $[a, \alpha]$ is covered by a finite number of open sets of \mathcal{O} , and $\alpha \in A$. This proves (1).

To prove that (2) is true, suppose instead that $\alpha < b$. Then there is a point x' between α and b such that $[\alpha, x'] \subset U$. Since $\alpha \in A$, the interval $[a, \alpha]$ is covered by finitely many open sets of \mathcal{O} , while $[\alpha, x']$ is covered by U . Hence $x' \in A$, contradicting the fact that α is an upper bound of A . ■

If $B \subset \mathbf{R}^m$ is compact and $x \in \mathbf{R}^n$, it is easy to see that $\{x\} \times B \subset \mathbf{R}^{n+m}$ is compact. However, a much stronger assertion can be made.

1-4 Theorem. *If B is compact and \mathcal{O} is an open cover of $\{x\} \times B$, then there is an open set $U \subset \mathbf{R}^n$ containing x such that $U \times B$ is covered by a finite number of sets in \mathcal{O} .*

Proof. Since $\{x\} \times B$ is compact, we can assume at the outset that \mathcal{O} is finite, and we need only find the open set U such that $U \times B$ is covered by \mathcal{O} .

For each $y \in B$ the point (x, y) is in some open set W in \mathcal{O} . Since W is open, we have $(x, y) \in U_y \times V_y \subset W$ for some open rectangle $U_y \times V_y$. The sets V_y cover the compact set B , so a finite number V_{y_1}, \dots, V_{y_k} also cover B . Let $U = U_{y_1} \cap \dots \cap U_{y_k}$. Then if $(x', y') \in U \times B$, we have

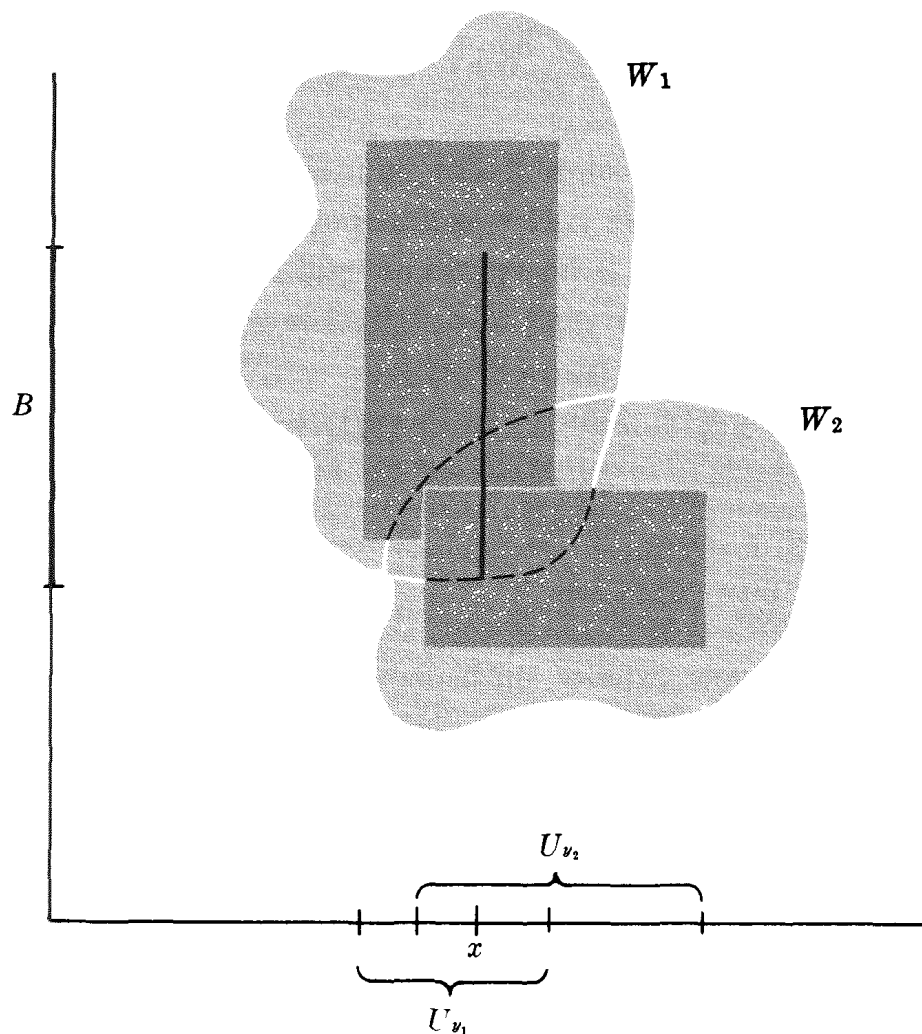

FIGURE 1-4

$y' \in V_{y_i}$ for some i (Figure 1-4), and certainly $x' \in U_{y_i}$. Hence $(x', y') \in U_{y_i} \times V_{y_i}$, which is contained in some W in \mathcal{O} . ■

1-5 Corollary. If $A \subset \mathbf{R}^n$ and $B \subset \mathbf{R}^m$ are compact, then $A \times B \subset \mathbf{R}^{n+m}$ is compact.

Proof. If \mathcal{O} is an open cover of $A \times B$, then \mathcal{O} covers $\{x\} \times B$ for each $x \in A$. By Theorem 1-4 there is an open set U_x containing x such that $U_x \times B$ is covered by finitely many sets in \mathcal{O} . Since A is compact, a finite number U_{x_1}, \dots, U_{x_n} of the U_x cover A . Since finitely many sets in \mathcal{O} cover each $U_{x_i} \times B$, finitely many cover all of $A \times B$. ■

1-6 Corollary. $A_1 \times \dots \times A_k$ is compact if each A_i is. In particular, a closed rectangle in \mathbf{R}^k is compact.

1-7 Corollary. *A closed bounded subset of \mathbf{R}^n is compact.*
(The converse is also true (Problem 1-20).)

Proof. If $A \subset \mathbf{R}^n$ is closed and bounded, then $A \subset B$ for some closed rectangle B . If \mathcal{O} is an open cover of A , then \mathcal{O} together with $\mathbf{R}^n - A$ is an open cover of B . Hence a finite number U_1, \dots, U_n of sets in \mathcal{O} , together with $\mathbf{R}^n - A$ perhaps, cover B . Then U_1, \dots, U_n cover A . ■

Problems. 1-14.* Prove that the union of any (even infinite) number of open sets is open. Prove that the intersection of two (and hence of finitely many) open sets is open. Give a counterexample for infinitely many open sets.

1-15. Prove that $\{x \in \mathbf{R}^n: |x - a| < r\}$ is open (see also Problem 1-27).

1-16. Find the interior, exterior, and boundary of the sets

$$\begin{aligned} &\{x \in \mathbf{R}^n: |x| \leq 1\} \\ &\{x \in \mathbf{R}^n: |x| = 1\} \\ &\{x \in \mathbf{R}^n: \text{each } x^i \text{ is rational}\}. \end{aligned}$$

1-17. Construct a set $A \subset [0,1] \times [0,1]$ such that A contains at most one point on each horizontal and each vertical line but boundary $A = [0,1] \times [0,1]$. *Hint:* It suffices to ensure that A contains points in each quarter of the square $[0,1] \times [0,1]$ and also in each sixteenth, etc.

1-18. If $A \subset [0,1]$ is the union of open intervals (a_i, b_i) such that each rational number in $(0,1)$ is contained in some (a_i, b_i) , show that boundary $A = [0,1] - A$.

1-19.* If A is a closed set that contains every rational number $r \in [0,1]$, show that $[0,1] \subset A$.

1-20. Prove the converse of Corollary 1-7: A compact subset of \mathbf{R}^n is closed and bounded (see also Problem 1-28).

1-21.* (a) If A is closed and $x \notin A$, prove that there is a number $d > 0$ such that $|y - x| \geq d$ for all $y \in A$.

(b) If A is closed, B is compact, and $A \cap B = \emptyset$, prove that there is $d > 0$ such that $|y - x| \geq d$ for all $y \in A$ and $x \in B$. *Hint:* For each $b \in B$ find an open set U containing b such that this relation holds for $x \in U \cap B$.

(c) Give a counterexample in \mathbf{R}^2 if A and B are closed but neither is compact.

1-22.* If U is open and $C \subset U$ is compact, show that there is a compact set D such that $C \subset \text{interior } D$ and $D \subset U$.

FUNCTIONS AND CONTINUITY

A **function** from \mathbf{R}^n to \mathbf{R}^m (sometimes called a (vector-valued) function of n variables) is a rule which associates to each point in \mathbf{R}^n some point in \mathbf{R}^m ; the point a function f associates to x is denoted $f(x)$. We write $f: \mathbf{R}^n \rightarrow \mathbf{R}^m$ (read “ f takes \mathbf{R}^n into \mathbf{R}^m ” or “ f , taking \mathbf{R}^n into \mathbf{R}^m ,” depending on context) to indicate that $f(x) \in \mathbf{R}^m$ is defined for $x \in \mathbf{R}^n$. The notation $f: A \rightarrow \mathbf{R}^m$ indicates that $f(x)$ is defined only for x in the set A , which is called the **domain** of f . If $B \subset A$, we define $f(B)$ as the set of all $f(x)$ for $x \in B$, and if $C \subset \mathbf{R}^m$ we define $f^{-1}(C) = \{x \in A: f(x) \in C\}$. The notation $f: A \rightarrow B$ indicates that $f(A) \subset B$.

A convenient representation of a function $f: \mathbf{R}^2 \rightarrow \mathbf{R}$ may be obtained by drawing a picture of its graph, the set of all 3-tuples of the form $(x, y, f(x, y))$, which is actually a figure in 3-space (see, e.g., Figures 2-1 and 2-2 of Chapter 2).

If $f, g: \mathbf{R}^n \rightarrow \mathbf{R}$, the functions $f + g$, $f - g$, $f \cdot g$, and f/g are defined precisely as in the one-variable case. If $f: A \rightarrow \mathbf{R}^m$ and $g: B \rightarrow \mathbf{R}^p$, where $B \subset \mathbf{R}^m$, then the **composition** $g \circ f$ is defined by $g \circ f(x) = g(f(x))$; the domain of $g \circ f$ is $A \cap f^{-1}(B)$. If $f: A \rightarrow \mathbf{R}^m$ is 1-1, that is, if $f(x) \neq f(y)$ when $x \neq y$, we define $f^{-1}: f(A) \rightarrow \mathbf{R}^n$ by the requirement that $f^{-1}(z)$ is the unique $x \in A$ with $f(x) = z$.

A function $f: A \rightarrow \mathbf{R}^m$ determines m **component functions** $f^1, \dots, f^m: A \rightarrow \mathbf{R}$ by $f(x) = (f^1(x), \dots, f^m(x))$. If conversely, m functions $g_1, \dots, g_m: A \rightarrow \mathbf{R}$ are given, there is a unique function $f: A \rightarrow \mathbf{R}^m$ such that $f^i = g_i$, namely $f(x) = (g_1(x), \dots, g_m(x))$. This function f will be denoted (g_1, \dots, g_m) , so that we always have $f = (f^1, \dots, f^m)$. If $\pi: \mathbf{R}^n \rightarrow \mathbf{R}^n$ is the identity function, $\pi(x) = x$, then $\pi^i(x) = x^i$; the function π^i is called the i th **projection function**.

The notation $\lim_{x \rightarrow a} f(x) = b$ means, as in the one-variable case, that we can get $f(x)$ as close to b as desired, by choosing x sufficiently close to, but not equal to, a . In mathematical terms this means that for every number $\epsilon > 0$ there is a number $\delta > 0$ such that $|f(x) - b| < \epsilon$ for all x in the domain of f which

satisfy $0 < |x - a| < \delta$. A function $f: A \rightarrow \mathbf{R}^m$ is called **continuous** at $a \in A$ if $\lim_{x \rightarrow a} f(x) = f(a)$, and f is simply called con-

tinuous if it is continuous at each $a \in A$. One of the pleasant surprises about the concept of continuity is that it can be defined without using limits. It follows from the next theorem that $f: \mathbf{R}^n \rightarrow \mathbf{R}^m$ is continuous if and only if $f^{-1}(U)$ is open whenever $U \subset \mathbf{R}^m$ is open; if the domain of f is not all of \mathbf{R}^n , a slightly more complicated condition is needed.

1-8 Theorem. *If $A \subset \mathbf{R}^n$, a function $f: A \rightarrow \mathbf{R}^m$ is continuous if and only if for every open set $U \subset \mathbf{R}^m$ there is some open set $V \subset \mathbf{R}^n$ such that $f^{-1}(U) = V \cap A$.*

Proof. Suppose f is continuous. If $a \in f^{-1}(U)$, then $f(a) \in U$. Since U is open, there is an open rectangle B with $f(a) \in B \subset U$. Since f is continuous at a , we can ensure that $f(x) \in B$, provided we choose x in some sufficiently small rectangle C containing a . Do this for each $a \in f^{-1}(U)$ and let V be the union of all such C . Clearly $f^{-1}(U) = V \cap A$. The converse is similar and is left to the reader. ■

The following consequence of Theorem 1-8 is of great importance.

1-9 Theorem. *If $f: A \rightarrow \mathbf{R}^m$ is continuous, where $A \subset \mathbf{R}^n$, and A is compact, then $f(A) \subset \mathbf{R}^m$ is compact.*

Proof. Let \mathcal{O} be an open cover of $f(A)$. For each open set U in \mathcal{O} there is an open set V_U such that $f^{-1}(U) = V_U \cap A$. The collection of all V_U is an open cover of A . Since A is compact, a finite number V_{U_1}, \dots, V_{U_n} cover A . Then U_1, \dots, U_n cover $f(A)$. ■

If $f: A \rightarrow \mathbf{R}$ is bounded, the extent to which f fails to be continuous at $a \in A$ can be measured in a precise way. For $\delta > 0$ let

$$M(a, f, \delta) = \sup\{f(x) : x \in A \text{ and } |x - a| < \delta\},$$

$$m(a, f, \delta) = \inf\{f(x) : x \in A \text{ and } |x - a| < \delta\}.$$

The **oscillation** $o(f,a)$ of f at a is defined by $o(f,a) = \lim_{\delta \rightarrow 0} [M(a,f,\delta) - m(a,f,\delta)]$. This limit always exists, since $M(a,f,\delta) - m(a,f,\delta)$ decreases as δ decreases. There are two important facts about $o(f,a)$.

1-10 Theorem. *The bounded function f is continuous at a if and only if $o(f,a) = 0$.*

Proof. Let f be continuous at a . For every number $\varepsilon > 0$ we can choose a number $\delta > 0$ so that $|f(x) - f(a)| < \varepsilon$ for all $x \in A$ with $|x - a| < \delta$; thus $M(a,f,\delta) - m(a,f,\delta) \leq 2\varepsilon$. Since this is true for every ε , we have $o(f,a) = 0$. The converse is similar and is left to the reader. ■

1-11 Theorem. *Let $A \subset \mathbf{R}^n$ be closed. If $f: A \rightarrow \mathbf{R}$ is any bounded function, and $\varepsilon > 0$, then $\{x \in A: o(f,x) \geq \varepsilon\}$ is closed.*

Proof. Let $B = \{x \in A: o(f,x) \geq \varepsilon\}$. We wish to show that $\mathbf{R}^n - B$ is open. If $x \in \mathbf{R}^n - B$, then either $x \notin A$ or else $x \in A$ and $o(f,x) < \varepsilon$. In the first case, since A is closed, there is an open rectangle C containing x such that $C \subset \mathbf{R}^n - A \subset \mathbf{R}^n - B$. In the second case there is a $\delta > 0$ such that $M(x,f,\delta) - m(x,f,\delta) < \varepsilon$. Let C be an open rectangle containing x such that $|x - y| < \delta$ for all $y \in C$. Then if $y \in C$ there is a δ_1 such that $|x - z| < \delta$ for all z satisfying $|z - y| < \delta_1$. Thus $M(y,f,\delta_1) - m(y,f,\delta_1) < \varepsilon$, and consequently $o(y,f) < \varepsilon$. Therefore $C \subset \mathbf{R}^n - B$. ■

Problems. 1-23. If $f: A \rightarrow \mathbf{R}^m$ and $a \in A$, show that $\lim_{x \rightarrow a} f(x) = b$ if and only if $\lim_{x \rightarrow a} f^i(x) = b^i$ for $i = 1, \dots, m$.

1-24. Prove that $f: A \rightarrow \mathbf{R}^m$ is continuous at a if and only if each f^i is.

1-25. Prove that a linear transformation $T: \mathbf{R}^n \rightarrow \mathbf{R}^m$ is continuous.

Hint: Use Problem 1-10.

1-26. Let $A = \{(x,y) \in \mathbf{R}^2: x > 0 \text{ and } 0 < y < x^2\}$.

(a) Show that every straight line through $(0,0)$ contains an interval around $(0,0)$ which is in $\mathbf{R}^2 - A$.

(b) Define $f: \mathbf{R}^2 \rightarrow \mathbf{R}$ by $f(x) = 0$ if $x \notin A$ and $f(x) = 1$ if $x \in A$. For $h \in \mathbf{R}^2$ define $g_h: \mathbf{R} \rightarrow \mathbf{R}$ by $g_h(t) = f(th)$. Show that each g_h is continuous at 0, but f is not continuous at $(0,0)$.

- 1-27. Prove that $\{x \in \mathbf{R}^n: |x - a| < r\}$ is open by considering the function $f: \mathbf{R}^n \rightarrow \mathbf{R}$ with $f(x) = |x - a|$.
- 1-28. If $A \subset \mathbf{R}^n$ is not closed, show that there is a continuous function $f: A \rightarrow \mathbf{R}$ which is unbounded. *Hint:* If $x \in \mathbf{R}^n - A$ but $x \notin \text{interior}(\mathbf{R}^n - A)$, let $f(y) = 1/|y - x|$.
- 1-29. If A is compact, prove that every continuous function $f: A \rightarrow \mathbf{R}$ takes on a maximum and a minimum value.
- 1-30. Let $f: [a, b] \rightarrow \mathbf{R}$ be an increasing function. If $x_1, \dots, x_n \in [a, b]$ are distinct, show that $\sum_{i=1}^n (f(x_i) - f(x_{i-1})) < f(b) - f(a)$.

Differentiation

BASIC DEFINITIONS

Recall that a function $f: \mathbf{R} \rightarrow \mathbf{R}$ is differentiable at $a \in \mathbf{R}$ if there is a number $f'(a)$ such that

$$(1) \lim_{h \rightarrow 0} \frac{f(a+h) - f(a)}{h} = f'(a).$$

This equation certainly makes no sense in the general case of a function $f: \mathbf{R}^n \rightarrow \mathbf{R}^m$, but can be reformulated in a way that does. If $\lambda: \mathbf{R} \rightarrow \mathbf{R}$ is the linear transformation defined by $\lambda(h) = f'(a) \cdot h$, then equation (1) is equivalent to

$$(2) \lim_{h \rightarrow 0} \frac{f(a+h) - f(a) - \lambda(h)}{h} = 0.$$

Equation (2) is often interpreted as saying that $\lambda + f(a)$ is a good approximation to f at a (see Problem 2-9). Henceforth we focus our attention on the linear transformation λ and reformulate the definition of differentiability as follows.

A function $f: \mathbf{R} \rightarrow \mathbf{R}$ is differentiable at $a \in \mathbf{R}$ if there is a linear transformation $\lambda: \mathbf{R} \rightarrow \mathbf{R}$ such that

$$\lim_{h \rightarrow 0} \frac{f(a+h) - f(a) - \lambda(h)}{h} = 0.$$

In this form the definition has a simple generalization to higher dimensions:

A function $f: \mathbf{R}^n \rightarrow \mathbf{R}^m$ is **differentiable** at $a \in \mathbf{R}^n$ if there is a linear transformation $\lambda: \mathbf{R}^n \rightarrow \mathbf{R}^m$ such that

$$\lim_{h \rightarrow 0} \frac{|f(a+h) - f(a) - \lambda(h)|}{|h|} = 0.$$

Note that h is a point of \mathbf{R}^n and $f(a+h) - f(a) - \lambda(h)$ a point of \mathbf{R}^m , so the norm signs are essential. The linear transformation λ is denoted $Df(a)$ and called the **derivative** of f at a . The justification for the phrase “the linear transformation λ ” is

2-1 Theorem. *If $f: \mathbf{R}^n \rightarrow \mathbf{R}^m$ is differentiable at $a \in \mathbf{R}^n$ there is a unique linear transformation $\lambda: \mathbf{R}^n \rightarrow \mathbf{R}^m$ such that*

$$\lim_{h \rightarrow 0} \frac{|f(a+h) - f(a) - \lambda(h)|}{|h|} = 0.$$

Proof. Suppose $\mu: \mathbf{R}^n \rightarrow \mathbf{R}^m$ satisfies

$$\lim_{h \rightarrow 0} \frac{|f(a+h) - f(a) - \mu(h)|}{|h|} = 0.$$

If $d(h) = f(a+h) - f(a)$, then

$$\begin{aligned} \lim_{h \rightarrow 0} \frac{|\lambda(h) - \mu(h)|}{|h|} &= \lim_{h \rightarrow 0} \frac{|\lambda(h) - d(h) + d(h) - \mu(h)|}{|h|} \\ &\leq \lim_{h \rightarrow 0} \frac{|\lambda(h) - d(h)|}{|h|} + \lim_{h \rightarrow 0} \frac{|d(h) - \mu(h)|}{|h|} \\ &= 0. \end{aligned}$$

If $x \in \mathbf{R}^n$, then $tx \rightarrow 0$ as $t \rightarrow 0$. Hence for $x \neq 0$ we have

$$0 = \lim_{t \rightarrow 0} \frac{|\lambda(tx) - \mu(tx)|}{|tx|} = \frac{|\lambda(x) - \mu(x)|}{|x|}.$$

Therefore $\lambda(x) = \mu(x)$. ■

We shall later discover a simple way of finding $Df(a)$. For the moment let us consider the function $f: \mathbf{R}^2 \rightarrow \mathbf{R}$ defined by $f(x, y) = \sin x$. Then $Df(a, b) = \lambda$ satisfies $\lambda(x, y) = (\cos a) \cdot x$. To prove this, note that

$$\begin{aligned} \lim_{(h,k) \rightarrow 0} \frac{|f(a+h, b+k) - f(a, b) - \lambda(h, k)|}{|(h, k)|} \\ = \lim_{(h,k) \rightarrow 0} \frac{|\sin(a+h) - \sin a - (\cos a) \cdot h|}{|(h, k)|}. \end{aligned}$$

Since $\sin'(a) = \cos a$, we have

$$\lim_{h \rightarrow 0} \frac{|\sin(a+h) - \sin a - (\cos a) \cdot h|}{|h|} = 0.$$

Since $|(h, k)| \geq |h|$, it is also true that

$$\lim_{h \rightarrow 0} \frac{|\sin(a+h) - \sin a - (\cos a) \cdot h|}{|(h, k)|} = 0.$$

It is often convenient to consider the matrix of $Df(a)$: $\mathbf{R}^n \rightarrow \mathbf{R}^m$ with respect to the usual bases of \mathbf{R}^n and \mathbf{R}^m . This $m \times n$ matrix is called the **Jacobian matrix** of f at a , and denoted $f'(a)$. If $f(x, y) = \sin x$, then $f'(a, b) = (\cos a, 0)$. If $f: \mathbf{R} \rightarrow \mathbf{R}$, then $f'(a)$ is a 1×1 matrix whose single entry is the number which is denoted $f'(a)$ in elementary calculus.

The definition of $Df(a)$ could be made if f were defined only in some open set containing a . Considering only functions defined on \mathbf{R}^n streamlines the statement of theorems and produces no real loss of generality. It is convenient to define a function $f: \mathbf{R}^n \rightarrow \mathbf{R}^m$ to be differentiable on A if f is differentiable at a for each $a \in A$. If $f: A \rightarrow \mathbf{R}^m$, then f is called differentiable if f can be extended to a differentiable function on some open set containing A .

Problems. 2-1.* Prove that if $f: \mathbf{R}^n \rightarrow \mathbf{R}^m$ is differentiable at $a \in \mathbf{R}^n$, then it is continuous at a . *Hint:* Use Problem 1-10.

2-2. A function $f: \mathbf{R}^2 \rightarrow \mathbf{R}$ is **independent of the second variable** if for each $x \in \mathbf{R}$ we have $f(x, y_1) = f(x, y_2)$ for all $y_1, y_2 \in \mathbf{R}$. Show that f is independent of the second variable if and only if there is a function $g: \mathbf{R} \rightarrow \mathbf{R}$ such that $f(x, y) = g(x)$. What is $f'(a, b)$ in terms of g' ?

- 2-3.** Define when a function $f: \mathbf{R}^2 \rightarrow \mathbf{R}$ is independent of the first variable and find $f'(a,b)$ for such f . Which functions are independent of the first variable and also of the second variable?
- 2-4.** Let g be a continuous real-valued function on the unit circle $\{x \in \mathbf{R}^2: |x| = 1\}$ such that $g(0,1) = g(1,0) = 0$ and $g(-x) = -g(x)$. Define $f: \mathbf{R}^2 \rightarrow \mathbf{R}$ by

$$f(x) = \begin{cases} |x| \cdot g\left(\frac{x}{|x|}\right) & x \neq 0, \\ 0 & x = 0. \end{cases}$$

- (a) If $x \in \mathbf{R}^2$ and $h: \mathbf{R} \rightarrow \mathbf{R}$ is defined by $h(t) = f(tx)$, show that h is differentiable.
- (b) Show that f is not differentiable at $(0,0)$ unless $g = 0$.
Hint: First show that $Df(0,0)$ would have to be 0 by considering (h,k) with $k = 0$ and then with $h = 0$.
- 2-5.** Let $f: \mathbf{R}^2 \rightarrow \mathbf{R}$ be defined by

$$f(x,y) = \begin{cases} \frac{x|y|}{\sqrt{x^2 + y^2}} & (x,y) \neq 0, \\ 0 & (x,y) = 0. \end{cases}$$

Show that f is a function of the kind considered in Problem 2-4, so that f is not differentiable at $(0,0)$.

- 2-6.** Let $f: \mathbf{R}^2 \rightarrow \mathbf{R}$ be defined by $f(x,y) = \sqrt{|xy|}$. Show that f is not differentiable at $(0,0)$.
- 2-7.** Let $f: \mathbf{R}^n \rightarrow \mathbf{R}$ be a function such that $|f(x)| \leq |x|^2$. Show that f is differentiable at 0.
- 2-8.** Let $f: \mathbf{R} \rightarrow \mathbf{R}^2$. Prove that f is differentiable at $a \in \mathbf{R}$ if and only if f^1 and f^2 are, and that in this case

$$f'(a) = \begin{pmatrix} (f^1)'(a) \\ (f^2)'(a) \end{pmatrix}.$$

- 2-9.** Two functions $f, g: \mathbf{R} \rightarrow \mathbf{R}$ are **equal up to n th order** at a if

$$\lim_{h \rightarrow 0} \frac{f(a+h) - g(a+h)}{h^n} = 0.$$

(a) Show that f is differentiable at a if and only if there is a function g of the form $g(x) = a_0 + a_1(x-a)$ such that f and g are equal up to first order at a .

(b) If $f'(a), \dots, f^{(n)}(a)$ exist, show that f and the function g defined by

$$g(x) = \sum_{i=0}^n \frac{f^{(i)}(a)}{i!} (x-a)^i$$

are equal up to n th order at a . *Hint:* The limit

$$\lim_{x \rightarrow a} \frac{f(x) - \sum_{i=0}^{n-1} \frac{f^{(i)}(a)}{i!} (x-a)^i}{(x-a)^n}$$

may be evaluated by L'Hospital's rule.

BASIC THEOREMS

2-2 Theorem (Chain Rule). *If $f: \mathbf{R}^n \rightarrow \mathbf{R}^m$ is differentiable at a , and $g: \mathbf{R}^m \rightarrow \mathbf{R}^p$ is differentiable at $f(a)$, then the composition $g \circ f: \mathbf{R}^n \rightarrow \mathbf{R}^p$ is differentiable at a , and*

$$D(g \circ f)(a) = Dg(f(a)) \circ Df(a).$$

Remark. This equation can be written

$$(g \circ f)'(a) = g'(f(a)) \cdot f'(a).$$

If $m = n = p = 1$, we obtain the old chain rule.

Proof. Let $b = f(a)$, let $\lambda = Df(a)$, and let $\mu = Dg(f(a))$. If we define

- (1) $\varphi(x) = f(x) - f(a) - \lambda(x-a)$,
- (2) $\psi(y) = g(y) - g(b) - \mu(y-b)$,
- (3) $\rho(x) = g \circ f(x) - g \circ f(a) - \mu \circ \lambda(x-a)$,

then

$$(4) \lim_{x \rightarrow a} \frac{|\varphi(x)|}{|x-a|} = 0,$$

$$(5) \lim_{y \rightarrow b} \frac{|\psi(y)|}{|y-b|} = 0,$$

and we must show that

$$\lim_{x \rightarrow a} \frac{|\rho(x)|}{|x-a|} = 0.$$

Now

$$\begin{aligned} \rho(x) &= g(f(x)) - g(b) - \mu(\lambda(x-a)) \\ &= g(f(x)) - g(b) - \mu(f(x) - f(a) - \varphi(x)) \quad \text{by (1)} \\ &= [g(f(x)) - g(b) - \mu(f(x) - f(a))] + \mu(\varphi(x)) \\ &= \psi(f(x)) + \mu(\varphi(x)) \quad \text{by (2)}. \end{aligned}$$

Thus we must prove

$$(6) \lim_{x \rightarrow a} \frac{|\psi(f(x))|}{|x - a|} = 0,$$

$$(7) \lim_{x \rightarrow a} \frac{|\mu(\varphi(x))|}{|x - a|} = 0.$$

Equation (7) follows easily from (4) and Problem 1-10. If $\varepsilon > 0$ it follows from (5) that for some $\delta > 0$ we have

$$|\psi(f(x))| < \varepsilon |f(x) - b| \quad \text{if } |f(x) - b| < \delta,$$

which is true if $|x - a| < \delta_1$, for a suitable δ_1 . Then

$$\begin{aligned} |\psi(f(x))| &< \varepsilon |f(x) - b| \\ &= \varepsilon |\varphi(x) + \lambda(x - a)| \\ &\leq \varepsilon |\varphi(x)| + \varepsilon M |x - a| \end{aligned}$$

for some M , by Problem 1-10. Equation (6) now follows easily. ■

2-3 Theorem

(1) If $f: \mathbf{R}^n \rightarrow \mathbf{R}^m$ is a constant function (that is, if for some $y \in \mathbf{R}^m$ we have $f(x) = y$ for all $x \in \mathbf{R}^n$), then

$$Df(a) = 0.$$

(2) If $f: \mathbf{R}^n \rightarrow \mathbf{R}^m$ is a linear transformation, then

$$Df(a) = f.$$

(3) If $f: \mathbf{R}^n \rightarrow \mathbf{R}^m$, then f is differentiable at $a \in \mathbf{R}^n$ if and only if each f^i is, and

$$Df(a) = (Df^1(a), \dots, Df^m(a)).$$

Thus $f'(a)$ is the $m \times n$ matrix whose i th row is $(f^i)'(a)$.

(4) If $s: \mathbf{R}^2 \rightarrow \mathbf{R}$ is defined by $s(x, y) = x + y$, then

$$Ds(a, b) = s.$$

(5) If $p: \mathbf{R}^2 \rightarrow \mathbf{R}$ is defined by $p(x, y) = x \cdot y$, then

$$Dp(a, b)(x, y) = bx + ay.$$

Thus $p'(a, b) = (b, a)$.

Proof

$$(1) \lim_{h \rightarrow 0} \frac{|f(a+h) - f(a) - 0|}{|h|} = \lim_{h \rightarrow 0} \frac{|y - y - 0|}{|h|} = 0.$$

$$(2) \lim_{h \rightarrow 0} \frac{|f(a+h) - f(a) - f(h)|}{|h|} \\ = \lim_{h \rightarrow 0} \frac{|f(a) + f(h) - f(a) - f(h)|}{|h|} = 0.$$

(3) If each f^i is differentiable at a and

$$\lambda = (Df^1(a), \dots, Df^m(a)),$$

then

$$\begin{aligned} f(a+h) - f(a) - \lambda(h) \\ = (f^1(a+h) - f^1(a) - Df^1(a)(h), \dots, \\ f^m(a+h) - f^m(a) - Df^m(a)(h)). \end{aligned}$$

Therefore

$$\begin{aligned} \lim_{h \rightarrow 0} \frac{|f(a+h) - f(a) - \lambda(h)|}{|h|} \\ \leq \lim_{h \rightarrow 0} \sum_{i=1}^m \frac{|f^i(a+h) - f^i(a) - Df^i(a)(h)|}{|h|} = 0. \end{aligned}$$

If, on the other hand, f is differentiable at a , then $f^i = \pi^i \circ f$ is differentiable at a by (2) and Theorem 2-2.

(4) follows from (2).

(5) Let $\lambda(x,y) = bx + ay$. Then

$$\begin{aligned} \lim_{(h,k) \rightarrow 0} \frac{|p(a+h, b+k) - p(a,b) - \lambda(h,k)|}{|(h,k)|} \\ = \lim_{(h,k) \rightarrow 0} \frac{|hk|}{|(h,k)|}. \end{aligned}$$

Now

$$|hk| \leq \begin{cases} |h|^2 & \text{if } |k| \leq |h|, \\ |k|^2 & \text{if } |h| \leq |k|. \end{cases}$$

Hence $|hk| \leq |h|^2 + |k|^2$. Therefore

$$\frac{|hk|}{|(h,k)|} \leq \frac{h^2 + k^2}{\sqrt{h^2 + k^2}} = \sqrt{h^2 + k^2},$$

so

$$\lim_{(h,k) \rightarrow 0} \frac{|hk|}{|(h,k)|} = 0. \quad \blacksquare$$

2-4 Corollary. If $f, g: \mathbf{R}^n \rightarrow \mathbf{R}$ are differentiable at a , then

$$\begin{aligned} D(f + g)(a) &= Df(a) + Dg(a), \\ D(f \cdot g)(a) &= g(a)Df(a) + f(a)Dg(a). \end{aligned}$$

If, moreover, $g(a) \neq 0$, then

$$D(f/g)(a) = \frac{g(a)Df(a) - f(a)Dg(a)}{[g(a)]^2}.$$

Proof. We will prove the first equation and leave the others to the reader. Since $f + g = s \circ (f, g)$, we have

$$\begin{aligned} D(f + g)(a) &= Ds(f(a), g(a)) \circ D(f, g)(a) \\ &= s \circ (Df(a), Dg(a)) \\ &= Df(a) + Dg(a). \quad \blacksquare \end{aligned}$$

We are now assured of the differentiability of those functions $f: \mathbf{R}^n \rightarrow \mathbf{R}^m$, whose component functions are obtained by addition, multiplication, division, and composition, from the functions π^i (which are linear transformations) and the functions which we can already differentiate by elementary calculus. Finding $Df(x)$ or $f'(x)$, however, may be a fairly formidable task. For example, let $f: \mathbf{R}^2 \rightarrow \mathbf{R}$ be defined by $f(x, y) = \sin(xy^2)$. Since $f = \sin \circ (\pi^1 \cdot [\pi^2]^2)$, we have

$$\begin{aligned} f'(a, b) &= \sin'(ab^2) \cdot [b^2(\pi^1)'(a, b) + a([\pi^2]^2)'(a, b)] \\ &= \sin'(ab^2) \cdot [b^2(\pi^1)'(a, b) + 2ab(\pi^2)'(a, b)] \\ &= (\cos(ab^2)) \cdot [b^2(1, 0) + 2ab(0, 1)] \\ &= (b^2 \cos(ab^2), 2ab \cos(ab^2)). \end{aligned}$$

Fortunately, we will soon discover a much simpler method of computing f' .

Problems. 2-10. Use the theorems of this section to find f' for the following:

- (a) $f(x, y, z) = x^y$.
- (b) $f(x, y, z) = (x^y, z)$.
- (c) $f(x, y) = \sin(x \sin y)$.
- (d) $f(x, y, z) = \sin(x \sin(y \sin z))$.
- (e) $f(x, y, z) = x^{y^z}$.
- (f) $f(x, y, z) = x^{y+z}$.
- (g) $f(x, y, z) = (x + y)^z$.
- (h) $f(x, y) = \sin(xy)$.
- (i) $f(x, y) = [\sin(xy)]^{\cos z}$.
- (j) $f(x, y) = (\sin(xy), \sin(x \sin y), x^y)$.

2-11. Find f' for the following (where $g: \mathbf{R} \rightarrow \mathbf{R}$ is continuous):

- (a) $f(x, y) = \int_a^{x+y} g$.
- (b) $f(x, y) = \int_a^{x \cdot y} g$.
- (c) $f(x, y, z) = \int_{xy}^{\sin(x \sin(y \sin z))} g$.

2-12. A function $f: \mathbf{R}^n \times \mathbf{R}^m \rightarrow \mathbf{R}^p$ is **bilinear** if for $x, x_1, x_2 \in \mathbf{R}^n$, $y, y_1, y_2 \in \mathbf{R}^m$, and $a \in \mathbf{R}$ we have

$$\begin{aligned} f(ax, y) &= af(x, y) = f(x, ay), \\ f(x_1 + x_2, y) &= f(x_1, y) + f(x_2, y), \\ f(x, y_1 + y_2) &= f(x, y_1) + f(x, y_2). \end{aligned}$$

(a) Prove that if f is bilinear, then

$$\lim_{(h, k) \rightarrow 0} \frac{|f(h, k)|}{|(h, k)|} = 0.$$

(b) Prove that $Df(a, b)(x, y) = f(a, y) + f(x, b)$.

(c) Show that the formula for $Dp(a, b)$ in Theorem 2-3 is a special case of (b).

2-13. Define $IP: \mathbf{R}^n \times \mathbf{R}^n \rightarrow \mathbf{R}$ by $IP(x, y) = \langle x, y \rangle$.

- (a) Find $D(IP)(a, b)$ and $(IP)'(a, b)$.
- (b) If $f, g: \mathbf{R} \rightarrow \mathbf{R}^n$ are differentiable and $h: \mathbf{R} \rightarrow \mathbf{R}$ is defined by $h(t) = \langle f(t), g(t) \rangle$, show that

$$h'(a) = \langle f'(a)^T, g(a) \rangle + \langle f(a), g'(a)^T \rangle.$$

(Note that $f'(a)$ is an $n \times 1$ matrix; its transpose $f'(a)^T$ is a $1 \times n$ matrix, which we consider as a member of \mathbf{R}^n .)

(c) If $f: \mathbf{R} \rightarrow \mathbf{R}^n$ is differentiable and $|f(t)| = 1$ for all t , show that $\langle f'(t)^T, f(t) \rangle = 0$.

(d) Exhibit a differentiable function $f: \mathbf{R} \rightarrow \mathbf{R}$ such that the function $|f|$ defined by $|f|(t) = |f(t)|$ is not differentiable.

2-14. Let E_i , $i = 1, \dots, k$ be Euclidean spaces of various dimensions. A function $f: E_1 \times \dots \times E_k \rightarrow \mathbf{R}^p$ is called **multilinear** if for each choice of $x_j \in E_j$, $j \neq i$ the function $g: E_i \rightarrow \mathbf{R}^p$ defined by $g(x) = f(x_1, \dots, x_{i-1}, x, x_{i+1}, \dots, x_k)$ is a linear transformation.

(a) If f is multilinear and $i \neq j$, show that for $h = (h_1, \dots, h_k)$, with $h_l \in E_l$, we have

$$\lim_{h \rightarrow 0} \frac{|f(a_1, \dots, h_i, \dots, h_j, \dots, a_k)|}{|h|} = 0.$$

Hint: If $g(x, y) = f(a_1, \dots, x, \dots, y, \dots, a_k)$, then g is bilinear.

(b) Prove that

$$Df(a_1, \dots, a_k)(x_1, \dots, x_k) = \sum_{i=1}^k f(a_1, \dots, a_{i-1}, x_i, a_{i+1}, \dots, a_k).$$

2-15. Regard an $n \times n$ matrix as a point in the n -fold product $\mathbf{R}^n \times \dots \times \mathbf{R}^n$ by considering each row as a member of \mathbf{R}^n .

(a) Prove that $\det: \mathbf{R}^n \times \dots \times \mathbf{R}^n \rightarrow \mathbf{R}$ is differentiable and

$$D(\det)(a_1, \dots, a_n)(x_1, \dots, x_n) = \sum_{i=1}^n \det \begin{pmatrix} a_1 \\ \vdots \\ x_i \\ \vdots \\ a_n \end{pmatrix}.$$

(b) If $a_{ij}: \mathbf{R} \rightarrow \mathbf{R}$ are differentiable and $f(t) = \det(a_{ij}(t))$, show that

$$f'(t) = \sum_{j=1}^n \det \begin{pmatrix} a_{11}(t), \dots, a_{1n}(t) \\ \vdots \\ a_{j1}'(t), \dots, a_{jn}'(t) \\ \vdots \\ a_{n1}(t), \dots, a_{nn}(t) \end{pmatrix}.$$

(c) If $\det(a_{ij}(t)) \neq 0$ for all t and $b_1, \dots, b_n: \mathbf{R} \rightarrow \mathbf{R}$ are differentiable, let $s_1, \dots, s_n: \mathbf{R} \rightarrow \mathbf{R}$ be the functions such that $s_1(t), \dots, s_n(t)$ are the solutions of the equations

$$\sum_{j=1}^n a_{ji}(t)s_j(t) = b_i(t) \quad i = 1, \dots, n.$$

Show that s_i is differentiable and find $s_i'(t)$.

- 2-16.** Suppose $f: \mathbf{R}^n \rightarrow \mathbf{R}^n$ is differentiable and has a differentiable inverse $f^{-1}: \mathbf{R}^n \rightarrow \mathbf{R}^n$. Show that $(f^{-1})'(a) = [f'(f^{-1}(a))]^{-1}$.
Hint: $f \circ f^{-1}(x) = x$.

PARTIAL DERIVATIVES

We begin the attack on the problem of finding derivatives “one variable at a time.” If $f: \mathbf{R}^n \rightarrow \mathbf{R}$ and $a \in \mathbf{R}^n$, the limit

$$\lim_{h \rightarrow 0} \frac{f(a^1, \dots, a^i + h, \dots, a^n) - f(a^1, \dots, a^n)}{h},$$

if it exists, is denoted $D_i f(a)$, and called the i th **partial derivative** of f at a . It is important to note that $D_i f(a)$ is the ordinary derivative of a certain function; in fact, if $g(x) = f(a^1, \dots, x, \dots, a^n)$, then $D_i f(a) = g'(a^i)$. This means that $D_i f(a)$ is the slope of the tangent line at $(a, f(a))$ to the curve obtained by intersecting the graph of f with the plane $x^j = a^j, j \neq i$ (Figure 2-1). It also means that computation of $D_i f(a)$ is a problem we can already solve. If $f(x^1, \dots, x^n)$ is

FIGURE 2-1

given by some formula involving x^1, \dots, x^n , then we find $D_i f(x^1, \dots, x^n)$ by differentiating the function whose value at x^i is given by the formula when all x^j , for $j \neq i$, are thought of as constants. For example, if $f(x, y) = \sin(xy^2)$, then $D_1 f(x, y) = y^2 \cos(xy^2)$ and $D_2 f(x, y) = 2xy \cos(xy^2)$. If, instead, $f(x, y) = x^y$, then $D_1 f(x, y) = yx^{y-1}$ and $D_2 f(x, y) = x^y \log x$.

With a little practice (e.g., the problems at the end of this section) you should acquire as great a facility for computing $D_i f$ as you already have for computing ordinary derivatives.

If $D_i f(x)$ exists for all $x \in \mathbf{R}^n$, we obtain a function $D_i f: \mathbf{R}^n \rightarrow \mathbf{R}$. The j th partial derivative of this function at x , that is, $D_j(D_i f)(x)$, is often denoted $D_{i,j} f(x)$. Note that this notation reverses the order of i and j . As a matter of fact, the order is usually irrelevant, since most functions (an exception is given in the problems) satisfy $D_{i,j} f = D_{j,i} f$. There are various delicate theorems ensuring this equality; the following theorem is quite adequate. We state it here but postpone the proof until later (Problem 3-28).

2-5 Theorem. *If $D_{i,j} f$ and $D_{j,i} f$ are continuous in an open set containing a , then*

$$D_{i,j} f(a) = D_{j,i} f(a).$$

The function $D_{i,j} f$ is called a **second-order (mixed) partial derivative** of f . Higher-order (mixed) partial derivatives are defined in the obvious way. Clearly Theorem 2-5 can be used to prove the equality of higher-order mixed partial derivatives under appropriate conditions. The order of i_1, \dots, i_k is completely immaterial in $D_{i_1, \dots, i_k} f$ if f has continuous partial derivatives of all orders. A function with this property is called a C^∞ function. In later chapters it will frequently be convenient to restrict our attention to C^∞ functions.

Partial derivatives will be used in the next section to find derivatives. They also have another important use—finding maxima and minima of functions.

2-6 Theorem. Let $A \subset \mathbf{R}^n$. If the maximum (or minimum) of $f: A \rightarrow \mathbf{R}$ occurs at a point a in the interior of A and $D_i f(a)$ exists, then $D_i f(a) = 0$.

Proof. Let $g_i(x) = f(a^1, \dots, x, \dots, a^n)$. Clearly g_i has a maximum (or minimum) at a^i , and g_i is defined in an open interval containing a^i . Hence $0 = g_i'(a^i) = D_i f(a)$. ■

The reader is reminded that the converse of Theorem 2-6 is false even if $n = 1$ (if $f: \mathbf{R} \rightarrow \mathbf{R}$ is defined by $f(x) = x^3$, then $f'(0) = 0$, but 0 is not even a local maximum or minimum). If $n > 1$, the converse of Theorem 2-6 may fail to be true in a rather spectacular way. Suppose, for example, that $f: \mathbf{R}^2 \rightarrow \mathbf{R}$ is defined by $f(x, y) = x^2 - y^2$ (Figure 2-2). Then $D_1 f(0, 0) = 0$ because g_1 has a minimum at 0, while $D_2 f(0, 0) = 0$ because g_2 has a maximum at 0. Clearly $(0, 0)$ is neither a relative maximum nor a relative minimum.

FIGURE 2-2

If Theorem 2-6 is used to find the maximum or minimum of f on A , the values of f at boundary points must be examined separately—a formidable task, since the boundary of A may be all of A ! Problem 2-27 indicates one way of doing this, and Problem 5-16 states a superior method which can often be used.

Problems. 2-17. Find the partial derivatives of the following functions:

- (a) $f(x, y, z) = x^y$.
- (b) $f(x, y, z) = z$.
- (c) $f(x, y) = \sin(x \sin y)$.
- (d) $f(x, y, z) = \sin(x \sin(y \sin z))$.
- (e) $f(x, y, z) = x^{y^z}$.
- (f) $f(x, y, z) = x^{y+z}$.
- (g) $f(x, y, z) = (x + y)^z$.
- (h) $f(x, y) = \sin(xy)$.
- (i) $f(x, y) = \{\sin(xy)\}^{\cos z}$.

2-18. Find the partial derivatives of the following functions (where $g: \mathbf{R} \rightarrow \mathbf{R}$ is continuous):

- (a) $f(x, y) = \int_a^{x+y} g$.
- (b) $f(x, y) = \int_y^x g$.
- (c) $f(x, y) = \int_a^{xy} g$.
- (d) $f(x, y) = \int_a^{\left(\int_b^y g\right)} g$.

2-19. If $f(x, y) = x^{x^{xy}} + (\log x)(\arctan(\arctan(\arctan(\sin(\cos xy) - \log(x + y))))))$ find $D_2f(1, y)$. *Hint:* There is an easy way to do this.

2-20. Find the partial derivatives of f in terms of the derivatives of g and h if

- (a) $f(x, y) = g(x)h(y)$.
- (b) $f(x, y) = g(x)^{h(y)}$.
- (c) $f(x, y) = g(x)$.
- (d) $f(x, y) = g(y)$.
- (e) $f(x, y) = g(x + y)$.

2-21.* Let $g_1, g_2: \mathbf{R}^2 \rightarrow \mathbf{R}$ be continuous. Define $f: \mathbf{R}^2 \rightarrow \mathbf{R}$ by

$$f(x, y) = \int_0^x g_1(t, 0) dt + \int_0^y g_2(x, t) dt.$$

- (a) Show that $D_2f(x, y) = g_2(x, y)$.
- (b) How should f be defined so that $D_1f(x, y) = g_1(x, y)$?
- (c) Find a function $f: \mathbf{R}^2 \rightarrow \mathbf{R}$ such that $D_1f(x, y) = x$ and $D_2f(x, y) = y$. Find one such that $D_1f(x, y) = y$ and $D_2f(x, y) = x$.

2-22.* If $f: \mathbf{R}^2 \rightarrow \mathbf{R}$ and $D_2f = 0$, show that f is independent of the second variable. If $D_1f = D_2f = 0$, show that f is constant.

2-23.* Let $A = \{(x, y) \in \mathbf{R}^2: x < 0, \text{ or } x \geq 0 \text{ and } y \neq 0\}$.

(a) If $f: A \rightarrow \mathbf{R}$ and $D_1f = D_2f = 0$, show that f is constant.

Hint: Note that any two points in A can be connected by a sequence of lines each parallel to one of the axes.

(b) Find a function $f: A \rightarrow \mathbf{R}$ such that $D_2f = 0$ but f is not independent of the second variable.

2-24. Define $f: \mathbf{R}^2 \rightarrow \mathbf{R}$ by

$$f(x, y) = \begin{cases} xy \frac{x^2 - y^2}{x^2 + y^2} & (x, y) \neq 0, \\ 0 & (x, y) = 0. \end{cases}$$

(a) Show that $D_2f(x, 0) = x$ for all x and $D_1f(0, y) = -y$ for all y .

(b) Show that $D_{1,2}f(0, 0) \neq D_{2,1}f(0, 0)$.

2-25.* Define $f: \mathbf{R} \rightarrow \mathbf{R}$ by

$$f(x) = \begin{cases} e^{-x^{-2}} & x \neq 0, \\ 0 & x = 0. \end{cases}$$

Show that f is a C^∞ function, and $f^{(i)}(0) = 0$ for all i . *Hint:*

The limit $f'(0) = \lim_{h \rightarrow 0} \frac{e^{-h^{-2}}}{h} = \lim_{h \rightarrow 0} \frac{1/h}{e^{h^{-2}}}$ can be evaluated by

L'Hospital's rule. It is easy enough to find $f'(x)$ for $x \neq 0$, and $f''(0) = \lim_{h \rightarrow 0} f'(h)/h$ can then be found by L'Hospital's rule.

2-26.* Let $f(x) = \begin{cases} e^{-(x-1)^{-2}} \cdot e^{-(x+1)^{-2}} & x \in (-1, 1), \\ 0 & x \notin (-1, 1). \end{cases}$

(a) Show that $f: \mathbf{R} \rightarrow \mathbf{R}$ is a C^∞ function which is positive on $(-1, 1)$ and 0 elsewhere.

(b) Show that there is a C^∞ function $g: \mathbf{R} \rightarrow [0, 1]$ such that $g(x) = 0$ for $x \leq 0$ and $g(x) = 1$ for $x \geq \varepsilon$. *Hint:* If f is a C^∞ function which is positive on $(0, \varepsilon)$ and 0 elsewhere, let $g(x) = \int_0^x f / \int_0^\varepsilon f$.

(c) If $a \in \mathbf{R}^n$, define $g: \mathbf{R}^n \rightarrow \mathbf{R}$ by

$$g(x) = f([x^1 - a^1]/\varepsilon) \cdot \dots \cdot f([x^n - a^n]/\varepsilon).$$

Show that g is a C^∞ function which is positive on

$$(a^1 - \varepsilon, a^1 + \varepsilon) \times \dots \times (a^n - \varepsilon, a^n + \varepsilon)$$

and zero elsewhere.

(d) If $A \subset \mathbf{R}^n$ is open and $C \subset A$ is compact, show that there is a non-negative C^∞ function $f: A \rightarrow \mathbf{R}$ such that $f(x) > 0$ for $x \in C$ and $f = 0$ outside of some closed set contained in A .

(e) Show that we can choose such an f so that $f: A \rightarrow [0, 1]$ and $f(x) = 1$ for $x \in C$. *Hint:* If the function f of (d) satisfies $f(x) \geq \varepsilon$ for $x \in C$, consider $g \circ f$, where g is the function of (b).

2-27. Define $g, h: \{x \in \mathbf{R}^2: |x| \leq 1\} \rightarrow \mathbf{R}^3$ by

$$\begin{aligned} g(x, y) &= (x, y, \sqrt{1 - x^2 - y^2}), \\ h(x, y) &= (x, y, -\sqrt{1 - x^2 - y^2}). \end{aligned}$$

Show that the maximum of f on $\{x \in \mathbf{R}^2: |x| = 1\}$ is either the maximum of $f \circ g$ or the maximum of $f \circ h$ on $\{x \in \mathbf{R}^2: |x| \leq 1\}$.

DERIVATIVES

The reader who has compared Problems 2-10 and 2-17 has probably already guessed the following.

2-7 Theorem. *If $f: \mathbf{R}^n \rightarrow \mathbf{R}^m$ is differentiable at a , then $D_j f^i(a)$ exists for $1 \leq i \leq m$, $1 \leq j \leq n$ and $f'(a)$ is the $m \times n$ matrix $(D_j f^i(a))$.*

Proof. Suppose first that $m = 1$, so that $f: \mathbf{R}^n \rightarrow \mathbf{R}$. Define $h: \mathbf{R} \rightarrow \mathbf{R}^n$ by $h(x) = (a^1, \dots, x, \dots, a^n)$, with x in the j th place. Then $D_j f(a) = (f \circ h)'(a^j)$. Hence, by Theorem 2-2,

$$\begin{aligned} (f \circ h)'(a^j) &= f'(a) \cdot h'(a^j) \\ &= f'(a) \cdot \begin{pmatrix} 0 \\ \vdots \\ 1 \\ \vdots \\ 0 \end{pmatrix} \leftarrow j\text{th place.} \end{aligned}$$

Since $(f \circ h)'(a^j)$ has the single entry $D_j f(a)$, this shows that $D_j f(a)$ exists and is the j th entry of the $1 \times n$ matrix $f'(a)$.

The theorem now follows for arbitrary m since, by Theorem 2-3, each f^i is differentiable and the i th row of $f'(a)$ is $(f^i)'(a)$. ■

There are several examples in the problems to show that the converse of Theorem 2-7 is false. It is true, however, if one hypothesis is added.

2-8 Theorem. If $f: \mathbf{R}^n \rightarrow \mathbf{R}^m$, then $Df(a)$ exists if all $D_j f^i(x)$ exist in an open set containing a and if each function $D_j f^i$ is continuous at a .

(Such a function f is called **continuously differentiable** at a .)

Proof. As in the proof of Theorem 2-7, it suffices to consider the case $m = 1$, so that $f: \mathbf{R}^n \rightarrow \mathbf{R}$. Then

$$\begin{aligned} f(a + h) - f(a) &= f(a^1 + h^1, a^2, \dots, a^n) - f(a^1, \dots, a^n) \\ &\quad + f(a^1 + h^1, a^2 + h^2, a^3, \dots, a^n) \\ &\quad \quad - f(a^1 + h^1, a^2, \dots, a^n) \\ &\quad + \dots \\ &\quad + f(a^1 + h^1, \dots, a^{n-1} + h^{n-1}, a^n) \\ &\quad \quad - f(a^1 + h^1, \dots, a^{n-1}, a^n). \end{aligned}$$

Recall that $D_1 f$ is the derivative of the function g defined by $g(x) = f(x, a^2, \dots, a^n)$. Applying the mean-value theorem to g we obtain

$$\begin{aligned} f(a^1 + h^1, a^2, \dots, a^n) - f(a^1, \dots, a^n) \\ = h^1 \cdot D_1 f(b_1, a^2, \dots, a^n) \end{aligned}$$

for some b_1 between a^1 and $a^1 + h^1$. Similarly the i th term in the sum equals

$$h^i \cdot D_i f(a^1 + h^1, \dots, a^{i-1} + h^{i-1}, b_i, \dots, a^n) = h^i D_i f(c_i),$$

for some c_i . Then

$$\begin{aligned} \lim_{h \rightarrow 0} \frac{\left| f(a + h) - f(a) - \sum_{i=1}^n D_i f(a) \cdot h^i \right|}{|h|} \\ = \lim_{h \rightarrow 0} \frac{\left| \sum_{i=1}^n [D_i f(c_i) - D_i f(a)] \cdot h^i \right|}{|h|} \\ \leq \lim_{h \rightarrow 0} \sum_{i=1}^n |D_i f(c_i) - D_i f(a)| \cdot \frac{|h^i|}{|h|} \\ \leq \lim_{h \rightarrow 0} \sum_{i=1}^n |D_i f(c_i) - D_i f(a)| \\ = 0, \end{aligned}$$

since $D_i f$ is continuous at a . ■

Although the chain rule was used in the proof of Theorem 2-7, it could easily have been eliminated. With Theorem 2-8 to provide differentiable functions, and Theorem 2-7 to provide their derivatives, the chain rule may therefore seem almost superfluous. However, it has an extremely important corollary concerning partial derivatives.

2-9 Theorem. Let $g_1, \dots, g_m: \mathbf{R}^n \rightarrow \mathbf{R}$ be continuously differentiable at a , and let $f: \mathbf{R}^m \rightarrow \mathbf{R}$ be differentiable at $(g_1(a), \dots, g_m(a))$. Define the function $F: \mathbf{R}^n \rightarrow \mathbf{R}$ by $F(x) = f(g_1(x), \dots, g_m(x))$. Then

$$D_i F(a) = \sum_{j=1}^m D_j f(g_1(a), \dots, g_m(a)) \cdot D_i g_j(a).$$

Proof. The function F is just the composition $f \circ g$, where $g = (g_1, \dots, g_m)$. Since g_i is continuously differentiable at a , it follows from Theorem 2-8 that g is differentiable at a . Hence by Theorem 2-2,

$$F'(a) = f'(g(a)) \cdot g'(a) = (D_1 f(g(a)), \dots, D_m f(g(a))) \cdot \begin{pmatrix} D_1 g_1(a), & \dots, & D_n g_1(a) \\ \vdots & & \vdots \\ D_1 g_m(a), & \dots, & D_n g_m(a) \end{pmatrix}$$

But $D_i F(a)$ is the i th entry of the left side of this equation, while $\sum_{j=1}^m D_j f(g_1(a), \dots, g_m(a)) \cdot D_i g_j(a)$ is the i th entry of the right side. ■

Theorem 2-9 is often called the *chain rule*, but is weaker than Theorem 2-2 since g could be differentiable without g_i being continuously differentiable (see Problem 2-32). Most computations requiring Theorem 2-9 are fairly straightforward. A slight subtlety is required for the function $F: \mathbf{R}^2 \rightarrow \mathbf{R}$ defined by

$$F(x, y) = f(g(x, y), h(x), k(y))$$

where $h, k: \mathbf{R} \rightarrow \mathbf{R}$. In order to apply Theorem 2-9 define $\bar{h}, \bar{k}: \mathbf{R}^2 \rightarrow \mathbf{R}$ by

$$\bar{h}(x, y) = h(x) \quad \bar{k}(x, y) = k(y).$$

Then

$$\begin{aligned} D_1 \bar{h}(x, y) &= h'(x) & D_2 \bar{h}(x, y) &= 0, \\ D_1 \bar{k}(x, y) &= 0 & D_2 \bar{k}(x, y) &= k'(y), \end{aligned}$$

and we can write

$$F(x, y) = f(g(x, y), \bar{h}(x, y), \bar{k}(x, y)).$$

Letting $a = (g(x, y), h(x), k(y))$, we obtain

$$\begin{aligned} D_1 F(x, y) &= D_1 f(a) \cdot D_1 g(x, y) + D_2 f(a) \cdot h'(x), \\ D_2 F(x, y) &= D_1 f(a) \cdot D_2 g(x, y) + D_3 f(a) \cdot k'(y). \end{aligned}$$

It should, of course, be unnecessary for you to actually write down the functions \bar{h} and \bar{k} .

Problems. 2-28. Find expressions for the partial derivatives of the following functions:

- (a) $F(x, y) = f(g(x)k(y), g(x) + h(y))$.
- (b) $F(x, y, z) = f(g(x + y), h(y + z))$.
- (c) $F(x, y, z) = f(x^y, y^z, z^x)$.
- (d) $F(x, y) = f(x, g(x), h(x, y))$.

2-29. Let $f: \mathbf{R}^n \rightarrow \mathbf{R}$. For $x \in \mathbf{R}^n$, the limit

$$\lim_{t \rightarrow 0} \frac{f(a + tx) - f(a)}{t},$$

if it exists, is denoted $D_x f(a)$, and called the **directional derivative** of f at a , in the direction x .

- (a) Show that $D_{e_i} f(a) = D_i f(a)$.
 - (b) Show that $D_{tx} f(a) = t D_x f(a)$.
 - (c) If f is differentiable at a , show that $D_x f(a) = Df(a)(x)$ and therefore $D_{x+y} f(a) = D_x f(a) + D_y f(a)$.
- 2-30.** Let f be defined as in Problem 2-4. Show that $D_x f(0, 0)$ exists for all x , but if $g \neq 0$, then $D_{x+y} f(0, 0) = D_x f(0, 0) + D_y f(0, 0)$ is not true for all x and y .
- 2-31.** Let $f: \mathbf{R}^2 \rightarrow \mathbf{R}$ be defined as in Problem 1-26. Show that $D_x f(0, 0)$ exists for all x , although f is not even continuous at $(0, 0)$.
- 2-32.** (a) Let $f: \mathbf{R} \rightarrow \mathbf{R}$ be defined by

$$f(x) = \begin{cases} x^2 \sin \frac{1}{x} & x \neq 0, \\ 0 & x = 0. \end{cases}$$

Show that f is differentiable at 0 but f' is not continuous at 0.

(b) Let $f: \mathbf{R}^2 \rightarrow \mathbf{R}$ be defined by

$$f(x, y) = \begin{cases} (x^2 + y^2) \sin \frac{1}{\sqrt{x^2 + y^2}} & (x, y) \neq 0, \\ 0 & (x, y) = 0. \end{cases}$$

Show that f is differentiable at $(0, 0)$ but $D_i f$ is not continuous at $(0, 0)$.

2-33. Show that the continuity of $D_1 f^j$ at a may be eliminated from the hypothesis of Theorem 2-8.

2-34. A function $f: \mathbf{R}^n \rightarrow \mathbf{R}$ is **homogeneous** of degree m if $f(tx) = t^m f(x)$ for all x . If f is also differentiable, show that

$$\sum_{i=1}^n x^i D_i f(x) = m f(x).$$

Hint: If $g(t) = f(tx)$, find $g'(1)$.

2-35. If $f: \mathbf{R}^n \rightarrow \mathbf{R}$ is differentiable and $f(0) = 0$, prove that there exist $g_i: \mathbf{R}^n \rightarrow \mathbf{R}$ such that

$$f(x) = \sum_{i=1}^n x^i g_i(x).$$

Hint: If $h_x(t) = f(tx)$, then $f(x) = \int_0^1 h_x'(t) dt$.

INVERSE FUNCTIONS

Suppose that $f: \mathbf{R} \rightarrow \mathbf{R}$ is continuously differentiable in an open set containing a and $f'(a) \neq 0$. If $f'(a) > 0$, there is an open interval V containing a such that $f'(x) > 0$ for $x \in V$, and a similar statement holds if $f'(a) < 0$. Thus f is increasing (or decreasing) on V , and is therefore 1-1 with an inverse function f^{-1} defined on some open interval W containing $f(a)$. Moreover it is not hard to show that f^{-1} is differentiable, and for $y \in W$ that

$$(f^{-1})'(y) = \frac{1}{f'(f^{-1}(y))}.$$

An analogous discussion in higher dimensions is much more involved, but the result (Theorem 2-11) is very important. We begin with a simple lemma.

2-10 Lemma. Let $A \subset \mathbf{R}^n$ be a rectangle and let $f: A \rightarrow \mathbf{R}^n$ be continuously differentiable. If there is a number M such that $|D_j f^i(x)| \leq M$ for all x in the interior of A , then

$$|f(x) - f(y)| \leq n^2 M |x - y|$$

for all $x, y \in A$.

Proof. We have

$$\begin{aligned} f^i(y) - f^i(x) &= \sum_{j=1}^n [f^i(y^1, \dots, y^j, x^{j+1}, \dots, x^n) \\ &\quad - f^i(y^1, \dots, y^{j-1}, x^j, \dots, x^n)]. \end{aligned}$$

Applying the mean-value theorem we obtain

$$\begin{aligned} f^i(y^1, \dots, y^j, x^{j+1}, \dots, x^n) - f^i(y^1, \dots, y^{j-1}, x^j, \dots, x^n) \\ = (y^j - x^j) \cdot D_j f^i(z_{ij}) \end{aligned}$$

for some z_{ij} . The expression on the right has absolute value less than or equal to $M \cdot |y^j - x^j|$. Thus

$$|f^i(y) - f^i(x)| \leq \sum_{j=1}^n |y^j - x^j| \cdot M \leq nM |y - x|$$

since each $|y^j - x^j| \leq |y - x|$. Finally

$$|f(y) - f(x)| \leq \sum_{i=1}^n |f^i(y) - f^i(x)| \leq n^2 M \cdot |y - x|. \quad \blacksquare$$

2-11 Theorem (Inverse Function Theorem). Suppose that $f: \mathbf{R}^n \rightarrow \mathbf{R}^n$ is continuously differentiable in an open set containing a , and $\det f'(a) \neq 0$. Then there is an open set V containing a and an open set W containing $f(a)$ such that $f: V \rightarrow W$ has a continuous inverse $f^{-1}: W \rightarrow V$ which is differentiable and for all $y \in W$ satisfies

$$(f^{-1})'(y) = [f'(f^{-1}(y))]^{-1}.$$

Proof. Let λ be the linear transformation $Df(a)$. Then λ is non-singular, since $\det f'(a) \neq 0$. Now $D(\lambda^{-1} \circ f)(a) = D(\lambda^{-1})(f(a)) \circ Df(a) = \lambda^{-1} \circ Df(a)$ is the identity linear

transformation. If the theorem is true for $\lambda^{-1} \circ f$, it is clearly true for f . Therefore we may assume at the outset that λ is the identity. Thus whenever $f(a + h) = f(a)$, we have

$$\frac{|f(a + h) - f(a) - \lambda(h)|}{|h|} = \frac{|h|}{|h|} = 1.$$

But

$$\lim_{h \rightarrow 0} \frac{|f(a + h) - f(a) - \lambda(h)|}{|h|} = 0.$$

This means that we cannot have $f(x) = f(a)$ for x arbitrarily close to, but unequal to, a . Therefore there is a closed rectangle U containing a in its interior such that

1. $f(x) \neq f(a)$ if $x \in U$ and $x \neq a$.

Since f is continuously differentiable in an open set containing a , we can also assume that

2. $\det f'(x) \neq 0$ for $x \in U$.
3. $|D_j f^i(x) - D_j f^i(a)| < 1/2n^2$ for all i, j , and $x \in U$.

Note that (3) and Lemma 2-10 applied to $g(x) = f(x) - x$ imply for $x_1, x_2 \in U$ that

$$|f(x_1) - x_1 - (f(x_2) - x_2)| \leq \frac{1}{2}|x_1 - x_2|.$$

Since

$$\begin{aligned} |x_1 - x_2| - |f(x_1) - f(x_2)| &\leq |f(x_1) - x_1 - (f(x_2) - x_2)| \\ &\leq \frac{1}{2}|x_1 - x_2|, \end{aligned}$$

we obtain

4. $|x_1 - x_2| \leq 2|f(x_1) - f(x_2)|$ for $x_1, x_2 \in U$.

Now $f(\text{boundary } U)$ is a compact set which, by (1), does not contain $f(a)$ (Figure 2-3). Therefore there is a number $d > 0$ such that $|f(a) - f(x)| \geq d$ for $x \in \text{boundary } U$. Let $W = \{y: |y - f(a)| < d/2\}$. If $y \in W$ and $x \in \text{boundary } U$, then

5. $|y - f(a)| < |y - f(x)|$.

We will show that for any $y \in W$ there is a unique x in interior U such that $f(x) = y$. To prove this consider the

FIGURE 2-3

function $g: U \rightarrow \mathbf{R}$ defined by

$$g(x) = |y - f(x)|^2 = \sum_{i=1}^n (y^i - f^i(x))^2.$$

This function is continuous and therefore has a minimum on U . If $x \in \text{boundary } U$, then, by (5), we have $g(a) < g(x)$. Therefore the minimum of g does *not* occur on the boundary of U . By Theorem 2-6 there is a point $x \in \text{interior } U$ such that $D_j g(x) = 0$ for all j , that is

$$\sum_{i=1}^n 2(y^i - f^i(x)) \cdot D_j f^i(x) = 0 \quad \text{for all } j.$$

By (2) the matrix $(D_j f^i(x))$ has non-zero determinant. Therefore we must have $y^i - f^i(x) = 0$ for all i , that is $y = f(x)$. This proves the existence of x . Uniqueness follows immediately from (4).

If $V = (\text{interior } U) \cap f^{-1}(W)$, we have shown that the function $f: V \rightarrow W$ has an inverse $f^{-1}: W \rightarrow V$. We can rewrite (4) as

$$6. |f^{-1}(y_1) - f^{-1}(y_2)| \leq 2|y_1 - y_2| \quad \text{for } y_1, y_2 \in W.$$

This shows that f^{-1} is continuous.

Only the proof that f^{-1} is differentiable remains. Let $\mu = Df(x)$. We will show that f^{-1} is differentiable at $y = f(x)$ with derivative μ^{-1} . As in the proof of Theorem 2-2, for $x_1 \in V$, we have

$$f(x_1) = f(x) + \mu(x_1 - x) + \varphi(x_1 - x),$$

where

$$\lim_{x_1 \rightarrow x} \frac{|\varphi(x_1 - x)|}{|x_1 - x|} = 0.$$

Therefore

$$\mu^{-1}(f(x_1) - f(x)) = x_1 - x + \mu^{-1}(\varphi(x_1 - x)).$$

Since every $y_1 \in W$ is of the form $f(x_1)$ for some $x_1 \in V$, this can be written

$$f^{-1}(y_1) = f^{-1}(y) + \mu^{-1}(y_1 - y) - \mu^{-1}(\varphi(f^{-1}(y_1) - f^{-1}(y))),$$

and it therefore suffices to show that

$$\lim_{y_1 \rightarrow y} \frac{|\mu^{-1}(\varphi(f^{-1}(y_1) - f^{-1}(y)))|}{|y_1 - y|} = 0.$$

Therefore (Problem 1-10) it suffices to show that

$$\lim_{y_1 \rightarrow y} \frac{|\varphi(f^{-1}(y_1) - f^{-1}(y))|}{|y_1 - y|} = 0.$$

Now

$$\begin{aligned} \frac{|\varphi(f^{-1}(y_1) - f^{-1}(y))|}{|y_1 - y|} &= \frac{|\varphi(f^{-1}(y_1) - f^{-1}(y))|}{|f^{-1}(y_1) - f^{-1}(y)|} \cdot \frac{|f^{-1}(y_1) - f^{-1}(y)|}{|y_1 - y|}. \end{aligned}$$

Since f^{-1} is continuous, $f^{-1}(y_1) \rightarrow f^{-1}(y)$ as $y_1 \rightarrow y$. Therefore the first factor approaches 0. Since, by (6), the second factor is less than 2, the product also approaches 0. ■

It should be noted that an inverse function f^{-1} may exist even if $\det f'(a) = 0$. For example, if $f: \mathbf{R} \rightarrow \mathbf{R}$ is defined by $f(x) = x^3$, then $f'(0) = 0$ but f has the inverse function $f^{-1}(x) = \sqrt[3]{x}$. One thing is certain however: if $\det f'(a) = 0$, then f^{-1} cannot be differentiable at $f(a)$. To prove this note that $f \circ f^{-1}(x) = x$. If f^{-1} were differentiable at $f(a)$, the chain rule would give $f'(a) \cdot (f^{-1})'(f(a)) = I$, and consequently $\det f'(a) \cdot \det(f^{-1})'(f(a)) = 1$, contradicting $\det f'(a) = 0$.

Problems. 2-36.* Let $A \subset \mathbf{R}^n$ be an open set and $f: A \rightarrow \mathbf{R}^n$ a continuously differentiable 1-1 function such that $\det f'(x) \neq 0$ for all x . Show that $f(A)$ is an open set and $f^{-1}: f(A) \rightarrow A$ is differentiable. Show also that $f(B)$ is open for any open set $B \subset A$.

2-37. (a) Let $f: \mathbf{R}^2 \rightarrow \mathbf{R}$ be a continuously differentiable function. Show that f is *not* 1-1. *Hint:* If, for example, $D_1 f(x, y) \neq 0$ for all (x, y) in some open set A , consider $g: A \rightarrow \mathbf{R}^2$ defined by $g(x, y) = (f(x, y), y)$.

(b) Generalize this result to the case of a continuously differentiable function $f: \mathbf{R}^n \rightarrow \mathbf{R}^m$ with $m < n$.

2-38. (a) If $f: \mathbf{R} \rightarrow \mathbf{R}$ satisfies $f'(a) \neq 0$ for all $a \in \mathbf{R}$, show that f is 1-1 (on all of \mathbf{R}).

(b) Define $f: \mathbf{R}^2 \rightarrow \mathbf{R}^2$ by $f(x,y) = (e^x \cos y, e^x \sin y)$. Show that $\det f'(x,y) \neq 0$ for all (x,y) but f is not 1-1.

2-39. Use the function $f: \mathbf{R} \rightarrow \mathbf{R}$ defined by

$$f(x) = \begin{cases} \frac{x}{2} + x^2 \sin \frac{1}{x} & x \neq 0, \\ 0 & x = 0, \end{cases}$$

to show that continuity of the derivative cannot be eliminated from the hypothesis of Theorem 2-11.

IMPLICIT FUNCTIONS

Consider the function $f: \mathbf{R}^2 \rightarrow \mathbf{R}$ defined by $f(x,y) = x^2 + y^2 - 1$. If we choose (a,b) with $f(a,b) = 0$ and $a \neq 1, -1$, there are (Figure 2-4) open intervals A containing a and B containing b with the following property: if $x \in A$, there is a unique $y \in B$ with $f(x,y) = 0$. We can therefore define

FIGURE 2-4

a function $g: A \rightarrow \mathbf{R}$ by the condition $g(x) \in B$ and $f(x, g(x)) = 0$ (if $b > 0$, as indicated in Figure 2-4, then $g(x) = \sqrt{1 - x^2}$). For the function f we are considering there is another number b_1 such that $f(a, b_1) = 0$. There will also be an interval B_1 containing b_1 such that, when $x \in A$, we have $f(x, g_1(x)) = 0$ for a unique $g_1(x) \in B_1$ (here $g_1(x) = -\sqrt{1 - x^2}$). Both g and g_1 are differentiable. These functions are said to be defined **implicitly** by the equation $f(x, y) = 0$.

If we choose $a = 1$ or -1 it is impossible to find any such function g defined in an open interval containing a . We would like a simple criterion for deciding when, in general, such a function can be found. More generally we may ask the following: If $f: \mathbf{R}^n \times \mathbf{R} \rightarrow \mathbf{R}$ and $f(a^1, \dots, a^n, b) = 0$, when can we find, for each (x^1, \dots, x^n) near (a^1, \dots, a^n) , a unique y near b such that $f(x^1, \dots, x^n, y) = 0$? Even more generally, we can ask about the possibility of solving m equations, depending upon parameters x^1, \dots, x^n , in m unknowns: If

$$f_i: \mathbf{R}^n \times \mathbf{R}^m \rightarrow \mathbf{R} \quad i = 1, \dots, m$$

and

$$f_i(a^1, \dots, a^n, b^1, \dots, b^m) = 0 \quad i = 1, \dots, m,$$

when can we find, for each (x^1, \dots, x^n) near (a^1, \dots, a^n) a unique (y^1, \dots, y^m) near (b^1, \dots, b^m) which satisfies $f_i(x^1, \dots, x^n, y^1, \dots, y^m) = 0$? The answer is provided by

2-12 Theorem (Implicit Function Theorem). Suppose $f: \mathbf{R}^n \times \mathbf{R}^m \rightarrow \mathbf{R}^m$ is continuously differentiable in an open set containing (a, b) and $f(a, b) = 0$. Let M be the $m \times m$ matrix

$$(D_{n+j}f^i(a, b)) \quad 1 \leq i, j \leq m.$$

If $\det M \neq 0$, there is an open set $A \subset \mathbf{R}^n$ containing a and an open set $B \subset \mathbf{R}^m$ containing b , with the following property: for each $x \in A$ there is a unique $g(x) \in B$ such that $f(x, g(x)) = 0$. The function g is differentiable.

Proof. Define $F: \mathbf{R}^n \times \mathbf{R}^m \rightarrow \mathbf{R}^n \times \mathbf{R}^m$ by $F(x, y) = (x, f(x, y))$. Then $\det F'(a, b) = \det M \neq 0$. By Theorem 2-11 there is an open set $W \subset \mathbf{R}^n \times \mathbf{R}^m$ containing $F(a, b) = (a, 0)$ and an open set in $\mathbf{R}^n \times \mathbf{R}^m$ containing (a, b) , which we may take to be of the form $A \times B$, such that $F: A \times B \rightarrow W$ has a differentiable inverse $h: W \rightarrow A \times B$. Clearly h is of the form $h(x, y) = (x, k(x, y))$ for some differentiable function k (since F is of this form). Let $\pi: \mathbf{R}^n \times \mathbf{R}^m \rightarrow \mathbf{R}^m$ be defined by $\pi(x, y) = y$; then $\pi \circ F = f$. Therefore

$$\begin{aligned} f(x, k(x, y)) &= f \circ h(x, y) = (\pi \circ F) \circ h(x, y) \\ &= \pi \circ (F \circ h)(x, y) = \pi(x, y) = y. \end{aligned}$$

Thus $f(x, k(x, 0)) = 0$; in other words we can define $g(x) = k(x, 0)$. ■

Since the function g is known to be differentiable, it is easy to find its derivative. In fact, since $f^i(x, g(x)) = 0$, taking D_j of both sides gives

$$0 = D_j f^i(x, g(x)) + \sum_{\alpha=1}^m D_{n+\alpha} f^i(x, g(x)) \cdot D_j g^\alpha(x)$$

$$i, j = 1, \dots, m.$$

Since $\det M \neq 0$, these equations can be solved for $D_j g^\alpha(x)$. The answer will depend on the various $D_j f^i(x, g(x))$, and therefore on $g(x)$. This is unavoidable, since the function g is not unique. Reconsidering the function $f: \mathbf{R}^2 \rightarrow \mathbf{R}$ defined by $f(x, y) = x^2 + y^2 - 1$, we note that two possible functions satisfying $f(x, g(x)) = 0$ are $g(x) = \sqrt{1 - x^2}$ and $g(x) = -\sqrt{1 - x^2}$. Differentiating $f(x, g(x)) = 0$ gives

$$D_1 f(x, g(x)) + D_2 f(x, g(x)) \cdot g'(x) = 0,$$

or

$$\begin{aligned} 2x + 2g(x) \cdot g'(x) &= 0, \\ g'(x) &= -x/g(x), \end{aligned}$$

which is indeed the case for either $g(x) = \sqrt{1 - x^2}$ or $g(x) = -\sqrt{1 - x^2}$.

A generalization of the argument for Theorem 2-12 can be given, which will be important in Chapter 5.

2-13 Theorem. Let $f: \mathbf{R}^n \rightarrow \mathbf{R}^p$ be continuously differentiable in an open set containing a , where $p \leq n$. If $f(a) = 0$ and the $p \times n$ matrix $(D_j f^i(a))$ has rank p , then there is an open set $A \subset \mathbf{R}^n$ containing a and a differentiable function $h: A \rightarrow \mathbf{R}^n$ with differentiable inverse such that

$$f \circ h(x^1, \dots, x^n) = (x^{n-p+1}, \dots, x^n).$$

Proof. We can consider f as a function $f: \mathbf{R}^{n-p} \times \mathbf{R}^p \rightarrow \mathbf{R}^p$. If $\det M \neq 0$, then M is the $p \times p$ matrix $(D_{n-p+j} f^i(a))$, $1 \leq i, j \leq p$, then we are precisely in the situation considered in the proof of Theorem 2-12, and as we showed in that proof, there is h such that $f \circ h(x^1, \dots, x^n) = (x^{n-p+1}, \dots, x^n)$.

In general, since $(D_j f^i(a))$ has rank p , there will be $j_1 < \dots < j_p$ such that the matrix $(D_j f^i(a))$ $1 \leq i \leq p$, $j = j_1, \dots, j_p$ has non-zero determinant. If $g: \mathbf{R}^n \rightarrow \mathbf{R}^n$ permutes the x^j so that $g(x^1, \dots, x^n) = (\dots, x^{j_1}, \dots, x^{j_p})$, then $f \circ g$ is a function of the type already considered, so $((f \circ g) \circ k)(x^1, \dots, x^n) = (x^{n-p+1}, \dots, x^n)$ for some k . Let $h = g \circ k$. ■

Problems. 2-40. Use the implicit function theorem to re-do Problem 2-15(c).

2-41. Let $f: \mathbf{R} \times \mathbf{R} \rightarrow \mathbf{R}$ be differentiable. For each $x \in \mathbf{R}$ define $g_x: \mathbf{R} \rightarrow \mathbf{R}$ by $g_x(y) = f(x, y)$. Suppose that for each x there is a unique y with $g'_x(y) = 0$; let $c(x)$ be this y .

(a) If $D_{2,2}f(x, y) \neq 0$ for all (x, y) , show that c is differentiable and

$$c'(x) = - \frac{D_{2,1}f(x, c(x))}{D_{2,2}f(x, c(x))}.$$

Hint: $g'_x(y) = 0$ can be written $D_2f(x, y) = 0$.

(b) Show that if $c'(x) = 0$, then for some y we have

$$\begin{aligned} D_{2,1}f(x, y) &= 0, \\ D_{2,2}f(x, y) &= 0. \end{aligned}$$

(c) Let $f(x, y) = x(y \log y - y) - y \log x$. Find

$$\max_{\frac{1}{2} \leq x \leq 2} \left(\min_{\frac{1}{2} \leq y \leq 1} f(x, y) \right).$$

NOTATION

This section is a brief and not entirely unprejudiced discussion of classical notation connected with partial derivatives.

The partial derivative $D_1f(x,y,z)$ is denoted, among devotees of classical notation, by

$$\frac{\partial f(x,y,z)}{\partial x} \quad \text{or} \quad \frac{\partial f}{\partial x} \quad \text{or} \quad \frac{\partial f}{\partial x}(x,y,z) \quad \text{or} \quad \frac{\partial}{\partial x} f(x,y,z)$$

or any other convenient similar symbol. This notation forces one to write

$$\frac{\partial f}{\partial u}(u,v,w)$$

for $D_1f(u,v,w)$, although the symbol

$$\left. \frac{\partial f(x,y,z)}{\partial x} \right|_{(x,y,z)=(u,v,w)} \quad \text{or} \quad \frac{\partial f(x,y,z)}{\partial x}(u,v,w)$$

or something similar may be used (and must be used for an expression like $D_1f(7,3,2)$). Similar notation is used for D_2f and D_3f . Higher-order derivatives are denoted by symbols like

$$D_2D_1f(x,y,z) = \frac{\partial^2 f(x,y,z)}{\partial y \partial x}.$$

When $f: \mathbf{R} \rightarrow \mathbf{R}$, the symbol ∂ automatically reverts to d ; thus

$$\frac{d \sin x}{dx}, \quad \text{not} \quad \frac{\partial \sin x}{\partial x}.$$

The mere statement of Theorem 2-2 in classical notation requires the introduction of irrelevant letters. The usual evaluation for $D_1(f \circ (g,h))$ runs as follows:

If $f(u,v)$ is a function and $u = g(x,y)$ and $v = h(x,y)$, then

$$\frac{\partial f(g(x,y), h(x,y))}{\partial x} = \frac{\partial f(u,v)}{\partial u} \frac{\partial u}{\partial x} + \frac{\partial f(u,v)}{\partial v} \frac{\partial v}{\partial x}.$$

[The symbol $\partial u / \partial x$ means $\partial / \partial x g(x,y)$ and $\partial / \partial u f(u,v)$ means

$D_1f(u,v) = D_1f(g(x,y), h(x,y)).]$ This equation is often written simply

$$\frac{\partial f}{\partial x} = \frac{\partial f}{\partial u} \frac{\partial u}{\partial x} + \frac{\partial f}{\partial v} \frac{\partial v}{\partial x}.$$

Note that f means something different on the two sides of the equation!

The notation df/dx , always a little too tempting, has inspired many (usually meaningless) definitions of dx and df separately, the sole purpose of which is to make the equation

$$df = \frac{df}{dx} \cdot dx$$

work out. If $f: \mathbf{R}^2 \rightarrow \mathbf{R}$ then df is *defined*, classically, as

$$df = \frac{\partial f}{\partial x} dx + \frac{\partial f}{\partial y} dy$$

(whatever dx and dy mean).

Chapter 4 contains rigorous definitions which enable us to prove the above equations as theorems. It is a touchy question whether or not these modern definitions represent a real improvement over classical formalism; this the reader must decide for himself.

3

Integration

BASIC DEFINITIONS

The definition of the integral of a function $f: A \rightarrow \mathbf{R}$, where $A \subset \mathbf{R}^n$ is a closed rectangle, is so similar to that of the ordinary integral that a rapid treatment will be given.

Recall that a partition P of a closed interval $[a, b]$ is a sequence t_0, \dots, t_k , where $a = t_0 \leq t_1 \leq \dots \leq t_k = b$. The partition P divides the interval $[a, b]$ into k subintervals $[t_{i-1}, t_i]$. A **partition** of a rectangle $[a_1, b_1] \times \dots \times [a_n, b_n]$ is a collection $P = (P_1, \dots, P_n)$, where each P_i is a partition of the interval $[a_i, b_i]$. Suppose, for example, that $P_1 = t_0, \dots, t_k$ is a partition of $[a_1, b_1]$ and $P_2 = s_0, \dots, s_l$ is a partition of $[a_2, b_2]$. Then the partition $P = (P_1, P_2)$ of $[a_1, b_1] \times [a_2, b_2]$ divides the closed rectangle $[a_1, b_1] \times [a_2, b_2]$ into $k \cdot l$ subrectangles, a typical one being $[t_{i-1}, t_i] \times [s_{j-1}, s_j]$. In general, if P_i divides $[a_i, b_i]$ into N_i subintervals, then $P = (P_1, \dots, P_n)$ divides $[a_1, b_1] \times \dots \times [a_n, b_n]$ into $N = N_1 \cdot \dots \cdot N_n$ subrectangles. These subrectangles will be called **subrectangles of the partition P** .

Suppose now that A is a rectangle, $f: A \rightarrow \mathbf{R}$ is a bounded

function, and P is a partition of A . For each subrectangle S of the partition let

$$m_S(f) = \inf\{f(x): x \in S\},$$

$$M_S(f) = \sup\{f(x): x \in S\},$$

and let $v(S)$ be the volume of S [the **volume** of a rectangle $[a_1, b_1] \times \cdots \times [a_n, b_n]$, and also of $(a_1, b_1) \times \cdots \times (a_n, b_n)$, is defined as $(b_1 - a_1) \cdot \cdots \cdot (b_n - a_n)$]. The **lower** and **upper sums** of f for P are defined by

$$L(f, P) = \sum_S m_S(f) \cdot v(S) \quad \text{and} \quad U(f, P) = \sum_S M_S(f) \cdot v(S).$$

Clearly $L(f, P) \leq U(f, P)$, and an even stronger assertion (3-2) is true.

3-1 Lemma. *Suppose the partition P' refines P (that is, each subrectangle of P' is contained in a subrectangle of P). Then*

$$L(f, P) \leq L(f, P') \quad \text{and} \quad U(f, P') \leq U(f, P).$$

Proof. Each subrectangle S of P is divided into several subrectangles S_1, \dots, S_α of P' , so $v(S) = v(S_1) + \cdots + v(S_\alpha)$. Now $m_S(f) \leq m_{S_i}(f)$, since the values $f(x)$ for $x \in S$ include all values $f(x)$ for $x \in S_i$ (and possibly smaller ones). Thus

$$\begin{aligned} m_S(f) \cdot v(S) &= m_S(f) \cdot v(S_1) + \cdots + m_S(f) \cdot v(S_\alpha) \\ &\leq m_{S_1}(f) \cdot v(S_1) + \cdots + m_{S_\alpha}(f) \cdot v(S_\alpha). \end{aligned}$$

The sum, for all S , of the terms on the left side is $L(f, P)$, while the sum of all the terms on the right side is $L(f, P')$. Hence $L(f, P) \leq L(f, P')$. The proof for upper sums is similar. ■

3-2 Corollary. *If P and P' are any two partitions, then $L(f, P') \leq U(f, P)$.*

Proof. Let P'' be a partition which refines both P and P' . (For example, let $P'' = (P'_1, \dots, P'_n)$, where P'_i is a par-

tion of $[a_i, b_i]$ which refines both P_i and P'_i .) Then

$$L(f, P') \leq L(f, P'') \leq U(f, P'') \leq U(f, P). \quad \blacksquare$$

It follows from Corollary 3-2 that the least upper bound of all lower sums for f is less than or equal to the greatest lower bound of all upper sums for f . A function $f: A \rightarrow \mathbf{R}$ is called **integrable** on the rectangle A if f is bounded and $\sup\{L(f, P)\} = \inf\{U(f, P)\}$. This common number is then denoted $\int_A f$, and called the **integral** of f over A . Often, the notation $\int_A f(x^1, \dots, x^n) dx^1 \cdots dx^n$ is used. If $f: [a, b] \rightarrow \mathbf{R}$, where $a \leq b$, then $\int_a^b f = \int_{[a, b]} f$. A simple but useful criterion for integrability is provided by

3-3 Theorem. *A bounded function $f: A \rightarrow \mathbf{R}$ is integrable if and only if for every $\epsilon > 0$ there is a partition P of A such that $U(f, P) - L(f, P) < \epsilon$.*

Proof. If this condition holds, it is clear that $\sup\{L(f, P)\} = \inf\{U(f, P)\}$ and f is integrable. On the other hand, if f is integrable, so that $\sup\{L(f, P)\} = \inf\{U(f, P)\}$, then for any $\epsilon > 0$ there are partitions P and P' with $U(f, P) - L(f, P') < \epsilon$. If P'' refines both P and P' , it follows from Lemma 3-1 that $U(f, P'') - L(f, P'') \leq U(f, P) - L(f, P') < \epsilon$. \blacksquare

In the following sections we will characterize the integrable functions and discover a method of computing integrals. For the present we consider two functions, one integrable and one not.

1. Let $f: A \rightarrow \mathbf{R}$ be a constant function, $f(x) = c$. Then for any partition P and subrectangle S we have $m_S(f) = M_S(f) = c$, so that $L(f, P) = U(f, P) = \sum_{sc} c \cdot v(S) = c \cdot v(A)$. Hence $\int_A f = c \cdot v(A)$.

2. Let $f: [0, 1] \times [0, 1] \rightarrow \mathbf{R}$ be defined by

$$f(x, y) = \begin{cases} 0 & \text{if } x \text{ is rational,} \\ 1 & \text{if } x \text{ is irrational.} \end{cases}$$

If P is a partition, then every subrectangle S will contain points (x, y) with x rational, and also points (x, y) with x

irrational. Hence $m_S(f) = 0$ and $M_S(f) = 1$, so

$$L(f, P) = \sum_S 0 \cdot v(S) = 0$$

and

$$U(f, P) = \sum_S 1 \cdot v(S) = v([0, 1] \times [0, 1]) = 1.$$

Therefore f is not integrable.

Problems. 3-1. Let $f: [0, 1] \times [0, 1] \rightarrow \mathbf{R}$ be defined by

$$f(x, y) = \begin{cases} 0 & \text{if } 0 \leq x < \frac{1}{2}, \\ 1 & \text{if } \frac{1}{2} \leq x \leq 1. \end{cases}$$

Show that f is integrable and $\int_{[0, 1] \times [0, 1]} f = \frac{1}{2}$.

3-2. Let $f: A \rightarrow \mathbf{R}$ be integrable and let $g = f$ except at finitely many points. Show that g is integrable and $\int_A f = \int_A g$.

3-3. Let $f, g: A \rightarrow \mathbf{R}$ be integrable.

(a) For any partition P of A and subrectangle S , show that

$$m_S(f) + m_S(g) \leq m_S(f + g) \quad \text{and} \quad M_S(f + g) \leq M_S(f) + M_S(g)$$

and therefore

$$L(f, P) + L(g, P) \leq L(f + g, P) \quad \text{and} \quad U(f + g, P) \leq U(f, P) + U(g, P).$$

(b) Show that $f + g$ is integrable and $\int_A f + g = \int_A f + \int_A g$.

(c) For any constant c , show that $\int_A cf = c \int_A f$.

3-4. Let $f: A \rightarrow \mathbf{R}$ and let P be a partition of A . Show that f is integrable if and only if for each subrectangle S the function $f|_S$, which consists of f restricted to S , is integrable, and that in this case $\int_A f = \sum_S \int_S f|_S$.

3-5. Let $f, g: A \rightarrow \mathbf{R}$ be integrable and suppose $f \leq g$. Show that $\int_A f \leq \int_A g$.

3-6. If $f: A \rightarrow \mathbf{R}$ is integrable, show that $|f|$ is integrable and $|\int_A f| \leq \int_A |f|$.

3-7. Let $f: [0, 1] \times [0, 1] \rightarrow \mathbf{R}$ be defined by

$$f(x, y) = \begin{cases} 0 & x \text{ irrational,} \\ 0 & x \text{ rational, } y \text{ irrational,} \\ 1/q & x \text{ rational, } y = p/q \text{ in lowest terms.} \end{cases}$$

Show that f is integrable and $\int_{[0, 1] \times [0, 1]} f = 0$.

MEASURE ZERO AND CONTENT ZERO

A subset A of \mathbf{R}^n has (n -dimensional) **measure 0** if for every $\varepsilon > 0$ there is a cover $\{U_1, U_2, U_3, \dots\}$ of A by closed rectangles such that $\sum_{i=1}^{\infty} v(U_i) < \varepsilon$. It is obvious (but nevertheless useful to remember) that if A has measure 0 and $B \subset A$, then B has measure 0. The reader may verify that open rectangles may be used instead of closed rectangles in the definition of measure 0.

A set with only finitely many points clearly has measure 0. If A has infinitely many points which can be arranged in a sequence a_1, a_2, a_3, \dots , then A also has measure 0, for if $\varepsilon > 0$, we can choose U_i to be a closed rectangle containing a_i with $v(U_i) < \varepsilon/2^i$. Then $\sum_{i=1}^{\infty} v(U_i) < \sum_{i=1}^{\infty} \varepsilon/2^i = \varepsilon$.

The set of all rational numbers between 0 and 1 is an important and rather surprising example of an infinite set whose members can be arranged in such a sequence. To see that this is so, list the fractions in the following array in the order indicated by the arrows (deleting repetitions and numbers greater than 1):

An important generalization of this idea can be given.

3-4 Theorem. *If $A = A_1 \cup A_2 \cup A_3 \cup \dots$ and each A_i has measure 0, then A has measure 0.*

Proof. Let $\varepsilon > 0$. Since A_i has measure 0, there is a cover $\{U_{i,1}, U_{i,2}, U_{i,3}, \dots\}$ of A_i by closed rectangles such that $\sum_{j=1}^{\infty} v(U_{i,j}) < \varepsilon/2^i$. Then the collection of all $U_{i,j}$ is a cover

of A . By considering the array

we see that this collection can be arranged in a sequence V_1, V_2, V_3, \dots . Clearly $\sum_{i=1}^{\infty} v(V_i) < \sum_{i=1}^{\infty} \epsilon/2^i = \epsilon$. ■

A subset A of \mathbf{R}^n has (n -dimensional) **content 0** if for every $\epsilon > 0$ there is a *finite* cover $\{U_1, \dots, U_n\}$ of A by closed rectangles such that $\sum_{i=1}^n v(U_i) < \epsilon$. If A has content 0, then A clearly has measure 0. Again, open rectangles could be used instead of closed rectangles in the definition.

3-5 Theorem. *If $a < b$, then $[a, b] \subset \mathbf{R}$ does not have content 0. In fact, if $\{U_1, \dots, U_n\}$ is a finite cover of $[a, b]$ by closed intervals, then $\sum_{i=1}^n v(U_i) \geq b - a$.*

Proof. Clearly we can assume that each $U_i \subset [a, b]$. Let $a = t_0 < t_1 < \dots < t_k = b$ be all endpoints of all U_i . Then each $v(U_i)$ is the sum of certain $t_j - t_{j-1}$. Moreover, each $[t_{j-1}, t_j]$ lies in at least one U_i (namely, any one which contains an interior point of $[t_{j-1}, t_j]$), so $\sum_{i=1}^n v(U_i) \geq \sum_{j=1}^k (t_j - t_{j-1}) = b - a$. ■

If $a < b$, it is also true that $[a, b]$ does not have measure 0. This follows from

3-6 Theorem. *If A is compact and has measure 0, then A has content 0.*

Proof. Let $\epsilon > 0$. Since A has measure 0, there is a cover $\{U_1, U_2, \dots\}$ of A by open rectangles such that $\sum_{i=1}^{\infty} v(U_i)$

$< \varepsilon$. Since A is compact, a finite number U_1, \dots, U_n of the U_i also cover A and surely $\sum_{i=1}^n v(U_i) < \varepsilon$. ■

The conclusion of Theorem 3-6 is false if A is not compact. For example, let A be the set of rational numbers between 0 and 1; then A has measure 0. Suppose, however, that $\{[a_1, b_1], \dots, [a_n, b_n]\}$ covers A . Then A is contained in the closed set $[a_1, b_1] \cup \dots \cup [a_n, b_n]$, and therefore $[0, 1] \subset [a_1, b_1] \cup \dots \cup [a_n, b_n]$. It follows from Theorem 3-5 that $\sum_{i=1}^n (b_i - a_i) \geq 1$ for any such cover, and consequently A does not have content 0.

Problems. 3-8. Prove that $[a_1, b_1] \times \dots \times [a_n, b_n]$ does not have content 0 if $a_i < b_i$ for each i .

3-9. (a) Show that an unbounded set cannot have content 0.

(b) Give an example of a closed set of measure 0 which does not have content 0.

3-10. (a) If C is a set of content 0, show that the boundary of C has content 0.

(b) Give an example of a bounded set C of measure 0 such that the boundary of C does not have measure 0.

3-11. Let A be the set of Problem 1-18. If $\sum_{i=1}^{\infty} (b_i - a_i) < 1$, show that the boundary of A does not have measure 0.

3-12. Let $f: [a, b] \rightarrow \mathbf{R}$ be an increasing function. Show that $\{x: f \text{ is discontinuous at } x\}$ has measure 0. *Hint:* Use Problem 1-30 to show that $\{x: o(f, x) > 1/n\}$ is finite, for each integer n .

3-13.* (a) Show that the collection of all rectangles $[a_1, b_1] \times \dots \times [a_n, b_n]$ with all a_i and b_i rational can be arranged in a sequence.

(b) If $A \subset \mathbf{R}^n$ is any set and \mathcal{O} is an open cover of A , show that there is a sequence U_1, U_2, U_3, \dots of members of \mathcal{O} which also cover A . *Hint:* For each $x \in A$ there is a rectangle $B = [a_1, b_1] \times \dots \times [a_n, b_n]$ with all a_i and b_i rational such that $x \in B \subset U$ for some $U \in \mathcal{O}$.

INTEGRABLE FUNCTIONS

Recall that $o(f, x)$ denotes the oscillation of f at x .

3-7 Lemma. Let A be a closed rectangle and let $f: A \rightarrow \mathbf{R}$ be a bounded function such that $o(f, x) < \varepsilon$ for all $x \in A$. Then there is a partition P of A with $U(f, P) - L(f, P) < \varepsilon \cdot v(A)$.

Proof. For each $x \in A$ there is a closed rectangle U_x , containing x in its interior, such that $M_{U_x}(f) - m_{U_x}(f) < \epsilon$. Since A is compact, a finite number U_{x_1}, \dots, U_{x_n} of the sets U_x cover A . Let P be a partition for A such that each subrectangle S of P is contained in some U_{x_i} . Then $M_S(f) - m_S(f) < \epsilon$ for each subrectangle S of P , so that $U(f, P) - L(f, P) = \sum_S [M_S(f) - m_S(f)] \cdot v(S) < \epsilon \cdot v(A)$. ■

3-8 Theorem. Let A be a closed rectangle and $f: A \rightarrow \mathbf{R}$ a bounded function. Let $B = \{x: f \text{ is not continuous at } x\}$. Then f is integrable if and only if B is a set of measure 0.

Proof. Suppose first that B has measure 0. Let $\epsilon > 0$ and let $B_\epsilon = \{x: o(f, x) \geq \epsilon\}$. Then $B_\epsilon \subset B$, so that B_ϵ has measure 0. Since (Theorem 1-11) B_ϵ is compact, B_ϵ has content 0. Thus there is a finite collection U_1, \dots, U_n of closed rectangles, whose interiors cover B_ϵ , such that $\sum_{i=1}^n v(U_i) < \epsilon$. Let P be a partition of A such that every subrectangle S of P is in one of two groups (see Figure 3-1):

FIGURE 3-1. The shaded rectangles are in \mathcal{S}_1 .

- (1) \mathfrak{S}_1 , which consists of subrectangles S , such that $S \subset U_i$ for some i .
- (2) \mathfrak{S}_2 , which consists of subrectangles S with $S \cap B_\varepsilon = \emptyset$.

Let $|f(x)| < M$ for $x \in A$. Then $M_S(f) - m_S(f) < 2M$ for every S . Therefore

$$\sum_{S \in \mathfrak{S}_1} [M_S(f) - m_S(f)] \cdot v(S) < 2M \sum_{i=1}^n v(U_i) < 2M\varepsilon.$$

Now, if $S \in \mathfrak{S}_2$, then $o(f, x) < \varepsilon$ for $x \in S$. Lemma 3-7 implies that there is a refinement P' of P such that

$$\sum_{S' \subset S} [M_{S'}(f) - m_{S'}(f)] \cdot v(S') < \varepsilon \cdot v(S)$$

for $S \in \mathfrak{S}_2$. Then

$$\begin{aligned} U(f, P') - L(f, P') &= \sum_{S' \subset S \in \mathfrak{S}_1} [M_{S'}(f) - m_{S'}(f)] \cdot v(S') \\ &\quad + \sum_{S' \subset S \in \mathfrak{S}_2} [M_{S'}(f) - m_{S'}(f)] \cdot v(S') \\ &< 2M\varepsilon + \sum_{S \in \mathfrak{S}_2} \varepsilon \cdot v(S) \\ &\leq 2M\varepsilon + \varepsilon \cdot v(A). \end{aligned}$$

Since M and $v(A)$ are fixed, this shows that we can find a partition P' with $U(f, P') - L(f, P')$ as small as desired. Thus f is integrable.

Suppose, conversely, that f is integrable. Since $B = B_1 \cup B_{\frac{1}{2}} \cup B_{\frac{1}{3}} \cup \cdots$, it suffices (Theorem 3-4) to prove that each $B_{1/n}$ has measure 0. In fact we will show that each $B_{1/n}$ has content 0 (since $B_{1/n}$ is compact, this is actually equivalent).

If $\varepsilon > 0$, let P be a partition of A such that $U(f, P) - L(f, P) < \varepsilon/n$. Let \mathfrak{S} be the collection of subrectangles S of P which intersect $B_{1/n}$. Then \mathfrak{S} is a cover of $B_{1/n}$. Now if

$S \in \mathfrak{S}$, then $M_S(f) - m_S(f) \geq 1/n$. Thus

$$\begin{aligned} \frac{1}{n} \cdot \sum_{S \in \mathfrak{S}} v(S) &\leq \sum_{S \in \mathfrak{S}} [M_S(f) - m_S(f)] \cdot v(S) \\ &\leq \sum_S [M_S(f) - m_S(f)] \cdot v(S) \\ &< \frac{\varepsilon}{n}, \end{aligned}$$

and consequently $\sum_{S \in \mathfrak{S}} v(S) < \varepsilon$. ■

We have thus far dealt only with the integrals of functions over rectangles. Integrals over other sets are easily reduced to this type. If $C \subset \mathbf{R}^n$, the **characteristic function** χ_C of C is defined by

$$\chi_C(x) = \begin{cases} 0 & x \notin C, \\ 1 & x \in C. \end{cases}$$

If $C \subset A$ for some closed rectangle A and $f: A \rightarrow \mathbf{R}$ is bounded, then $\int_C f$ is defined as $\int_A f \cdot \chi_C$, provided $f \cdot \chi_C$ is integrable. This certainly occurs (Problem 3-14) if f and χ_C are integrable.

3-9 Theorem. *The function $\chi_C: A \rightarrow \mathbf{R}$ is integrable if and only if the boundary of C has measure 0 (and hence content 0).*

Proof. If x is in the interior of C , then there is an open rectangle U with $x \in U \subset C$. Thus $\chi_C = 1$ on U and χ_C is clearly continuous at x . Similarly, if x is in the exterior of C , there is an open rectangle U with $x \in U \subset \mathbf{R}^n - C$. Hence $\chi_C = 0$ on U and χ_C is continuous at x . Finally, if x is in the boundary of C , then for every open rectangle U containing x , there is $y_1 \in U \cap C$, so that $\chi_C(y_1) = 1$ and there is $y_2 \in U \cap (\mathbf{R}^n - C)$, so that $\chi_C(y_2) = 0$. Hence χ_C is not continuous at x . Thus $\{x: \chi_C \text{ is not continuous at } x\} = \text{boundary } C$, and the result follows from Theorem 3-8. ■

A bounded set C whose boundary has measure 0 is called **Jordan-measurable**. The integral $\int_C 1$ is called the (n -dimensional) **content** of C , or the (n -dimensional) **volume** of C . Naturally one-dimensional volume is often called **length**, and two-dimensional volume, **area**.

Problem 3-11 shows that even an open set C may not be Jordan-measurable, so that $\int_C f$ is not necessarily defined even if C is open and f is continuous. This unhappy state of affairs will be rectified soon.

Problems. 3-14. Show that if $f, g: A \rightarrow \mathbf{R}$ are integrable, so is $f \cdot g$.

3-15. Show that if C has content 0, then $C \subset A$ for some closed rectangle A and C is Jordan-measurable and $\int_A \chi_C = 0$.

3-16. Give an example of a bounded set C of measure 0 such that $\int_A \chi_C$ does not exist.

3-17. If C is a bounded set of measure 0 and $\int_A \chi_C$ exists, show that $\int_A \chi_C = 0$. *Hint:* Show that $L(f, P) = 0$ for all partitions P . Use Problem 3-8.

3-18. If $f: A \rightarrow \mathbf{R}$ is non-negative and $\int_A f = 0$, show that $\{x: f(x) \neq 0\}$ has measure 0. *Hint:* Prove that $\{x: f(x) > 1/n\}$ has content 0.

3-19. Let U be the open set of Problem 3-11. Show that if $f = \chi_U$ except on a set of measure 0, then f is not integrable on $[0, 1]$.

3-20. Show that an increasing function $f: [a, b] \rightarrow \mathbf{R}$ is integrable on $[a, b]$.

3-21. If A is a closed rectangle, show that $C \subset A$ is Jordan-measurable if and only if for every $\varepsilon > 0$ there is a partition P of A such that $\sum_{S \in \mathcal{S}_1} v(S) - \sum_{S \in \mathcal{S}_2} v(S) < \varepsilon$, where \mathcal{S}_1 consists of all subrectangles intersecting C and \mathcal{S}_2 all subrectangles contained in C .

3-22.* If A is a Jordan-measurable set and $\varepsilon > 0$, show that there is a compact Jordan-measurable set $C \subset A$ such that $\int_{A-C} 1 < \varepsilon$.

FUBINI'S THEOREM

The problem of calculating integrals is solved, in some sense, by Theorem 3-10, which reduces the computation of integrals over a closed rectangle in \mathbf{R}^n , $n > 1$, to the computation of integrals over closed intervals in \mathbf{R} . Of sufficient importance to deserve a special designation, this theorem is usually referred to as Fubini's theorem, although it is more or less a

special case of a theorem proved by Fubini long after Theorem 3-10 was known.

The idea behind the theorem is best illustrated (Figure 3-2) for a positive continuous function $f: [a,b] \times [c,d] \rightarrow \mathbf{R}$. Let t_0, \dots, t_n be a partition of $[a,b]$ and divide $[a,b] \times [c,d]$ into n strips by means of the line segments $\{t_i\} \times [c,d]$. If g_x is defined by $g_x(y) = f(x,y)$, then the area of the region under the graph of f and above $\{x\} \times [c,d]$ is

$$\int_c^d g_x = \int_c^d f(x,y)dy.$$

The volume of the region under the graph of f and above $[t_{i-1}, t_i] \times [c,d]$ is therefore approximately equal to $(t_i - t_{i-1}) \cdot \int_c^d f(x,y)dy$, for any $x \in [t_{i-1}, t_i]$. Thus

$$\int_{[a,b] \times [c,d]} f = \sum_{i=1}^n \int_{[t_{i-1}, t_i] \times [c,d]} f$$

is approximately $\sum_{i=1}^n (t_i - t_{i-1}) \cdot \int_c^d f(x_i, y)dy$, with x_i in

FIGURE 3-2

$[t_{i-1}, t_i]$. On the other hand, sums similar to these appear in the definition of $\int_a^b (\int_c^d f(x, y) dy) dx$. Thus, if h is defined by $h(x) = \int_c^d g_x = \int_c^d f(x, y) dy$, it is reasonable to hope that h is integrable on $[a, b]$ and that

$$\int_{[a,b] \times [c,d]} f = \int_a^b h = \int_a^b \left(\int_c^d f(x, y) dy \right) dx.$$

This will indeed turn out to be true when f is continuous, but in the general case difficulties arise. Suppose, for example, that the set of discontinuities of f is $\{x_0\} \times [c, d]$ for some $x_0 \in [a, b]$. Then f is integrable on $[a, b] \times [c, d]$ but $h(x_0) = \int_c^d f(x_0, y) dy$ may not even be defined. The statement of Fubini's theorem therefore looks a little strange, and will be followed by remarks about various special cases where simpler statements are possible.

We will need one bit of terminology. If $f: A \rightarrow \mathbf{R}$ is a bounded function on a closed rectangle, then, whether or not f is integrable, the least upper bound of all lower sums, and the greatest lower bound of all upper sums, both exist. They are called the **lower** and **upper integrals** of f on A , and denoted

$$\mathbf{L} \int_A f \quad \text{and} \quad \mathbf{U} \int_A f,$$

respectively.

3-10 Theorem (Fubini's Theorem). *Let $A \subset \mathbf{R}^n$ and $B \subset \mathbf{R}^m$ be closed rectangles, and let $f: A \times B \rightarrow \mathbf{R}$ be integrable. For $x \in A$ let $g_x: B \rightarrow \mathbf{R}$ be defined by $g_x(y) = f(x, y)$ and let*

$$\begin{aligned} \mathfrak{L}(x) &= \mathbf{L} \int_B g_x = \mathbf{L} \int_B f(x, y) dy, \\ \mathfrak{U}(x) &= \mathbf{U} \int_B g_x = \mathbf{U} \int_B f(x, y) dy. \end{aligned}$$

Then \mathfrak{L} and \mathfrak{U} are integrable on A and

$$\begin{aligned} \int_{A \times B} f &= \int_A \mathfrak{L} = \int_A \left(\mathbf{L} \int_B f(x, y) dy \right) dx, \\ \int_{A \times B} f &= \int_A \mathfrak{U} = \int_A \left(\mathbf{U} \int_B f(x, y) dy \right) dx. \end{aligned}$$

(The integrals on the right side are called **iterated integrals** for f .)

Proof. Let P_A be a partition of A and P_B a partition of B . Together they give a partition P of $A \times B$ for which any subrectangle S is of the form $S_A \times S_B$, where S_A is a subrectangle of the partition P_A , and S_B is a subrectangle of the partition P_B . Thus

$$\begin{aligned} L(f, P) &= \sum_S m_S(f) \cdot v(S) = \sum_{S_A, S_B} m_{S_A \times S_B}(f) \cdot v(S_A \times S_B) \\ &= \sum_{S_A} \left(\sum_{S_B} m_{S_A \times S_B}(f) \cdot v(S_B) \right) \cdot v(S_A). \end{aligned}$$

Now, if $x \in S_A$, then clearly $m_{S_A \times S_B}(f) \leq m_{S_B}(g_x)$. Consequently, for $x \in S_A$ we have

$$\sum_{S_B} m_{S_A \times S_B}(f) \cdot v(S_B) \leq \sum_{S_B} m_{S_B}(g_x) \cdot v(S_B) \leq \mathbf{L} \int_B g_x = \mathfrak{L}(x).$$

Therefore

$$\sum_{S_A} \left(\sum_{S_B} m_{S_A \times S_B}(f) \cdot v(S_B) \right) \cdot v(S_A) \leq L(\mathfrak{L}, P_A).$$

We thus obtain

$$L(f, P) \leq L(\mathfrak{L}, P_A) \leq U(\mathfrak{L}, P_A) \leq U(\mathfrak{U}, P_A) \leq U(f, P),$$

where the proof of the last inequality is entirely analogous to the proof of the first. Since f is integrable, $\sup\{L(f, P)\} = \inf\{U(f, P)\} = \int_{A \times B} f$. Hence

$$\sup\{L(\mathfrak{L}, P_A)\} = \inf\{U(\mathfrak{L}, P_A)\} = \int_{A \times B} f.$$

In other words, \mathfrak{L} is integrable on A and $\int_{A \times B} f = \int_A \mathfrak{L}$. The assertion for \mathfrak{U} follows similarly from the inequalities

$$L(f, P) \leq L(\mathfrak{L}, P_A) \leq L(\mathfrak{U}, P_A) \leq U(\mathfrak{U}, P_A) \leq U(f, P). \quad \blacksquare$$

Remarks. 1. A similar proof shows that

$$\int_{A \times B} f = \int_B \left(\mathbf{L} \int_A f(x, y) dx \right) dy = \int_B \left(\mathbf{U} \int_A f(x, y) dx \right) dy.$$

These integrals are called *iterated integrals* for f in the reverse order from those of the theorem. As several problems show, the possibility of interchanging the orders of iterated integrals has many consequences.

2. In practice it is often the case that each g_x is integrable, so that $\int_{A \times B} f = \int_A (\int_B f(x, y) dy) dx$. This certainly occurs if f is continuous.

3. The worst irregularity commonly encountered is that g_x is not integrable for a finite number of $x \in A$. In this case $\mathcal{L}(x) = \int_B f(x, y) dy$ for all but these finitely many x . Since $\int_A \mathcal{L}$ remains unchanged if \mathcal{L} is redefined at a finite number of points, we can still write $\int_{A \times B} f = \int_A (\int_B f(x, y) dy) dx$, provided that $\int_B f(x, y) dy$ is defined arbitrarily, say as 0, when it does not exist.

4. There are cases when this will not work and Theorem 3-10 must be used as stated. Let $f: [0, 1] \times [0, 1] \rightarrow \mathbf{R}$ be defined by

$$f(x, y) = \begin{cases} 1 & \text{if } x \text{ is irrational,} \\ 1 & \text{if } x \text{ is rational and } y \text{ is irrational,} \\ 1 - 1/q & \text{if } x = p/q \text{ in lowest terms and } y \text{ is} \\ & \text{rational.} \end{cases}$$

Then f is integrable and $\int_{[0, 1] \times [0, 1]} f = 1$. Now $\int_0^1 f(x, y) dy = 1$ if x is irrational, and does not exist if x is rational. Therefore h is not integrable if $h(x) = \int_0^1 f(x, y) dy$ is set equal to 0 when the integral does not exist.

5. If $A = [a_1, b_1] \times \cdots \times [a_n, b_n]$ and $f: A \rightarrow \mathbf{R}$ is sufficiently nice, we can apply Fubini's theorem repeatedly to obtain

$$\int_A f = \int_{a_n}^{b_n} \left(\cdots \left(\int_{a_1}^{b_1} f(x^1, \dots, x^n) dx^1 \right) \cdots \right) dx^n.$$

6. If $C \subset A \times B$, Fubini's theorem can be used to evaluate $\int_C f$, since this is by definition $\int_{A \times B} \chi_C f$. Suppose, for example, that

$$C = [-1, 1] \times [-1, 1] - \{(x, y): |(x, y)| < 1\}.$$

Then

$$\int_C f = \int_{-1}^1 \left(\int_{-1}^1 f(x, y) \cdot \chi_C(x, y) dy \right) dx.$$

Now

$$\chi_C(x,y) = \begin{cases} 1 & \text{if } y > \sqrt{1-x^2} \text{ or } y < -\sqrt{1-x^2}, \\ 0 & \text{otherwise.} \end{cases}$$

Therefore

$$\int_{-1}^1 f(x,y) \cdot \chi_C(x,y) dy = \int_{-1}^{-\sqrt{1-x^2}} f(x,y) dy + \int_{\sqrt{1-x^2}}^1 f(x,y) dy.$$

In general, if $C \subset A \times B$, the main difficulty in deriving expressions for $\int_C f$ will be determining $C \cap (\{x\} \times B)$ for $x \in A$. If $C \cap (A \times \{y\})$ for $y \in B$ is easier to determine, one should use the iterated integral

$$\int_C f = \int_B \left(\int_A f(x,y) \cdot \chi_C(x,y) dx \right) dy.$$

Problems. 3-23. Let $C \subset A \times B$ be a set of content 0. Let $A' \subset A$ be the set of all $x \in A$ such that $\{y \in B: (x,y) \in C\}$ is not of content 0. Show that A' is a set of measure 0. *Hint:* χ_C is integrable and $\int_{A \times B} \chi_C = \int_A \mathfrak{U} = \int_A \mathfrak{L}$, so $\int_A \mathfrak{U} - \mathfrak{L} = 0$.

3-24. Let $C \subset [0,1] \times [0,1]$ be the union of all $\{p/q\} \times [0, 1/q]$, where p/q is a rational number in $[0,1]$ written in lowest terms. Use C to show that the word “measure” in Problem 3-23 cannot be replaced by “content.”

3-25. Use induction on n to show that $[a_1, b_1] \times \cdots \times [a_n, b_n]$ is not a set of measure 0 (or content 0) if $a_i < b_i$ for each i .

3-26. Let $f: [a,b] \rightarrow \mathbf{R}$ be integrable and non-negative and let $A_f = \{(x,y): a \leq x \leq b \text{ and } 0 \leq y \leq f(x)\}$. Show that A_f is Jordan-measurable and has area $\int_a^b f$.

3-27. If $f: [a,b] \times [a,b] \rightarrow \mathbf{R}$ is continuous, show that

$$\int_a^b \int_a^y f(x,y) dx dy = \int_a^b \int_x^b f(x,y) dy dx.$$

Hint: Compute $\int_C f$ in two different ways for a suitable set $C \subset [a,b] \times [a,b]$.

3-28.* Use Fubini's theorem to give an easy proof that $D_{1,2}f = D_{2,1}f$ if these are continuous. *Hint:* If $D_{1,2}f(a) - D_{2,1}f(a) > 0$, there is a rectangle A containing a such that $D_{1,2}f - D_{2,1}f > 0$ on A .

3-29. Use Fubini's theorem to derive an expression for the volume of a set of \mathbf{R}^3 obtained by revolving a Jordan-measurable set in the yz -plane about the z -axis.

3-30. Let C be the set in Problem 1-17. Show that

$$\int_{[0,1]} \left(\int_{[0,1]} \chi_C(x,y) dx \right) dy = \int_{[0,1]} \left(\int_{[0,1]} \chi_C(y,x) dy \right) dx = 0$$

but that $\int_{[0,1] \times [0,1]} \chi_C$ does not exist.

3-31. If $A = [a_1, b_1] \times \cdots \times [a_n, b_n]$ and $f: A \rightarrow \mathbf{R}$ is continuous, define $F: A \rightarrow \mathbf{R}$ by

$$F(x) = \int_{[a_1, x_1] \times \cdots \times [a_n, x_n]} f.$$

What is $D_i F(x)$, for x in the interior of A ?

3-32.* Let $f: [a, b] \times [c, d] \rightarrow \mathbf{R}$ be continuous and suppose $D_2 f$ is continuous. Define $F(y) = \int_a^b f(x, y) dx$. Prove *Leibnitz's rule*: $F'(y) = \int_a^b D_2 f(x, y) dx$. *Hint*: $F(y) = \int_a^b f(x, y) dx = \int_a^b \left(\int_c^y D_2 f(x, y) dy + f(x, c) \right) dx$. (The proof will show that continuity of $D_2 f$ may be replaced by considerably weaker hypotheses.)

3-33. If $f: [a, b] \times [c, d] \rightarrow \mathbf{R}$ is continuous and $D_2 f$ is continuous, define $F(x, y) = \int_a^x f(t, y) dt$.

(a) Find $D_1 F$ and $D_2 F$.

(b) If $G(x) = \int_a^{g(x)} f(t, x) dt$, find $G'(x)$.

3-34.* Let $g_1, g_2: \mathbf{R}^2 \rightarrow \mathbf{R}$ be continuously differentiable and suppose $D_1 g_2 = D_2 g_1$. As in Problem 2-21, let

$$f(x, y) = \int_0^x g_1(t, 0) dt + \int_0^y g_2(x, t) dt.$$

Show that $D_1 f(x, y) = g_1(x, y)$.

3-35.* (a) Let $g: \mathbf{R}^n \rightarrow \mathbf{R}^n$ be a linear transformation of one of the following types:

$$\begin{cases} g(e_i) = e_i & i \neq j \\ g(e_j) = a e_j \end{cases}$$

$$\begin{cases} g(e_i) = e_i & i \neq j \\ g(e_j) = e_j + e_k \end{cases}$$

$$\begin{cases} g(e_k) = e_k & k \neq i, j \\ g(e_i) = e_j \\ g(e_j) = e_i. \end{cases}$$

If U is a rectangle, show that the volume of $g(U)$ is $|\det g| \cdot v(U)$.

(b) Prove that $|\det g| \cdot v(U)$ is the volume of $g(U)$ for any linear transformation $g: \mathbf{R}^n \rightarrow \mathbf{R}^n$. *Hint*: If $\det g \neq 0$, then g is the composition of linear transformations of the type considered in (a).

3-36. (Cavalieri's principle). Let A and B be Jordan-measurable subsets of \mathbf{R}^3 . Let $A_c = \{(x, y): (x, y, c) \in A\}$ and define B_c similarly. Suppose each A_c and B_c are Jordan-measurable and have the same area. Show that A and B have the same volume.

PARTITIONS OF UNITY

In this section we introduce a tool of extreme importance in the theory of integration.

3-11 Theorem. *Let $A \subset \mathbf{R}^n$ and let \mathcal{O} be an open cover of A . Then there is a collection Φ of C^∞ functions φ defined in an open set containing A , with the following properties:*

- (1) *For each $x \in A$ we have $0 \leq \varphi(x) \leq 1$.*
- (2) *For each $x \in A$ there is an open set V containing x such that all but finitely many $\varphi \in \Phi$ are 0 on V .*
- (3) *For each $x \in A$ we have $\sum_{\varphi \in \Phi} \varphi(x) = 1$ (by (2) for each x this sum is finite in some open set containing x).*
- (4) *For each $\varphi \in \Phi$ there is an open set U in \mathcal{O} such that $\varphi = 0$ outside of some closed set contained in U .*

(A collection Φ satisfying (1) to (3) is called a C^∞ **partition of unity** for A . If Φ also satisfies (4), it is said to be **subordinate** to the cover \mathcal{O} . In this chapter we will only use continuity of the functions φ .)

Proof. *Case 1. A is compact.*

Then a finite number U_1, \dots, U_n of open sets in \mathcal{O} cover A . It clearly suffices to construct a partition of unity subordinate to the cover $\{U_1, \dots, U_n\}$. We will first find compact sets $D_i \subset U_i$ whose interiors cover A . The sets D_i are constructed inductively as follows. Suppose that D_1, \dots, D_k have been chosen so that $\{\text{interior } D_1, \dots, \text{interior } D_k, U_{k+1}, \dots, U_n\}$ covers A . Let

$$C_{k+1} = A - (\text{int } D_1 \cup \dots \cup \text{int } D_k \cup U_{k+2} \cup \dots \cup U_n).$$

Then $C_{k+1} \subset U_{k+1}$ is compact. Hence (Problem 1-22) we can find a compact set D_{k+1} such that

$$C_{k+1} \subset \text{interior } D_{k+1} \quad \text{and} \quad D_{k+1} \subset U_{k+1}.$$

Having constructed the sets D_1, \dots, D_n , let ψ_i be a non-negative C^∞ function which is positive on D_i and 0 outside of some closed set contained in U_i (Problem 2-26). Since

$\{D_1, \dots, D_n\}$ covers A , we have $\psi_1(x) + \dots + \psi_n(x) > 0$ for all x in some open set U containing A . On U we can define

$$\varphi_i(x) = \frac{\psi_i(x)}{\psi_1(x) + \dots + \psi_n(x)}.$$

If $f: U \rightarrow [0,1]$ is a C^∞ function which is 1 on A and 0 outside of some closed set in U , then $\Phi = \{f \cdot \varphi_1, \dots, f \cdot \varphi_n\}$ is the desired partition of unity.

Case 2. $A = A_1 \cup A_2 \cup A_3 \cup \dots$, where each A_i is compact and $A_i \subset \text{interior } A_{i+1}$.

For each i let Θ_i consist of all $U \cap (\text{interior } A_{i+1} - A_{i-2})$ for U in \mathcal{O} . Then Θ_i is an open cover of the compact set $B_i = A_i - \text{interior } A_{i-1}$. By case 1 there is a partition of unity Φ_i for B_i , subordinate to Θ_i . For each $x \in A$ the sum

$$\sigma(x) = \sum_{\varphi \in \Phi_i, \text{ all } i} \varphi(x)$$

is a finite sum in some open set containing x , since if $x \in A_i$ we have $\varphi(x) = 0$ for $\varphi \in \Phi_j$ with $j \geq i+2$. For each φ in each Φ_i , define $\varphi'(x) = \varphi(x)/\sigma(x)$. The collection of all φ' is the desired partition of unity.

Case 3. A is open.

Let $A_i =$

$\{x \in A: |x| \leq i \text{ and distance from } x \text{ to boundary } A \geq 1/i\},$

and apply case 2.

Case 4. A is arbitrary.

Let B be the union of all U in \mathcal{O} . By case 3 there is a partition of unity for B ; this is also a partition of unity for A . ■

An important consequence of condition (2) of the theorem should be noted. Let $C \subset A$ be compact. For each $x \in C$ there is an open set V_x containing x such that only finitely many $\varphi \in \Phi$ are not 0 on V_x . Since C is compact, finitely many such V_x cover C . Thus only finitely many $\varphi \in \Phi$ are not 0 on C .

One important application of partitions of unity will illustrate their main role—piecing together results obtained locally.

An open cover \mathcal{O} of an open set $A \subset \mathbf{R}^n$ is **admissible** if each $U \in \mathcal{O}$ is contained in A . If Φ is subordinate to \mathcal{O} , $f: A \rightarrow \mathbf{R}$ is bounded in some open set around each point of A , and $\{x: f \text{ is discontinuous at } x\}$ has measure 0, then each $\int_A \varphi \cdot |f|$ exists. We define f to be **integrable** (in the extended sense) if $\sum_{\varphi \in \Phi} \int_A \varphi \cdot |f|$ converges (the proof of Theorem 3-11 shows that the φ 's may be arranged in a sequence). This implies convergence of $\sum_{\varphi \in \Phi} \left| \int_A \varphi \cdot f \right|$, and hence absolute convergence of $\sum_{\varphi \in \Phi} \int_A \varphi \cdot f$, which we define to be $\int_A f$. These definitions do not depend on \mathcal{O} or Φ (but see Problem 3-38).

3-12 Theorem.

- (1) If Ψ is another partition of unity, subordinate to an admissible cover \mathcal{O}' of A , then $\sum_{\psi \in \Psi} \int_A \psi \cdot |f|$ also converges, and

$$\sum_{\varphi \in \Phi} \int_A \varphi \cdot f = \sum_{\psi \in \Psi} \int_A \psi \cdot f.$$

- (2) If A and f are bounded, then f is integrable in the extended sense.
 (3) If A is Jordan-measurable and f is bounded, then this definition of $\int_A f$ agrees with the old one.

Proof

- (1) Since $\varphi \cdot f = 0$ except on some compact set C , and there are only finitely many ψ which are non-zero on C , we can write

$$\sum_{\varphi \in \Phi} \int_A \varphi \cdot f = \sum_{\varphi \in \Phi} \int_A \sum_{\psi \in \Psi} \psi \cdot \varphi \cdot f = \sum_{\varphi \in \Phi} \sum_{\psi \in \Psi} \int_A \psi \cdot \varphi \cdot f.$$

This result, applied to $|f|$, shows the convergence of $\sum_{\varphi \in \Phi} \sum_{\psi \in \Psi} \int_A \psi \cdot \varphi \cdot |f|$, and hence of $\sum_{\varphi \in \Phi} \sum_{\psi \in \Psi} \left| \int_A \psi \cdot \varphi \cdot f \right|$. This absolute convergence justifies interchanging the order of summation in the above equation; the resulting double sum clearly equals $\sum_{\psi \in \Psi} \int_A \psi \cdot f$. Finally, this result applied to $|f|$ proves convergence of $\sum_{\psi \in \Psi} \int_A \psi \cdot |f|$.

- (2) If A is contained in the closed rectangle B and $|f(x)| \leq M$ for $x \in A$, and $F \subset \Phi$ is finite, then

$$\sum_{\varphi \in F} \int_A \varphi \cdot |f| \leq \sum_{\varphi \in F} M \int_A \varphi = M \int_A \sum_{\varphi \in F} \varphi \leq Mv(B),$$

since $\sum_{\varphi \in F} \varphi \leq 1$ on A .

- (3) If $\varepsilon > 0$ there is (Problem 3-22) a compact Jordan-measurable $C \subset A$ such that $\int_{A-C} 1 < \varepsilon$. There are only finitely many $\varphi \in \Phi$ which are non-zero on C . If $F \subset \Phi$ is any finite collection which includes these, and $\int_A f$ has its old meaning, then

$$\begin{aligned} \left| \int_A f - \sum_{\varphi \in F} \int_A \varphi \cdot f \right| &\leq \int_A \left| f - \sum_{\varphi \in F} \varphi \cdot f \right| \\ &\leq M \int_A \left(1 - \sum_{\varphi \in F} \varphi \right) \\ &= M \int_A \sum_{\varphi \in \Phi - F} \varphi \leq M \int_{A-C} 1 \leq M\varepsilon. \quad \blacksquare \end{aligned}$$

Problems. 3-37. (a) Suppose that $f: (0,1) \rightarrow \mathbf{R}$ is a non-negative continuous function. Show that $\int_{(0,1)} f$ exists if and only if $\lim_{\varepsilon \rightarrow 0} \int_{\varepsilon}^{1-\varepsilon} f$ exists.

(b) Let $A_n = [1 - 1/2^n, 1 - 1/2^{n+1}]$. Suppose that $f: (0,1) \rightarrow \mathbf{R}$ satisfies $\int_{A_n} f = (-1)^n/n$ and $f(x) = 0$ for $x \notin \text{any } A_n$. Show that $\int_{(0,1)} f$ does not exist, but $\lim_{\varepsilon \rightarrow 0} \int_{(\varepsilon, 1-\varepsilon)} f = \log 2$.

- 3-38. Let A_n be a closed set contained in $(n, n+1)$. Suppose that $f: \mathbf{R} \rightarrow \mathbf{R}$ satisfies $\int_{A_n} f = (-1)^n/n$ and $f = 0$ for $x \notin \text{any } A_n$. Find two partitions of unity Φ and Ψ such that $\sum_{\varphi \in \Phi} \int_{\mathbf{R}} \varphi \cdot f$ and $\sum_{\psi \in \Psi} \int_{\mathbf{R}} \psi \cdot f$ converge absolutely to different values.

CHANGE OF VARIABLE

If $g: [a,b] \rightarrow \mathbf{R}$ is continuously differentiable and $f: \mathbf{R} \rightarrow \mathbf{R}$ is continuous, then, as is well known,

$$\int_{g(a)}^{g(b)} f = \int_a^b (f \circ g) \cdot g'.$$

The proof is very simple: if $F' = f$, then $(F \circ g)' = (f \circ g) \cdot g'$; thus the left side is $F(g(b)) - F(g(a))$, while the right side is $F \circ g(b) - F \circ g(a) = F(g(b)) - F(g(a))$.

We leave it to the reader to show that if g is 1-1, then the above formula can be written

$$\int_{g((a,b))} f = \int_{(a,b)} f \circ g \cdot |g'|.$$

(Consider separately the cases where g is increasing and where g is decreasing.) The generalization of this formula to higher dimensions is by no means so trivial.

3-13 Theorem. *Let $A \subset \mathbf{R}^n$ be an open set and $g: A \rightarrow \mathbf{R}^n$ a 1-1, continuously differentiable function such that $\det g'(x) \neq 0$ for all $x \in A$. If $f: g(A) \rightarrow \mathbf{R}$ is integrable, then*

$$\int_{g(A)} f = \int_A (f \circ g) |\det g'|.$$

Proof. We begin with some important reductions.

1. Suppose there is an admissible cover \mathcal{O} for A such that for each $U \in \mathcal{O}$ and any integrable f we have

$$\int_{g(U)} f = \int_U (f \circ g) |\det g'|.$$

Then the theorem is true for all of A . (Since g is automatically 1-1 in an open set around each point, it is not surprising that this is the only part of the proof using the fact that g is 1-1 on all of A .)

Proof of (1). The collection of all $g(U)$ is an open cover of $g(A)$. Let Φ be a partition of unity subordinate to this cover. If $\varphi = 0$ outside of $g(U)$, then, since g is 1-1, we have $(\varphi \cdot f) \circ g$

= 0 outside of U . Therefore the equation

$$\int_{g(U)} \varphi \cdot f = \int_U [(\varphi \cdot f) \circ g] |\det g'|.$$

can be written

$$\int_{g(A)} \varphi \cdot f = \int_A [(\varphi \cdot f) \circ g] |\det g'|.$$

Hence

$$\begin{aligned} \int_{g(A)} f &= \sum_{\varphi \in \Phi} \int_{g(A)} \varphi \cdot f = \sum_{\varphi \in \Phi} \int_A [(\varphi \cdot f) \circ g] |\det g'| \\ &= \sum_{\varphi \in \Phi} \int_A (\varphi \circ g)(f \circ g) |\det g'| \\ &= \int_A (f \circ g) |\det g'|. \end{aligned}$$

Remark. The theorem also follows from the assumption that

$$\int_V f = \int_{g^{-1}(V)} (f \circ g) |\det g'|$$

for V in some admissible cover of $g(A)$. This follows from (1) applied to g^{-1} .

2. It suffices to prove the theorem for the function $f = 1$.

Proof of (2). If the theorem holds for $f = 1$, it holds for constant functions. Let V be a rectangle in $g(A)$ and P a partition of V . For each subrectangle S of P let f_S be the constant function $m_S(f)$. Then

$$\begin{aligned} L(f, P) &= \sum_S m_S(f) \cdot v(S) = \sum_S \int_{\text{int } S} f_S \\ &= \sum_S \int_{g^{-1}(\text{int } S)} (f_S \circ g) |\det g'| \leq \sum_S \int_{g^{-1}(\text{int } S)} (f \circ g) |\det g'| \\ &\leq \int_{g^{-1}(V)} (f \circ g) |\det g'|. \end{aligned}$$

Since $\int_V f$ is the least upper bound of all $L(f, P)$, this proves that $\int_V f \leq \int_{g^{-1}(V)} (f \circ g) |\det g'|$. A similar argument, letting $f_S = M_S(f)$, shows that $\int_V f \geq \int_{g^{-1}(V)} (f \circ g) |\det g'|$. The result now follows from the above Remark.

3. If the theorem is true for $g: A \rightarrow \mathbf{R}^n$ and for $h: B \rightarrow \mathbf{R}^n$, where $g(A) \subset B$, then it is true for $h \circ g: A \rightarrow \mathbf{R}^n$.

Proof of (3).

$$\begin{aligned} \int_{h \circ g(A)} f &= \int_{h(g(A))} f = \int_{g(A)} (f \circ h) |\det h'| \\ &= \int_A [(f \circ h) \circ g] \cdot [|\det h'| \circ g] \cdot |\det g'| \\ &= \int_A f \circ (h \circ g) |\det (h \circ g)'|. \end{aligned}$$

4. The theorem is true if g is a linear transformation.

Proof of (4). By (1) and (2) it suffices to show for any open rectangle U that

$$\int_{g(U)} 1 = \int_U |\det g'|.$$

This is Problem 3-35.

Observations (3) and (4) together show that we may assume for any particular $a \in A$ that $g'(a)$ is the identity matrix: in fact, if T is the linear transformation $Dg(a)$, then $(T^{-1} \circ g)'(a) = I$; since the theorem is true for T , if it is true for $T^{-1} \circ g$ it will be true for g .

We are now prepared to give the proof, which preceeds by induction on n . The remarks before the statement of the theorem, together with (1) and (2), prove the case $n = 1$. Assuming the theorem in dimension $n - 1$, we prove it in dimension n . For each $a \in A$ we need only find an open set U with $a \in U \subset A$ for which the theorem is true. Moreover we may assume that $g'(a) = I$.

Define $h: A \rightarrow \mathbf{R}^n$ by $h(x) = (g^1(x), \dots, g^{n-1}(x), x^n)$. Then $h'(a) = I$. Hence in some open U' with $a \in U' \subset A$, the function h is 1-1 and $\det h'(x) \neq 0$. We can thus define $k: h(U') \rightarrow \mathbf{R}^n$ by $k(x) = (x^1, \dots, x^{n-1}, g^n(h^{-1}(x)))$ and $g = k \circ h$. We have thus expressed g as the composition

FIGURE 3-3

of two maps, each of which changes fewer than n coordinates (Figure 3-3).

We must attend to a few details to ensure that k is a function of the proper sort. Since

$$(g^n \circ h^{-1})'(h(a)) = (g^n)'(a) \cdot [h'(a)]^{-1} = (g^n)'(a),$$

we have $D_n(g^n \circ h^{-1})(h(a)) = D_n g^n(a) = 1$, so that $k'(h(a)) = I$. Thus in some open set V with $h(a) \in V \subset h(U')$, the function k is 1-1 and $\det k'(x) \neq 0$. Letting $U = k^{-1}(V)$ we now have $g = k \circ h$, where $h: U \rightarrow \mathbf{R}^n$ and $k: V \rightarrow \mathbf{R}^n$ and $h(U) \subset V$. By (3) it suffices to prove the theorem for h and k . We give the proof for h ; the proof for k is similar and easier.

Let $W \subset U$ be a rectangle of the form $D \times [a_n, b_n]$, where D is a rectangle in \mathbf{R}^{n-1} . By Fubini's theorem

$$\int_{h(W)} 1 = \int_{[a_n, b_n]} \left(\int_{h(D \times \{x^n\})} 1 \, dx^1 \cdots dx^{n-1} \right) dx^n.$$

Let $h_{x^n}: D \rightarrow \mathbf{R}^{n-1}$ be defined by $h_{x^n}(x^1, \dots, x^{n-1}) = (g^1(x^1, \dots, x^n), \dots, g^{n-1}(x^1, \dots, x^n))$. Then each h_{x^n} is clearly 1-1 and

$$\det (h_{x^n})'(x^1, \dots, x^{n-1}) = \det h'(x^1, \dots, x^n) \neq 0.$$

Moreover

$$\int_{h(D \times \{x^n\})} 1 \, dx^1 \cdots dx^{n-1} = \int_{h_{x^n}(D)} 1 \, dx^1 \cdots dx^{n-1}.$$

Applying the theorem in the case $n - 1$ therefore gives

$$\begin{aligned} \int_{h(W)} 1 &= \int_{[a_n, b_n]} \left(\int_{h_{x^n}(D)} 1 \, dx^1 \cdots dx^{n-1} \right) dx^n \\ &= \int_{[a_n, b_n]} \left(\int_D |\det (h_{x^n})'(x^1, \dots, x^{n-1})| \, dx^1 \cdots dx^{n-1} \right) dx^n \\ &= \int_{[a_n, b_n]} \left(\int_D |\det h'(x^1, \dots, x^n)| \, dx^1 \cdots dx^{n-1} \right) dx^n \\ &= \int_W |\det h'|. \quad \blacksquare \end{aligned}$$

The condition $\det g'(x) \neq 0$ may be eliminated from the

hypotheses of Theorem 3-13 by using the following theorem, which often plays an unexpected role.

3-14. Theorem (Sard's Theorem). *Let $g: A \rightarrow \mathbf{R}^n$ be continuously differentiable, where $A \subset \mathbf{R}^n$ is open, and let $B = \{x \in A: \det g'(x) = 0\}$. Then $g(B)$ has measure 0.*

Proof. Let $U \subset A$ be a closed rectangle such that all sides of U have length l , say. Let $\varepsilon > 0$. If N is sufficiently large and U is divided into N^n rectangles, with sides of length l/N , then for each of these rectangles S , if $x \in S$ we have

$$|Dg(x)(y - x) - g(y) + g(x)| < \varepsilon |x - y| \leq \varepsilon \sqrt{n} (l/N)$$

for all $y \in S$. If S intersects B we can choose $x \in S \cap B$; since $\det g'(x) = 0$, the set $\{Dg(x)(y - x): y \in S\}$ lies in an $(n - 1)$ -dimensional subspace V of \mathbf{R}^n . Therefore the set $\{g(y) - g(x): y \in S\}$ lies within $\varepsilon \sqrt{n} (l/N)$ of V , so that $\{g(y): y \in S\}$ lies within $\varepsilon \sqrt{n} (l/N)$ of the $(n - 1)$ -plane $V + g(x)$. On the other hand, by Lemma 2-10 there is a number M such that

$$|g(x) - g(y)| < M |x - y| \leq M \sqrt{n} (l/N).$$

Thus, if S intersects B , the set $\{g(y): y \in S\}$ is contained in a cylinder whose height is $< 2\varepsilon \sqrt{n} (l/N)$ and whose base is an $(n - 1)$ -dimensional sphere of radius $< M \sqrt{n} (l/N)$. This cylinder has volume $< C(l/N)^n \varepsilon$ for some constant C . There are at most N^n such rectangles S , so $g(U \cap B)$ lies in a set of volume $< C(l/N)^n \cdot \varepsilon \cdot N^n = Cl^n \cdot \varepsilon$. Since this is true for all $\varepsilon > 0$, the set $g(U \cap B)$ has measure 0. Since (Problem 3-13) we can cover all of A with a sequence of such rectangles U , the desired result follows from Theorem 3-4. ■

Theorem 3-14 is actually only the easy part of Sard's Theorem. The statement and proof of the deeper result will be found in [17], page 47.

Problems. 3-39. Use Theorem 3-14 to prove Theorem 3-13 without the assumption $\det g'(x) \neq 0$.

3-40. If $g: \mathbf{R}^n \rightarrow \mathbf{R}^n$ and $\det g'(x) \neq 0$, prove that in some open set containing x we can write $g = T \circ g_n \circ \cdots \circ g_1$, where g_i is of the form $g_i(x) = (x^1, \dots, f_i(x), \dots, x^n)$, and T is a linear transformation. Show that we can write $g = g_n \circ \cdots \circ g_1$ if and only if $g'(x)$ is a diagonal matrix.

3-41. Define $f: \{r: r > 0\} \times (0, 2\pi) \rightarrow \mathbf{R}^2$ by $f(r, \theta) = (r \cos \theta, r \sin \theta)$.

(a) Show that f is 1-1, compute $f'(r, \theta)$, and show that $\det f'(r, \theta) \neq 0$ for all (r, θ) . Show that $f(\{r: r > 0\} \times (0, 2\pi))$ is the set A of Problem 2-23.

(b) If $P = f^{-1}$, show that $P(x, y) = (r(x, y), \theta(x, y))$, where

$$r(x, y) = \sqrt{x^2 + y^2},$$

$$\theta(x, y) = \begin{cases} \arctan y/x & x > 0, y > 0, \\ \pi + \arctan y/x & x < 0, \\ 2\pi + \arctan y/x & x > 0, y < 0, \\ \pi/2 & x = 0, y > 0, \\ 3\pi/2 & x = 0, y < 0. \end{cases}$$

(Here \arctan denotes the inverse of the function $\tan: (-\pi/2, \pi/2) \rightarrow \mathbf{R}$.) Find $P'(x, y)$. The function P is called the **polar coordinate system** on A .

(c) Let $C \subset A$ be the region between the circles of radii r_1 and r_2 and the half-lines through 0 which make angles of θ_1 and θ_2 with the x -axis. If $h: C \rightarrow \mathbf{R}$ is integrable and $h(x, y) = g(r(x, y), \theta(x, y))$, show that

$$\int_C h = \int_{r_1}^{r_2} \int_{\theta_1}^{\theta_2} r g(r, \theta) d\theta dr.$$

If $B_r = \{(x, y): x^2 + y^2 \leq r^2\}$, show that

$$\int_{B_r} h = \int_0^r \int_0^{2\pi} r g(r, \theta) d\theta dr.$$

(d) If $C_r = [-r, r] \times [-r, r]$, show that

$$\int_{B_r} e^{-(x^2+y^2)} dx dy = \pi(1 - e^{-r^2})$$

and

$$\int_{C_r} e^{-(x^2+y^2)} dx dy = \left(\int_{-r}^r e^{-x^2} dx \right)^2.$$

(e) Prove that

$$\lim_{r \rightarrow \infty} \int_{B_r} e^{-(x^2+y^2)} dx dy = \lim_{r \rightarrow \infty} \int_{C_r} e^{-(x^2+y^2)} dx dy$$

and conclude that

$$\int_{-\infty}^{\infty} e^{-x^2} dx = \sqrt{\pi}.$$

Integration on Chains

ALGEBRAIC PRELIMINARIES

If V is a vector space (over \mathbf{R}), we will denote the k -fold product $V \times \cdots \times V$ by V^k . A function $T: V^k \rightarrow \mathbf{R}$ is called **multilinear** if for each i with $1 \leq i \leq k$ we have

$$\begin{aligned} T(v_1, \dots, v_i + v_i', \dots, v_k) &= T(v_1, \dots, v_i, \dots, v_k) \\ &\quad + T(v_1, \dots, v_i', \dots, v_k), \\ T(v_1, \dots, av_i, \dots, v_k) &= aT(v_1, \dots, v_i, \dots, v_k). \end{aligned}$$

A multilinear function $T: V^k \rightarrow \mathbf{R}$ is called a **k -tensor** on V and the set of all k -tensors, denoted $\mathfrak{J}^k(V)$, becomes a vector space (over \mathbf{R}) if for $S, T \in \mathfrak{J}^k(V)$ and $a \in \mathbf{R}$ we define

$$\begin{aligned} (S + T)(v_1, \dots, v_k) &= S(v_1, \dots, v_k) + T(v_1, \dots, v_k), \\ (aS)(v_1, \dots, v_k) &= a \cdot S(v_1, \dots, v_k). \end{aligned}$$

There is also an operation connecting the various spaces $\mathfrak{J}^k(V)$. If $S \in \mathfrak{J}^k(V)$ and $T \in \mathfrak{J}^l(V)$, we define the **tensor product** $S \otimes T \in \mathfrak{J}^{k+l}(V)$ by

$$\begin{aligned} S \otimes T(v_1, \dots, v_k, v_{k+1}, \dots, v_{k+l}) \\ = S(v_1, \dots, v_k) \cdot T(v_{k+1}, \dots, v_{k+l}). \end{aligned}$$

Note that the order of the factors S and T is crucial here since $S \otimes T$ and $T \otimes S$ are far from equal. The following properties of \otimes are left as easy exercises for the reader.

$$\begin{aligned}(S_1 + S_2) \otimes T &= S_1 \otimes T + S_2 \otimes T, \\ S \otimes (T_1 + T_2) &= S \otimes T_1 + S \otimes T_2, \\ (aS) \otimes T &= S \otimes (aT) = a(S \otimes T), \\ (S \otimes T) \otimes U &= S \otimes (T \otimes U).\end{aligned}$$

Both $(S \otimes T) \otimes U$ and $S \otimes (T \otimes U)$ are usually denoted simply $S \otimes T \otimes U$; higher-order products $T_1 \otimes \cdots \otimes T_r$ are defined similarly.

The reader has probably already noticed that $\mathfrak{I}^1(V)$ is just the dual space V^* . The operation \otimes allows us to express the other vector spaces $\mathfrak{I}^k(V)$ in terms of $\mathfrak{I}^1(V)$.

4-1 Theorem. *Let v_1, \dots, v_n be a basis for V , and let $\varphi_1, \dots, \varphi_n$ be the dual basis, $\varphi_i(v_j) = \delta_{ij}$. Then the set of all k -fold tensor products*

$$\varphi_{i_1} \otimes \cdots \otimes \varphi_{i_k} \quad 1 \leq i_1, \dots, i_k \leq n$$

is a basis for $\mathfrak{I}^k(V)$, which therefore has dimension n^k .

Proof. Note that

$$\begin{aligned}\varphi_{i_1} \otimes \cdots \otimes \varphi_{i_k}(v_{j_1}, \dots, v_{j_k}) &= \delta_{i_1, j_1} \cdots \delta_{i_k, j_k} \\ &= \begin{cases} 1 & \text{if } j_1 = i_1, \dots, j_k = i_k, \\ 0 & \text{otherwise.} \end{cases}\end{aligned}$$

If w_1, \dots, w_k are k vectors with $w_i = \sum_{j=1}^n a_{ij} v_j$ and T is in $\mathfrak{I}^k(V)$, then

$$\begin{aligned}T(w_1, \dots, w_k) &= \sum_{j_1, \dots, j_k=1}^n a_{1, j_1} \cdots a_{k, j_k} T(v_{j_1}, \dots, v_{j_k}) \\ &= \sum_{i_1, \dots, i_k=1}^n T(v_{i_1}, \dots, v_{i_k}) \cdot \varphi_{i_1} \otimes \cdots \otimes \varphi_{i_k}(w_1, \dots, w_k).\end{aligned}$$

Thus $T = \sum_{i_1, \dots, i_k=1}^n T(v_{i_1}, \dots, v_{i_k}) \cdot \varphi_{i_1} \otimes \cdots \otimes \varphi_{i_k}$.

Consequently the $\varphi_{i_1} \otimes \cdots \otimes \varphi_{i_k}$ span $\mathfrak{I}^k(V)$.

Suppose now that there are numbers a_{i_1, \dots, i_k} such that

$$\sum_{i_1, \dots, i_k=1}^n a_{i_1, \dots, i_k} \cdot \varphi_{i_1} \otimes \dots \otimes \varphi_{i_k} = 0.$$

Applying both sides of this equation to $(v_{j_1}, \dots, v_{j_k})$ yields $a_{j_1, \dots, j_k} = 0$. Thus the $\varphi_{i_1} \otimes \dots \otimes \varphi_{i_k}$ are linearly independent. ■

One important construction, familiar for the case of dual spaces, can also be made for tensors. If $f: V \rightarrow W$ is a linear transformation, a linear transformation $f^*: \mathfrak{J}^k(W) \rightarrow \mathfrak{J}^k(V)$ is defined by

$$f^*T(v_1, \dots, v_k) = T(f(v_1), \dots, f(v_k))$$

for $T \in \mathfrak{J}^k(W)$ and $v_1, \dots, v_k \in V$. It is easy to verify that $f^*(S \otimes T) = f^*S \otimes f^*T$.

The reader is already familiar with certain tensors, aside from members of V^* . The first example is the inner product $\langle, \rangle \in \mathfrak{J}^2(\mathbf{R}^n)$. On the grounds that any good mathematical commodity is worth generalizing, we define an **inner product** on V to be a 2-tensor T such that T is **symmetric**, that is $T(v, w) = T(w, v)$ for $v, w \in V$ and such that T is **positive-definite**, that is, $T(v, v) > 0$ if $v \neq 0$. We distinguish \langle, \rangle as the **usual inner product** on \mathbf{R}^n . The following theorem shows that our generalization is not too general.

4-2 Theorem. *If T is an inner product on V , there is a basis v_1, \dots, v_n for V such that $T(v_i, v_j) = \delta_{ij}$. (Such a basis is called **orthonormal** with respect to T .) Consequently there is an isomorphism $f: \mathbf{R}^n \rightarrow V$ such that $T(f(x), f(y)) = \langle x, y \rangle$ for $x, y \in \mathbf{R}^n$. In other words $f^*T = \langle, \rangle$.*

Proof. Let w_1, \dots, w_n be any basis for V . Define

$$\begin{aligned} w_1' &= w_1, \\ w_2' &= w_2 - \frac{T(w_1', w_2)}{T(w_1', w_1')} \cdot w_1', \\ w_3' &= w_3 - \frac{T(w_1', w_3)}{T(w_1', w_1')} \cdot w_1' - \frac{T(w_2', w_3)}{T(w_2', w_2')} \cdot w_2', \\ &\text{etc.} \end{aligned}$$

It is easy to check that $T(w_i', w_j') = 0$ if $i \neq j$ and $w_i' \neq 0$ so that $T(w_i', w_i') > 0$. Now define $v_i = w_i' / \sqrt{T(w_i', w_i')}$. The isomorphism f may be defined by $f(e_i) = v_i$. ■

Despite its importance, the inner product plays a far lesser role than another familiar, seemingly ubiquitous function, the tensor $\det \in \mathfrak{I}^n(\mathbb{R}^n)$. In attempting to generalize this function, we recall that interchanging two rows of a matrix changes the sign of its determinant. This suggests the following definition. A k -tensor $\omega \in \mathfrak{I}^k(V)$ is called **alternating** if

$$\begin{aligned} \omega(v_1, \dots, v_i, \dots, v_j, \dots, v_k) \\ = -\omega(v_1, \dots, v_j, \dots, v_i, \dots, v_k) \end{aligned} \quad \text{for all } v_1, \dots, v_k \in V.$$

(In this equation v_i and v_j are interchanged and all other v 's are left fixed.) The set of all alternating k -tensors is clearly a subspace $\Lambda^k(V)$ of $\mathfrak{I}^k(V)$. Since it requires considerable work to produce the determinant, it is not surprising that alternating k -tensors are difficult to write down. There is, however, a uniform way of expressing all of them. Recall that the sign of a permutation σ , denoted $\text{sgn } \sigma$, is $+1$ if σ is even and -1 if σ is odd. If $T \in \mathfrak{I}^k(V)$, we define $\text{Alt}(T)$ by

$$\text{Alt}(T)(v_1, \dots, v_k) = \frac{1}{k!} \sum_{\sigma \in S_k} \text{sgn } \sigma \cdot T(v_{\sigma(1)}, \dots, v_{\sigma(k)}),$$

where S_k is the set of all permutations of the numbers 1 to k .

4-3 Theorem

- (1) If $T \in \mathfrak{I}^k(V)$, then $\text{Alt}(T) \in \Lambda^k(V)$.
- (2) If $\omega \in \Lambda^k(V)$, then $\text{Alt}(\omega) = \omega$.
- (3) If $T \in \mathfrak{I}^k(V)$, then $\text{Alt}(\text{Alt}(T)) = \text{Alt}(T)$.

Proof

- (1) Let (i, j) be the permutation that interchanges i and j and leaves all other numbers fixed. If $\sigma \in S_k$, let $\sigma' = \sigma \cdot (i, j)$. Then

$$\begin{aligned}
& \text{Alt}(T)(v_1, \dots, v_j, \dots, v_i, \dots, v_k) \\
&= \frac{1}{k!} \sum_{\sigma \in S_k} \text{sgn } \sigma \cdot T(v_{\sigma(1)}, \dots, v_{\sigma(j)}, \dots, v_{\sigma(i)}, \dots, v_{\sigma(k)}) \\
&= \frac{1}{k!} \sum_{\sigma \in S_k} \text{sgn } \sigma \cdot T(v_{\sigma'(1)}, \dots, v_{\sigma'(i)}, \dots, v_{\sigma'(j)}, \dots, v_{\sigma'(k)}) \\
&= \frac{1}{k!} \sum_{\sigma' \in S_k} -\text{sgn } \sigma' \cdot T(v_{\sigma'(1)}, \dots, v_{\sigma'(k)}) \\
&= -\text{Alt}(T)(v_1, \dots, v_k).
\end{aligned}$$

(2) If $\omega \in \Lambda^k(V)$, and $\sigma = (i, j)$, then $\omega(v_{\sigma(1)}, \dots, v_{\sigma(k)}) = \text{sgn } \sigma \cdot \omega(v_1, \dots, v_k)$. Since every σ is a product of permutations of the form (i, j) , this equation holds of all σ . Therefore

$$\begin{aligned}
\text{Alt}(\omega)(v_1, \dots, v_k) &= \frac{1}{k!} \sum_{\sigma \in S_k} \text{sgn } \sigma \cdot \omega(v_{\sigma(1)}, \dots, v_{\sigma(k)}) \\
&= \frac{1}{k!} \sum_{\sigma \in S_k} \text{sgn } \sigma \cdot \text{sgn } \sigma \cdot \omega(v_1, \dots, v_k) \\
&= \omega(v_1, \dots, v_k).
\end{aligned}$$

(3) follows immediately from (1) and (2). ■

To determine the dimensions of $\Lambda^k(V)$, we would like a theorem analogous to Theorem 4-1. Of course, if $\omega \in \Lambda^k(V)$ and $\eta \in \Lambda^l(V)$, then $\omega \otimes \eta$ is usually not in $\Lambda^{k+l}(V)$. We will therefore define a new product, the **wedge product** $\omega \wedge \eta \in \Lambda^{k+l}(V)$ by

$$\omega \wedge \eta = \frac{(k+l)!}{k! l!} \text{Alt}(\omega \otimes \eta).$$

(The reason for the strange coefficient will appear later.) The following properties of \wedge are left as an exercise for the reader:

$$\begin{aligned}
(\omega_1 + \omega_2) \wedge \eta &= \omega_1 \wedge \eta + \omega_2 \wedge \eta, \\
\omega \wedge (\eta_1 + \eta_2) &= \omega \wedge \eta_1 + \omega \wedge \eta_2, \\
a\omega \wedge \eta &= \omega \wedge a\eta = a(\omega \wedge \eta), \\
\omega \wedge \eta &= (-1)^{kl} \eta \wedge \omega, \\
f^*(\omega \wedge \eta) &= f^*(\omega) \wedge f^*(\eta).
\end{aligned}$$

The equation $(\omega \wedge \eta) \wedge \theta = \omega \wedge (\eta \wedge \theta)$ is true but requires more work.

4-4 Theorem

(1) If $S \in \mathfrak{I}^k(V)$ and $T \in \mathfrak{I}^l(V)$ and $\text{Alt}(S) = 0$, then

$$\text{Alt}(S \otimes T) = \text{Alt}(T \otimes S) = 0.$$

(2) $\text{Alt}(\text{Alt}(\omega \otimes \eta) \otimes \theta) = \text{Alt}(\omega \otimes \eta \otimes \theta)$
 $= \text{Alt}(\omega \otimes \text{Alt}(\eta \otimes \theta)).$

(3) If $\omega \in \Lambda^k(V)$, $\eta \in \Lambda^l(V)$, and $\theta \in \Lambda^m(V)$, then

$$\begin{aligned} (\omega \wedge \eta) \wedge \theta &= \omega \wedge (\eta \wedge \theta) \\ &= \frac{(k + l + m)!}{k! l! m!} \text{Alt}(\omega \otimes \eta \otimes \theta). \end{aligned}$$

Proof

(1)

$$\begin{aligned} &(k + l)! \text{Alt}(S \otimes T)(v_1, \dots, v_{k+l}) \\ &= \sum_{\sigma \in S_{k+l}} \text{sgn } \sigma \cdot S(v_{\sigma(1)}, \dots, v_{\sigma(k)}) \cdot T(v_{\sigma(k+1)}, \dots, v_{\sigma(k+l)}). \end{aligned}$$

If $G \subset S_{k+l}$ consists of all σ which leave $k + 1, \dots, k + l$ fixed, then

$$\begin{aligned} &\sum_{\sigma \in G} \text{sgn } \sigma \cdot S(v_{\sigma(1)}, \dots, v_{\sigma(k)}) \cdot T(v_{\sigma(k+1)}, \dots, v_{\sigma(k+l)}) \\ &= \left[\sum_{\sigma' \in S_k} \text{sgn } \sigma' \cdot S(v_{\sigma'(1)}, \dots, v_{\sigma'(k)}) \right] \cdot T(v_{k+1}, \dots, v_{k+l}) \\ &= 0. \end{aligned}$$

Suppose now that $\sigma_0 \notin G$. Let $G \cdot \sigma_0 = \{\sigma \cdot \sigma_0 : \sigma \in G\}$ and let $v_{\sigma_0(1)}, \dots, v_{\sigma_0(k+l)} = w_1, \dots, w_{k+l}$. Then

$$\begin{aligned} &\sum_{\sigma \in G \cdot \sigma_0} \text{sgn } \sigma \cdot S(v_{\sigma(1)}, \dots, v_{\sigma(k)}) \cdot T(v_{\sigma(k+1)}, \dots, v_{\sigma(k+l)}) \\ &= \left[\text{sgn } \sigma_0 \cdot \sum_{\sigma' \in G} \text{sgn } \sigma' \cdot S(w_{\sigma'(1)}, \dots, w_{\sigma'(k)}) \right] \\ &\quad \cdot T(w_{k+1}, \dots, w_{k+l}) \\ &= 0. \end{aligned}$$

Notice that $G \cap G \cdot \sigma_0 = \emptyset$. In fact, if $\sigma \in G \cap G \cdot \sigma_0$, then $\sigma = \sigma' \cdot \sigma_0$ for some $\sigma' \in G$ and $\sigma_0 = \sigma \cdot (\sigma')^{-1} \in G$, a contradiction. We can then continue in this way, breaking S_{k+l} up into disjoint subsets; the sum over each subset is 0, so that the sum over S_{k+l} is 0. The relation $\text{Alt}(T \otimes S) = 0$ is proved similarly.

(2) We have

$$\text{Alt}(\text{Alt}(\eta \otimes \theta) - \eta \otimes \theta) = \text{Alt}(\eta \otimes \theta) - \text{Alt}(\eta \otimes \theta) = 0.$$

Hence by (1) we have

$$\begin{aligned} 0 &= \text{Alt}(\omega \otimes [\text{Alt}(\eta \otimes \theta) - \eta \otimes \theta]) \\ &= \text{Alt}(\omega \otimes \text{Alt}(\eta \otimes \theta)) - \text{Alt}(\omega \otimes \eta \otimes \theta). \end{aligned}$$

The other equality is proved similarly.

$$\begin{aligned} (3) \quad (\omega \wedge \eta) \wedge \theta &= \frac{(k+l+m)!}{(k+l)!m!} \text{Alt}((\omega \wedge \eta) \otimes \theta) \\ &= \frac{(k+l+m)!}{(k+l)!m!} \frac{(k+l)!}{k!l!} \text{Alt}(\omega \otimes \eta \otimes \theta). \end{aligned}$$

The other equality is proved similarly. ■

Naturally $\omega \wedge (\eta \wedge \theta)$ and $(\omega \wedge \eta) \wedge \theta$ are both denoted simply $\omega \wedge \eta \wedge \theta$, and higher-order products $\omega_1 \wedge \cdots \wedge \omega_r$ are defined similarly. If v_1, \dots, v_n is a basis for V and $\varphi_1, \dots, \varphi_n$ is the dual basis, a basis for $\Lambda^k(V)$ can now be constructed quite easily.

4-5 Theorem. *The set of all*

$$\varphi_{i_1} \wedge \cdots \wedge \varphi_{i_k} \quad 1 \leq i_1 < i_2 < \cdots < i_k \leq n$$

is a basis for $\Lambda^k(V)$, which therefore has dimension

$$\binom{n}{k} = \frac{n!}{k!(n-k)!}.$$

Proof. If $\omega \in \Lambda^k(V) \subset \mathcal{J}^k(V)$, then we can write

$$\omega = \sum_{i_1, \dots, i_k} a_{i_1, \dots, i_k} \varphi_{i_1} \otimes \cdots \otimes \varphi_{i_k}.$$

Thus

$$\omega = \text{Alt}(\omega) = \sum_{i_1, \dots, i_k} a_{i_1, \dots, i_k} \text{Alt}(\varphi_{i_1} \otimes \dots \otimes \varphi_{i_k}).$$

Since each $\text{Alt}(\varphi_{i_1} \otimes \dots \otimes \varphi_{i_k})$ is a constant times one of the $\varphi_{i_1} \wedge \dots \wedge \varphi_{i_k}$, these elements span $\Lambda^k(V)$. Linear independence is proved as in Theorem 4-1 (cf. Problem 4-1). ■

If V has dimension n , it follows from Theorem 4-5 that $\Lambda^n(V)$ has dimension 1. Thus all alternating n -tensors on V are multiples of any non-zero one. Since the determinant is an example of such a member of $\Lambda^n(\mathbf{R}^n)$, it is not surprising to find it in the following theorem.

4-6 Theorem. *Let v_1, \dots, v_n be a basis for V , and let $\omega \in \Lambda^n(V)$. If $w_i = \sum_{j=1}^n a_{ij}v_j$ are n vectors in V , then*

$$\omega(w_1, \dots, w_n) = \det(a_{ij}) \cdot \omega(v_1, \dots, v_n).$$

Proof. Define $\eta \in \mathcal{T}^n(\mathbf{R}^n)$ by

$$\begin{aligned} \eta((a_{11}, \dots, a_{1n}), \dots, (a_{n1}, \dots, a_{nn})) \\ = \omega(\sum a_{1j}v_j, \dots, \sum a_{nj}v_j). \end{aligned}$$

Clearly $\eta \in \Lambda^n(\mathbf{R}^n)$ so $\eta = \lambda \cdot \det$ for some $\lambda \in \mathbf{R}$ and $\lambda = \eta(e_1, \dots, e_n) = \omega(v_1, \dots, v_n)$. ■

Theorem 4-6 shows that a non-zero $\omega \in \Lambda^n(V)$ splits the bases of V into two disjoint groups, those with $\omega(v_1, \dots, v_n) > 0$ and those for which $\omega(v_1, \dots, v_n) < 0$; if v_1, \dots, v_n and w_1, \dots, w_n are two bases and $A = (a_{ij})$ is defined by $w_i = \sum a_{ij}v_j$, then v_1, \dots, v_n and w_1, \dots, w_n are in the same group if and only if $\det A > 0$. This criterion is independent of ω and can always be used to divide the bases of V into two disjoint groups. Either of these two groups is called an **orientation** for V . The orientation to which a basis v_1, \dots, v_n belongs is denoted $[v_1, \dots, v_n]$ and the

other orientation is denoted $-[v_1, \dots, v_n]$. In \mathbf{R}^n we define the **usual orientation** as $[e_1, \dots, e_n]$.

The fact that $\dim \Lambda^n(\mathbf{R}^n) = 1$ is probably not new to you, since \det is often defined as the unique element $\omega \in \Lambda^n(\mathbf{R}^n)$ such that $\omega(e_1, \dots, e_n) = 1$. For a general vector space V there is no extra criterion of this sort to distinguish a particular $\omega \in \Lambda^n(V)$. Suppose, however, that an inner product T for V is given. If v_1, \dots, v_n and w_1, \dots, w_n are two bases which are orthonormal with respect to T , and the matrix $A = (a_{ij})$ is defined by $w_i = \sum_{j=1}^n a_{ij}v_j$, then

$$\begin{aligned} \delta_{ij} = T(w_i, w_j) &= \sum_{k,l=1}^n a_{ik}a_{jl}T(v_k, v_l) \\ &= \sum_{k=1}^n a_{ik}a_{jk}. \end{aligned}$$

In other words, if A^T denotes the transpose of the matrix A , then we have $A \cdot A^T = I$, so $\det A = \pm 1$. It follows from Theorem 4-6 that if $\omega \in \Lambda^n(V)$ satisfies $\omega(v_1, \dots, v_n) = \pm 1$, then $\omega(w_1, \dots, w_n) = \pm 1$. If an orientation μ for V has also been given, it follows that there is a unique $\omega \in \Lambda^n(V)$ such that $\omega(v_1, \dots, v_n) = 1$ whenever v_1, \dots, v_n is an orthonormal basis such that $[v_1, \dots, v_n] = \mu$. This unique ω is called the **volume element** of V , determined by the inner product T and orientation μ . Note that \det is the volume element of \mathbf{R}^n determined by the usual inner product and usual orientation, and that $|\det(v_1, \dots, v_n)|$ is the volume of the parallelipiped spanned by the line segments from 0 to each of v_1, \dots, v_n .

We conclude this section with a construction which we will restrict to \mathbf{R}^n . If $v_1, \dots, v_{n-1} \in \mathbf{R}^n$ and φ is defined by

$$\varphi(w) = \det \begin{pmatrix} v_1 \\ \vdots \\ v_{n-1} \\ w \end{pmatrix},$$

then $\varphi \in \Lambda^1(\mathbf{R}^n)$; therefore there is a unique $z \in \mathbf{R}^n$ such that

$$\langle w, z \rangle = \varphi(w) = \det \begin{pmatrix} v_1 \\ \vdots \\ v_{n-1} \\ w \end{pmatrix}$$

This z is denoted $v_1 \times \cdots \times v_{n-1}$ and called the **cross product** of v_1, \dots, v_{n-1} . The following properties are immediate from the definition:

$$\begin{aligned} v_{\sigma(1)} \times \cdots \times v_{\sigma(n-1)} &= \operatorname{sgn} \sigma \cdot v_1 \times \cdots \times v_{n-1}, \\ v_1 \times \cdots \times av_i \times \cdots \times v_{n-1} &= a \cdot (v_1 \times \cdots \times v_{n-1}), \\ v_1 \times \cdots \times (v_i + v_i') \times \cdots \times v_{n-1} \\ &= v_1 \times \cdots \times v_i \times \cdots \times v_{n-1} \\ &\quad + v_1 \times \cdots \times v_i' \times \cdots \times v_{n-1}. \end{aligned}$$

It is uncommon in mathematics to have a “product” that depends on more than two factors. In the case of two vectors $v, w \in \mathbf{R}^3$, we obtain a more conventional looking product, $v \times w \in \mathbf{R}^3$. For this reason it is sometimes maintained that the cross product can be defined only in \mathbf{R}^3 .

Problems. 4-1.* Let e_1, \dots, e_n be the usual basis of \mathbf{R}^n and let $\varphi_1, \dots, \varphi_n$ be the dual basis.

(a) Show that $\varphi_{i_1} \wedge \cdots \wedge \varphi_{i_k} (e_{i_1}, \dots, e_{i_k}) = 1$. What would the right side be if the factor $(k+l)!/k!l!$ did not appear in the definition of \wedge ?

(b) Show that $\varphi_{i_1} \wedge \cdots \wedge \varphi_{i_k} (v_1, \dots, v_k)$ is the determinant

of the $k \times k$ minor of $\begin{pmatrix} v_1 \\ \vdots \\ v_k \end{pmatrix}$ obtained by selecting columns

i_1, \dots, i_k .

4-2. If $f: V \rightarrow V$ is a linear transformation and $\dim V = n$, then $f^*: \Lambda^n(V) \rightarrow \Lambda^n(V)$ must be multiplication by some constant c . Show that $c = \det f$.

- 4-3. If $\omega \in \Lambda^n(V)$ is the volume element determined by T and μ , and $w_1, \dots, w_n \in V$, show that

$$|\omega(w_1, \dots, w_n)| = \sqrt{\det(g_{ij})},$$

where $g_{ij} = T(w_i, w_j)$. *Hint:* If v_1, \dots, v_n is an orthonormal basis and $w_i = \sum_{j=1}^n a_{ij}v_j$, show that $g_{ij} = \sum_{k=1}^n a_{ik}a_{kj}$.

- 4-4. If ω is the volume element of V determined by T and μ , and $f: \mathbf{R}^n \rightarrow V$ is an isomorphism such that $f^*T = \langle, \rangle$ and such that $[f(e_1), \dots, f(e_n)] = \mu$, show that $f^*\omega = \det$.

- 4-5. If $c: [0,1] \rightarrow (\mathbf{R}^n)^n$ is continuous and each $(c^1(t), \dots, c^n(t))$ is a basis for \mathbf{R}^n , show that $[c^1(0), \dots, c^n(0)] = [c^1(1), \dots, c^n(1)]$.

Hint: Consider $\det \circ c$.

- 4-6. (a) If $v \in \mathbf{R}^2$, what is $v \times$?

(b) If $v_1, \dots, v_{n-1} \in \mathbf{R}^n$ are linearly independent, show that $[v_1, \dots, v_{n-1}, v_1 \times \dots \times v_{n-1}]$ is the usual orientation of \mathbf{R}^n .

- 4-7. Show that every non-zero $\omega \in \Lambda^n(V)$ is the volume element determined by some inner product T and orientation μ for V .

- 4-8. If $\omega \in \Lambda^n(V)$ is a volume element, define a "cross product" $v_1 \times \dots \times v_{n-1}$ in terms of ω .

- 4-9.* Deduce the following properties of the cross product in \mathbf{R}^3 :

$$\begin{array}{lll} \text{(a)} & e_1 \times e_1 = 0 & e_2 \times e_1 = -e_3 & e_3 \times e_1 = e_2 \\ & e_1 \times e_2 = e_3 & e_2 \times e_2 = 0 & e_3 \times e_2 = -e_1 \\ & e_1 \times e_3 = -e_2 & e_2 \times e_3 = e_1 & e_3 \times e_3 = 0. \end{array}$$

$$\begin{aligned} \text{(b)} \quad v \times w &= (v^2w^3 - v^3w^2)e_1 \\ &\quad + (v^3w^1 - v^1w^3)e_2 \\ &\quad + (v^1w^2 - v^2w^1)e_3. \end{aligned}$$

$$\text{(c)} \quad |v \times w| = |v| \cdot |w| \cdot |\sin \theta|, \text{ where } \theta = \angle(v, w).$$

$$\langle v \times w, v \rangle = \langle v \times w, w \rangle = 0.$$

$$\text{(d)} \quad \langle v, w \times z \rangle = \langle w, z \times v \rangle = \langle z, v \times w \rangle$$

$$v \times (w \times z) = \langle v, z \rangle w - \langle v, w \rangle z$$

$$(v \times w) \times z = \langle v, z \rangle w - \langle w, z \rangle v.$$

$$\text{(e)} \quad |v \times w| = \sqrt{\langle v, v \rangle \cdot \langle w, w \rangle - \langle v, w \rangle^2}.$$

- 4-10. If $w_1, \dots, w_{n-1} \in \mathbf{R}^n$, show that

$$|w_1 \times \dots \times w_{n-1}| = \sqrt{\det(g_{ij})},$$

where $g_{ij} = \langle w_i, w_j \rangle$. *Hint:* Apply Problem 4-3 to a certain $(n-1)$ -dimensional subspace of \mathbf{R}^n .

- 4-11. If T is an inner product on V , a linear transformation $f: V \rightarrow V$ is called **self-adjoint** (with respect to T) if $T(x, f(y)) = T(f(x), y)$ for $x, y \in V$. If v_1, \dots, v_n is an orthonormal basis and $A = (a_{ij})$ is the matrix of f with respect to this basis, show that $a_{ij} = a_{ji}$.

- 4-12. If $f_1, \dots, f_{n-1}: \mathbf{R}^m \rightarrow \mathbf{R}^n$, define $f_1 \times \dots \times f_{n-1}: \mathbf{R}^m \rightarrow \mathbf{R}^n$ by $f_1 \times \dots \times f_{n-1}(p) = f_1(p) \times \dots \times f_{n-1}(p)$. Use Problem 2-14 to derive a formula for $D(f_1 \times \dots \times f_{n-1})$ when f_1, \dots, f_{n-1} are differentiable.

FIELDS AND FORMS

If $p \in \mathbf{R}^n$, the set of all pairs (p, v) , for $v \in \mathbf{R}^n$, is denoted \mathbf{R}^n_p , and called the **tangent space** of \mathbf{R}^n at p . This set is made into a vector space in the most obvious way, by defining

$$\begin{aligned}(p, v) + (p, w) &= (p, v + w), \\ a \cdot (p, v) &= (p, av).\end{aligned}$$

A vector $v \in \mathbf{R}^n$ is often pictured as an arrow from 0 to v ; the vector $(p, v) \in \mathbf{R}^n_p$ may be pictured (Figure 4-1) as an arrow with the same direction and length, but with initial point p . This arrow goes from p to the point $p + v$, and we therefore

FIGURE 4-1

define $p + v$ to be the **end point** of (p, v) . We will usually write (p, v) as v_p (read: the vector v at p).

The vector space \mathbf{R}^n_p is so closely allied to \mathbf{R}^n that many of the structures on \mathbf{R}^n have analogues on \mathbf{R}^n_p . In particular the **usual inner product** $\langle \cdot, \cdot \rangle_p$ for \mathbf{R}^n_p is defined by $\langle v_p, w_p \rangle_p = \langle v, w \rangle$, and the **usual orientation** for \mathbf{R}^n_p is $[(e_1)_p, \dots, (e_n)_p]$.

Any operation which is possible in a vector space may be performed in each \mathbf{R}^n_p , and most of this section is merely an elaboration of this theme. About the simplest operation in a vector space is the selection of a vector from it. If such a selection is made in each \mathbf{R}^n_p , we obtain a **vector field** (Figure 4-2). To be precise, a vector field is a function F such that $F(p) \in \mathbf{R}^n_p$ for each $p \in \mathbf{R}^n$. For each p there are numbers $F^1(p), \dots, F^n(p)$ such that

$$F(p) = F^1(p) \cdot (e_1)_p + \dots + F^n(p) \cdot (e_n)_p.$$

We thus obtain n **component functions** $F^i: \mathbf{R}^n \rightarrow \mathbf{R}$. The vector field F is called continuous, differentiable, etc., if the functions F^i are. Similar definitions can be made for a vector field defined only on an open subset of \mathbf{R}^n . Operations on vectors yield operations on vector fields when applied at each point separately. For example, if F and G are vector fields

FIGURE 4-2

and f is a function, we define

$$\begin{aligned}(F + G)(p) &= F(p) + G(p), \\ \langle F, G \rangle(p) &= \langle F(p), G(p) \rangle, \\ (f \cdot F)(p) &= f(p)F(p).\end{aligned}$$

If F_1, \dots, F_{n-1} are vector fields on \mathbf{R}^n , then we can similarly define

$$(F_1 \times \dots \times F_{n-1})(p) = F_1(p) \times \dots \times F_{n-1}(p).$$

Certain other definitions are standard and useful. We define the **divergence**, $\operatorname{div} F$ of F , as $\sum_{i=1}^n D_i F^i$. If we introduce the formal symbolism

$$\nabla = \sum_{i=1}^n D_i \cdot e_i,$$

we can write, symbolically, $\operatorname{div} F = \langle \nabla, F \rangle$. If $n = 3$ we write, in conformity with this symbolism,

$$\begin{aligned}(\nabla \times F)(p) &= (D_2 F^3 - D_3 F^2)(e_1)_p \\ &\quad + (D_3 F^1 - D_1 F^3)(e_2)_p \\ &\quad + (D_1 F^2 - D_2 F^1)(e_3)_p.\end{aligned}$$

The vector field $\nabla \times F$ is called $\operatorname{curl} F$. The names “divergence” and “curl” are derived from physical considerations which are explained at the end of this book.

Many similar considerations may be applied to a function ω with $\omega(p) \in \Lambda^k(\mathbf{R}^n_p)$; such a function is called a **k -form** on \mathbf{R}^n , or simply a **differential form**. If $\varphi_1(p), \dots, \varphi_n(p)$ is the dual basis to $(e_1)_p, \dots, (e_n)_p$, then

$$\omega(p) = \sum_{i_1 < \dots < i_k} \omega_{i_1, \dots, i_k}(p) \cdot [\varphi_{i_1}(p) \wedge \dots \wedge \varphi_{i_k}(p)]$$

for certain functions ω_{i_1, \dots, i_k} ; the form ω is called continuous, differentiable, etc., if these functions are. We shall usually assume tacitly that forms and vector fields are differentiable, and “differentiable” will henceforth mean “ C^∞ ”; this is a simplifying assumption that eliminates the need for counting how many times a function is differentiated in a proof. The sum $\omega + \eta$, product $f \cdot \omega$, and wedge product $\omega \wedge \eta$ are defined

in the obvious way. A function f is considered to be a 0-form and $f \cdot \omega$ is also written $f \wedge \omega$.

If $f: \mathbf{R}^n \rightarrow \mathbf{R}$ is differentiable, then $Df(p) \in \Lambda^1(\mathbf{R}^n)$. By a minor modification we therefore obtain a 1-form df , defined by

$$df(p)(v_p) = Df(p)(v).$$

Let us consider in particular the 1-forms $d\pi^i$. It is customary to let x^i denote the function π^i . (On \mathbf{R}^3 we often denote x^1 , x^2 , and x^3 by x , y , and z .) This standard notation has obvious disadvantages but it allows many classical results to be expressed by formulas of equally classical appearance. Since $dx^i(p)(v_p) = d\pi^i(p)(v_p) = D\pi^i(p)(v) = v^i$, we see that $dx^1(p), \dots, dx^n(p)$ is just the dual basis to $(e_1)_p, \dots, (e_n)_p$. Thus every k -form ω can be written

$$\omega = \sum_{i_1 < \dots < i_k} \omega_{i_1, \dots, i_k} dx^{i_1} \wedge \dots \wedge dx^{i_k}.$$

The expression for df is of particular interest.

4-7 Theorem. *If $f: \mathbf{R}^n \rightarrow \mathbf{R}$ is differentiable, then*

$$df = D_1 f \cdot dx^1 + \dots + D_n f \cdot dx^n.$$

In classical notation,

$$df = \frac{\partial f}{\partial x^1} dx^1 + \dots + \frac{\partial f}{\partial x^n} dx^n.$$

Proof. $df(p)(v_p) = Df(p)(v) = \sum_{i=1}^n v^i \cdot D_i f(p)$
 $= \sum_{i=1}^n dx^i(p)(v_p) \cdot D_i f(p). \quad \blacksquare$

If we consider now a differentiable function $f: \mathbf{R}^n \rightarrow \mathbf{R}^m$ we have a linear transformation $Df(p): \mathbf{R}^n \rightarrow \mathbf{R}^m$. Another minor modification therefore produces a linear transformation $f_*: \mathbf{R}^n_p \rightarrow \mathbf{R}^m_{f(p)}$ defined by

$$f_*(v_p) \doteq (Df(p)(v))_{f(p)}.$$

This linear transformation induces a linear transformation $f^*: \Lambda^k(\mathbf{R}^m_{f(p)}) \rightarrow \Lambda^k(\mathbf{R}^n_p)$. If ω is a k -form on \mathbf{R}^m we can therefore define a k -form $f^*\omega$ on \mathbf{R}^n by $(f^*\omega)(p) = f^*(\omega(f(p)))$.

Recall this means that if $v_1, \dots, v_k \in \mathbf{R}^n_p$, then we have $f^*\omega(p)(v_1, \dots, v_k) = \omega(f(p))(f_*(v_1), \dots, f_*(v_k))$. As an antidote to the abstractness of these definitions we present a theorem, summarizing the important properties of f^* , which allows explicit calculations of $f^*\omega$.

4-8 Theorem. *If $f: \mathbf{R}^n \rightarrow \mathbf{R}^m$ is differentiable, then*

$$(1) \quad f^*(dx^i) = \sum_{j=1}^n D_j f^i \cdot dx^j = \sum_{j=1}^n \frac{\partial f^i}{\partial x^j} dx^j.$$

$$(2) \quad f^*(\omega_1 + \omega_2) = f^*(\omega_1) + f^*(\omega_2).$$

$$(3) \quad f^*(g \cdot \omega) = (g \circ f) \cdot f^*\omega.$$

$$(4) \quad f^*(\omega \wedge \eta) = f^*\omega \wedge f^*\eta.$$

Proof

$$\begin{aligned} (1) \quad f^*(dx^i)(p)(v_p) &= dx^i(f(p))(f_*v_p) \\ &= dx^i(f(p))(\sum_{j=1}^n v^j \cdot D_j f^i(p), \dots, \sum_{j=1}^n v^j \cdot D_j f^m(p))_{f(p)} \\ &= \sum_{j=1}^n v^j \cdot D_j f^i(p) \\ &= \sum_{j=1}^n D_j f^i(p) \cdot dx^j(p)(v_p). \end{aligned}$$

The proofs of (2), (3), and (4) are left to the reader. ■

By repeatedly applying Theorem 4-8 we have, for example,

$$\begin{aligned} f^*(P dx^1 \wedge dx^2 + Q dx^2 \wedge dx^3) &= (P \circ f)[f^*(dx^1) \wedge f^*(dx^2)] \\ &\quad + (Q \circ f)[f^*(dx^2) \wedge f^*(dx^3)]. \end{aligned}$$

The expression obtained by expanding out each $f^*(dx^i)$ is quite complicated. (It is helpful to remember, however, that we have $dx^i \wedge dx^i = (-1)dx^i \wedge dx^i = 0$.) In one special case it will be worth our while to make an explicit evaluation.

4-9 Theorem. *If $f: \mathbf{R}^n \rightarrow \mathbf{R}^n$ is differentiable, then*

$$f^*(h dx^1 \wedge \dots \wedge dx^n) = (h \circ f)(\det f') dx^1 \wedge \dots \wedge dx^n.$$

Proof. Since

$$f^*(h dx^1 \wedge \dots \wedge dx^n) = (h \circ f)f^*(dx^1 \wedge \dots \wedge dx^n),$$

it suffices to show that

$$f^*(dx^1 \wedge \cdots \wedge dx^n) = (\det f') dx^1 \wedge \cdots \wedge dx^n.$$

Let $p \in \mathbf{R}^n$ and let $A = (a_{ij})$ be the matrix of $f'(p)$. Here, and whenever convenient and not confusing, we shall omit “ p ” in $dx^1 \wedge \cdots \wedge dx^n(p)$, etc. Then

$$\begin{aligned} f^*(dx^1 \wedge \cdots \wedge dx^n)(e_1, \dots, e_n) &= dx^1 \wedge \cdots \wedge dx^n(f_*e_1, \dots, f_*e_n) \\ &= dx^1 \wedge \cdots \wedge \left(\sum_{i=1}^n a_{i1}e_i, \dots, \sum_{i=1}^n a_{in}e_i \right) \\ &= \det(a_{ij}) \cdot dx^1 \wedge \cdots \wedge dx^n(e_1, \dots, e_n), \end{aligned}$$

by Theorem 4-6. ■

An important construction associated with forms is a generalization of the operator d which changes 0-forms into 1-forms. If

$$\omega = \sum_{i_1 < \cdots < i_k} \omega_{i_1, \dots, i_k} dx^{i_1} \wedge \cdots \wedge dx^{i_k},$$

we define a $(k+1)$ -form $d\omega$, the **differential** of ω , by

$$\begin{aligned} d\omega &= \sum_{i_1 < \cdots < i_k} d\omega_{i_1, \dots, i_k} \wedge dx^{i_1} \wedge \cdots \wedge dx^{i_k} \\ &= \sum_{i_1 < \cdots < i_k} \sum_{\alpha=1}^n D_\alpha(\omega_{i_1, \dots, i_k}) \cdot dx^\alpha \wedge dx^{i_1} \wedge \cdots \wedge dx^{i_k}. \end{aligned}$$

4-10 Theorem

- (1) $d(\omega + \eta) = d\omega + d\eta$.
- (2) If ω is a k -form and η is an l -form, then

$$d(\omega \wedge \eta) = d\omega \wedge \eta + (-1)^k \omega \wedge d\eta.$$

- (3) $d(d\omega) = 0$. Briefly, $d^2 = 0$.
- (4) If ω is a k -form on \mathbf{R}^m and $f: \mathbf{R}^n \rightarrow \mathbf{R}^m$ is differentiable, then $f^*(d\omega) = d(f^*\omega)$.

Proof

- (1) Left to the reader.
- (2) The formula is true if $\omega = dx^{i_1} \wedge \cdots \wedge dx^{i_k}$ and $\eta = dx^{j_1} \wedge \cdots \wedge dx^{j_l}$, since all terms vanish. The formula is easily checked when ω is a 0-form. The general formula may be derived from (1) and these two observations.
- (3) Since

$$d\omega = \sum_{i_1 < \cdots < i_k} \sum_{\alpha=1}^n D_{\alpha}(\omega_{i_1, \dots, i_k}) dx^{\alpha} \wedge dx^{i_1} \wedge \cdots \wedge dx^{i_k},$$

we have

$$d(d\omega) = \sum_{i_1 < \cdots < i_k} \sum_{\alpha=1}^n \sum_{\beta=1}^n D_{\alpha, \beta}(\omega_{i_1, \dots, i_k}) dx^{\beta} \wedge dx^{\alpha} \wedge dx^{i_1} \wedge \cdots \wedge dx^{i_k}.$$

In this sum the terms

$$D_{\alpha, \beta}(\omega_{i_1, \dots, i_k}) dx^{\beta} \wedge dx^{\alpha} \wedge dx^{i_1} \wedge \cdots \wedge dx^{i_k}$$

and

$$D_{\beta, \alpha}(\omega_{i_1, \dots, i_k}) dx^{\alpha} \wedge dx^{\beta} \wedge dx^{i_1} \wedge \cdots \wedge dx^{i_k}$$

cancel in pairs.

- (4) This is clear if ω is a 0-form. Suppose, inductively, that (4) is true when ω is a k -form. It suffices to prove (4) for a $(k+1)$ -form of the type $\omega \wedge dx^i$. We have

$$\begin{aligned} f^*(d(\omega \wedge dx^i)) &= f^*(d\omega \wedge dx^i + (-1)^k \omega \wedge d(dx^i)) \\ &= f^*(d\omega \wedge dx^i) = f^*(d\omega) \wedge f^*(dx^i) \\ &= d(f^*\omega \wedge f^*(dx^i)) \quad \text{by (2) and (3)} \\ &= d(f^*(\omega \wedge dx^i)). \quad \blacksquare \end{aligned}$$

A form ω is called **closed** if $d\omega = 0$ and **exact** if $\omega = d\eta$, for some η . Theorem 4-10 shows that every exact form is closed, and it is natural to ask whether, conversely, every closed form is exact. If ω is the 1-form $P dx + Q dy$ on \mathbf{R}^2 , then

$$\begin{aligned} d\omega &= (D_1P dx + D_2P dy) \wedge dx + (D_1Q dx + D_2Q dy) \wedge dy \\ &= (D_1Q - D_2P) dx \wedge dy. \end{aligned}$$

Thus, if $d\omega = 0$, then $D_1Q = D_2P$. Problems 2-21 and 3-34 show that there is a 0-form f such that $\omega = df = D_1f dx + D_2f dy$. If ω is defined only on a subset of \mathbf{R}^2 , however, such a function may not exist. The classical example is the form

$$\omega = \frac{-y}{x^2 + y^2} dx + \frac{x}{x^2 + y^2} dy$$

defined on $\mathbf{R}^2 - 0$. This form is usually denoted $d\theta$ (where θ is defined in Problem 3-41), since (Problem 4-21) it equals $d\theta$ on the set $\{(x,y): x < 0, \text{ or } x \geq 0 \text{ and } y \neq 0\}$, where θ is defined. Note, however, that θ cannot be defined continuously on all of $\mathbf{R}^2 - 0$. If $\omega = df$ for some function $f: \mathbf{R}^2 - 0 \rightarrow \mathbf{R}$, then $D_1f = D_1\theta$ and $D_2f = D_2\theta$, so $f = \theta + \text{constant}$, showing that such an f cannot exist.

Suppose that $\omega = \sum_{i=1}^n \omega_i dx^i$ is a 1-form on \mathbf{R}^n and ω happens to equal $df = \sum_{i=1}^n D_i f \cdot dx^i$. We can clearly assume that $f(0) = 0$. As in Problem 2-35, we have

$$\begin{aligned} f(x) &= \int_0^1 \frac{d}{dt} f(tx) dt \\ &= \int_0^1 \sum_{i=1}^n D_i f(tx) \cdot x^i dt \\ &= \int_0^1 \sum_{i=1}^n \omega_i(tx) \cdot x^i dt. \end{aligned}$$

This suggests that in order to find f , given ω , we consider the function $I\omega$, defined by

$$I\omega(x) = \int_0^1 \sum_{i=1}^n \omega_i(tx) \cdot x^i dt.$$

Note that the definition of $I\omega$ makes sense if ω is defined only on an open set $A \subset \mathbf{R}^n$ with the property that whenever $x \in A$, the line segment from 0 to x is contained in A ; such an open set is called **star-shaped** with respect to 0 (Figure 4-3). A somewhat involved calculation shows that (on a star-shaped open set) we have $\omega = d(I\omega)$ provided that ω satisfies the necessary condition $d\omega = 0$. The calculation, as well as the definition of $I\omega$, may be generalized considerably:

FIGURE 4-3

4-11 Theorem (Poincaré Lemma). *If $A \subset \mathbf{R}^n$ is an open set star-shaped with respect to 0, then every closed form on A is exact.*

Proof. We will define a function I from l -forms to $(l-1)$ -forms (for each l), such that $I(0) = 0$ and $\omega = I(d\omega) + d(I\omega)$ for any form ω . It follows that $\omega = d(I\omega)$ if $d\omega = 0$. Let

$$\omega = \sum_{i_1 < \dots < i_l} \omega_{i_1, \dots, i_l} dx^{i_1} \wedge \dots \wedge dx^{i_l}.$$

Since A is star-shaped we can define

$$I\omega(x) = \sum_{i_1 < \dots < i_l} \sum_{\alpha=1}^l (-1)^{\alpha-1} \left(\int_0^1 t^{l-1} \omega_{i_1, \dots, i_l}(tx) dt \right) x^{i_\alpha} dx^{i_1} \wedge \dots \wedge \widehat{dx^{i_\alpha}} \wedge \dots \wedge dx^{i_l}.$$

(The symbol \wedge over dx^{i_α} indicates that it is omitted.) The

proof that $\omega = I(d\omega) + d(I\omega)$ is an elaborate computation: We have, using Problem 3-32,

$$\begin{aligned} d(I\omega) &= l \cdot \sum_{i_1 < \dots < i_l} \left(\int_0^1 t^{l-1} \omega_{i_1, \dots, i_l}(tx) dt \right) \\ &\quad dx^{i_1} \wedge \dots \wedge dx^{i_l} \\ &+ \sum_{i_1 < \dots < i_l} \sum_{\alpha=1}^l \sum_{j=1}^n (-1)^{\alpha-1} \left(\int_0^1 t^l D_j(\omega_{i_1, \dots, i_l})(tx) dt \right) x^{i_\alpha} \\ &\quad dx^j \wedge dx^{i_1} \wedge \dots \wedge \widehat{dx^{i_\alpha}} \wedge \dots \wedge dx^{i_l}. \end{aligned}$$

(Explain why we have the factor t^l , instead of t^{l-1} .) We also have

$$d\omega = \sum_{i_1 < \dots < i_l} \sum_{j=1}^n D_j(\omega_{i_1, \dots, i_l}) \cdot dx^j \wedge dx^{i_1} \wedge \dots \wedge dx^{i_l}.$$

Applying I to the $(l+1)$ -form $d\omega$, we obtain

$$\begin{aligned} I(d\omega) &= \sum_{i_1 < \dots < i_l} \sum_{j=1}^n \left(\int_0^1 t^l D_j(\omega_{i_1, \dots, i_l})(tx) dt \right) x^j \\ &\quad dx^{i_1} \wedge \dots \wedge dx^{i_l} \\ &- \sum_{i_1 < \dots < i_l} \sum_{j=1}^n \sum_{\alpha=1}^l (-1)^{\alpha-1} \left(\int_0^1 t^l D_j(\omega_{i_1, \dots, i_l})(tx) dt \right) x^{i_\alpha} \\ &\quad dx^j \wedge dx^{i_1} \wedge \dots \wedge \widehat{dx^{i_\alpha}} \wedge \dots \wedge dx^{i_l}. \end{aligned}$$

Adding, the triple sums cancel, and we obtain

$$\begin{aligned} d(I\omega) + I(d\omega) &= \sum_{i_1 < \dots < i_l} l \cdot \left(\int_0^1 t^{l-1} \omega_{i_1, \dots, i_l}(tx) dt \right) \\ &\quad dx^{i_1} \wedge \dots \wedge dx^{i_l} \\ &+ \sum_{i_1 < \dots < i_l} \sum_{j=1}^n \left(\int_0^1 t^l x^j D_j(\omega_{i_1, \dots, i_l})(tx) dt \right) \\ &\quad dx^{i_1} \wedge \dots \wedge dx^{i_l} \\ &= \sum_{i_1 < \dots < i_l} \left(\int_0^1 \frac{d}{dt} [t^l \omega_{i_1, \dots, i_l}(tx)] dt \right) \\ &\quad dx^{i_1} \wedge \dots \wedge dx^{i_l} \\ &= \sum_{i_1 < \dots < i_l} \omega_{i_1, \dots, i_l} dx^{i_1} \wedge \dots \wedge dx^{i_l} \\ &= \omega. \quad \blacksquare \end{aligned}$$

Problems. 4-13. (a) If $f: \mathbf{R}^n \rightarrow \mathbf{R}^m$ and $g: \mathbf{R}^m \rightarrow \mathbf{R}^p$, show that $(g \circ f)_* = g_* \circ f_*$ and $(g \circ f)^* = f^* \circ g^*$.

(b) If $f, g: \mathbf{R}^n \rightarrow \mathbf{R}$, show that $d(f \cdot g) = f \cdot dg + g \cdot df$.

4-14. Let c be a differentiable curve in \mathbf{R}^n , that is, a differentiable function $c: [0, 1] \rightarrow \mathbf{R}^n$. Define the **tangent vector** v of c at t as $c_*((e_1)_t) = ((c^1)'(t), \dots, (c^n)'(t))_{c(t)}$. If $f: \mathbf{R}^n \rightarrow \mathbf{R}^m$, show that the tangent vector to $f \circ c$ at t is $f_*(v)$.

4-15. Let $f: \mathbf{R} \rightarrow \mathbf{R}$ and define $c: \mathbf{R} \rightarrow \mathbf{R}^2$ by $c(t) = (t, f(t))$. Show that the end point of the tangent vector of c at t lies on the tangent line to the graph of f at $(t, f(t))$.

4-16. Let $c: [0, 1] \rightarrow \mathbf{R}^n$ be a curve such that $|c(t)| = 1$ for all t . Show that $c(t)_{c(t)}$ and the tangent vector to c at t are perpendicular.

4-17. If $f: \mathbf{R}^n \rightarrow \mathbf{R}^n$, define a vector field \mathbf{f} by $\mathbf{f}(p) = f(p)_p \in \mathbf{R}^n_p$.

(a) Show that every vector field F on \mathbf{R}^n is of the form \mathbf{f} for some f .

(b) Show that $\operatorname{div} \mathbf{f} = \operatorname{trace} f'$.

4-18. If $f: \mathbf{R}^n \rightarrow \mathbf{R}$, define a vector field $\operatorname{grad} f$ by

$$(\operatorname{grad} f)(p) = D_1 f(p) \cdot (e_1)_p + \dots + D_n f(p) \cdot (e_n)_p.$$

For obvious reasons we also write $\operatorname{grad} f = \nabla f$. If $\nabla f(p) = w_p$, prove that $D_v f(p) = \langle v, w \rangle$ and conclude that $\nabla f(p)$ is the direction in which f is changing fastest at p .

4-19. If F is a vector field on \mathbf{R}^3 , define the forms

$$\begin{aligned}\omega^1_F &= F^1 dx + F^2 dy + F^3 dz, \\ \omega^2_F &= F^1 dy \wedge dz + F^2 dz \wedge dx + F^3 dx \wedge dy.\end{aligned}$$

(a) Prove that

$$\begin{aligned}df &= \omega^1_{\operatorname{grad} f}, \\ d(\omega^1_F) &= \omega^2_{\operatorname{curl} F}, \\ d(\omega^2_F) &= (\operatorname{div} F) dx \wedge dy \wedge dz.\end{aligned}$$

(b) Use (a) to prove that

$$\begin{aligned}\operatorname{curl} \operatorname{grad} f &= 0, \\ \operatorname{div} \operatorname{curl} F &= 0.\end{aligned}$$

(c) If F is a vector field on a star-shaped open set A and $\operatorname{curl} F = 0$, show that $F = \operatorname{grad} f$ for some function $f: A \rightarrow \mathbf{R}$. Similarly, if $\operatorname{div} F = 0$, show that $F = \operatorname{curl} G$ for some vector field G on A .

4-20. Let $f: U \rightarrow \mathbf{R}^n$ be a differentiable function with a differentiable inverse $f^{-1}: f(U) \rightarrow \mathbf{R}^n$. If every closed form on U is exact, show that the same is true for $f(U)$. *Hint:* If $d\omega = 0$ and $f^*\omega = d\eta$, consider $(f^{-1})^*\eta$.

4-21.* Prove that on the set where θ is defined we have

$$d\theta = \frac{-y}{x^2 + y^2} dx + \frac{x}{x^2 + y^2} dy.$$

GEOMETRIC PRELIMINARIES

A **singular n -cube** in $A \subset \mathbf{R}^n$ is a continuous function $c: [0,1]^n \rightarrow A$ (here $[0,1]^n$ denotes the n -fold product $[0,1] \times \cdots \times [0,1]$). We let \mathbf{R}^0 and $[0,1]^0$ both denote $\{0\}$. A singular 0-cube in A is then a function $f: \{0\} \rightarrow A$ or, what amounts to the same thing, a point in A . A singular 1-cube is often called a **curve**. A particularly simple, but particularly important example of a singular n -cube in \mathbf{R}^n is the **standard n -cube** $I^n: [0,1]^n \rightarrow \mathbf{R}^n$ defined by $I^n(x) = x$ for $x \in [0,1]^n$.

We shall need to consider formal sums of singular n -cubes in A multiplied by integers, that is, expressions like

$$2c_1 + 3c_2 - 4c_3,$$

where c_1, c_2, c_3 are singular n -cubes in A . Such a finite sum of singular n -cubes with integer coefficients is called an **n -chain** in A . In particular a singular n -cube c is also considered as an n -chain $1 \cdot c$. It is clear how n -chains can be added, and multiplied by integers. For example

$$2(c_1 + 3c_4) + (-2)(c_1 + c_3 + c_2) = -2c_2 - 2c_3 + 6c_4.$$

(A rigorous exposition of this formalism is presented in Problem 4-22.)

For each singular n -chain c in A we shall define an $(n-1)$ -chain in A called the **boundary** of c and denoted ∂c . The boundary of I^2 , for example, might be defined as the sum of four singular 1-cubes arranged counterclockwise around the boundary of $[0,1]^2$, as indicated in Figure 4-4(a). It is actually much more convenient to define ∂I^2 as the sum, with the indicated coefficients, of the four singular 1-cubes shown in Figure 4-4(b). The precise definition of ∂I^n requires some preliminary notions. For each i with $1 \leq i \leq n$ we define two singular $(n-1)$ -cubes $I_{(i,0)}^n$ and $I_{(i,1)}^n$ as follows. If

FIGURE 4-4

$x \in [0,1]^{n-1}$, then

$$\begin{aligned} I_{(i,0)}^n(x) &= I^n(x^1, \dots, x^{i-1}, 0, x^i, \dots, x^{n-1}) \\ &= (x^1, \dots, x^{i-1}, 0, x^i, \dots, x^{n-1}), \\ I_{(i,1)}^n(x) &= I^n(x^1, \dots, x^{i-1}, 1, x^i, \dots, x^{n-1}) \\ &= (x^1, \dots, x^{i-1}, 1, x^i, \dots, x^{n-1}). \end{aligned}$$

We call $I_{(i,0)}^n$ the $(i,0)$ -face of I^n and $I_{(i,1)}^n$ the $(i,1)$ -face (Figure 4-5). We then define

$$\partial I^n = \sum_{i=1}^n \sum_{\alpha=0,1} (-1)^{i+\alpha} I_{(i,\alpha)}^n.$$

For a general singular n -cube $c: [0,1]^n \rightarrow A$ we first define the (i,α) -face,

$$c_{(i,\alpha)} = c \circ (I_{(i,\alpha)}^n)$$

and then define

$$\partial c = \sum_{i=1}^n \sum_{\alpha=0,1} (-1)^{i+\alpha} c_{(i,\alpha)}.$$

Finally we define the boundary of an n -chain $\sum a_i c_i$ by

$$\partial(\sum a_i c_i) = \sum a_i \partial(c_i).$$

Although these few definitions suffice for all applications in this book, we include here the one standard property of ∂ .

FIGURE 4-5

4-12 Theorem. If c is an n -chain in A , then $\partial(\partial c) = 0$. Briefly, $\partial^2 = 0$.

Proof. Let $i \leq j$ and consider $(I_{(i,\alpha)}^n)_{(j,\beta)}$. If $x \in [0,1]^{n-2}$, then, remembering the definition of the (j,β) -face of a singular n -cube, we have

$$\begin{aligned} (I_{(i,\alpha)}^n)_{(j,\beta)}(x) &= I_{(i,\alpha)}^n(I_{(j,\beta)}^{n-1}(x)) \\ &= I_{(i,\alpha)}^n(x^1, \dots, x^{j-1}, \beta, x^j, \dots, x^{n-2}) \\ &= I^n(x^1, \dots, x^{i-1}, \alpha, x^i, \dots, x^{j-1}, \beta, x^j, \dots, x^{n-2}). \end{aligned}$$

Similarly

$$\begin{aligned} (I_{(j+1,\beta)}^n)_{(i,\alpha)} &= I_{(j+1,\beta)}^n(I_{(i,\alpha)}^{n-1}(x)) \\ &= I_{(j+1,\beta)}^n(x^1, \dots, x^{i-1}, \alpha, x^i, \dots, x^{n-2}) \\ &= I^n(x^1, \dots, x^{i-1}, \alpha, x^i, \dots, x^{j-1}, \beta, x^j, \dots, x^{n-2}). \end{aligned}$$

Thus $(I_{(i,\alpha)}^n)_{(j,\beta)} = (I_{(j+1,\beta)}^n)_{(i,\alpha)}$ for $i \leq j$. (It may help to verify this in Figure 4-5.) It follows easily for any singular n -cube c that $(c_{(i,\alpha)})_{(j,\beta)} = (c_{(j+1,\beta)})_{(i,\alpha)}$ when $i \leq j$. Now

$$\begin{aligned} \partial(\partial c) &= \partial \left(\sum_{i=1}^n \sum_{\alpha=0,1} (-1)^{i+\alpha} c_{(i,\alpha)} \right) \\ &= \sum_{i=1}^n \sum_{\alpha=0,1} \sum_{j=1}^{n-1} \sum_{\beta=0,1} (-1)^{i+\alpha+j+\beta} (c_{(i,\alpha)})_{(j,\beta)}. \end{aligned}$$

In this sum $(c_{(i,\alpha)})_{(j,\beta)}$ and $(c_{(j+1,\beta)})_{(i,\alpha)}$ occur with opposite signs. Therefore all terms cancel out in pairs and $\partial(\partial c) = 0$. Since the theorem is true for any singular n -cube, it is also true for singular n -chains. ■

It is natural to ask whether Theorem 4-12 has a converse: If $\partial c = 0$, is there a chain d in A such that $c = \partial d$? The answer depends on A and is generally "no." For example, define $c: [0,1] \rightarrow \mathbb{R}^2 - 0$ by $c(t) = (\sin 2\pi nt, \cos 2\pi nt)$, where n is a non-zero integer. Then $c(1) = c(0)$, so $\partial c = 0$. But (Problem 4-26) there is no 2-chain c' in $\mathbb{R}^2 - 0$, with $\partial c' = c$.

Problems. 4-22. Let \mathcal{S} be the set of all singular n -cubes, and \mathbb{Z} the integers. An n -chain is a function $f: \mathcal{S} \rightarrow \mathbb{Z}$ such that $f(c) = 0$ for all but finitely many c . Define $f + g$ and nf by $(f + g)(c) = f(c) + g(c)$ and $nf(c) = n \cdot f(c)$. Show that $f + g$ and nf are n -chains if f and g are. If $c \in \mathcal{S}$, let c also denote the function f such that $f(c) = 1$ and $f(c') = 0$ for $c' \neq c$. Show that every n -chain f can be written $a_1 c_1 + \cdots + a_k c_k$ for some integers a_1, \dots, a_k and singular n -cubes c_1, \dots, c_k .

4-23. For $R > 0$ and n an integer, define the singular 1-cube $c_{R,n}: [0,1] \rightarrow \mathbb{R}^2 - 0$ by $c_{R,n}(t) = (R \cos 2\pi nt, R \sin 2\pi nt)$. Show that there is a singular 2-cube $c: [0,1]^2 \rightarrow \mathbb{R}^2 - 0$ such that $c_{R_1,n} - c_{R_2,n} = \partial c$.

4-24. If c is a singular 1-cube in $\mathbb{R}^2 - 0$ with $c(0) = c(1)$, show that there is an integer n such that $c - c_{1,n} = \partial c^2$ for some 2-chain c^2 . *Hint:* First partition $[0,1]$ so that each $c([t_{i-1}, t_i])$ is contained on one side of some line through 0.

THE FUNDAMENTAL THEOREM OF CALCULUS

The fact that $d^2 = 0$ and $\partial^2 = 0$, not to mention the typographical similarity of d and ∂ , suggests some connection between chains and forms. This connection is established by integrating forms over chains. Henceforth only differentiable singular n -cubes will be considered.

If ω is a k -form on $[0,1]^k$, then $\omega = f dx^1 \wedge \cdots \wedge dx^k$ for a unique function f . We define

$$\int_{[0,1]^k} \omega = \int_{[0,1]^k} f.$$

We could also write this as

$$\int_{[0,1]^k} f dx^1 \wedge \cdots \wedge dx^k = \int_{[0,1]^k} f(x^1, \dots, x^k) dx^1 \cdots dx^k,$$

one of the reasons for introducing the functions x^i .

If ω is a k -form on A and c is a singular k -cube in A , we define

$$\int_c \omega = \int_{[0,1]^k} c^* \omega.$$

Note, in particular, that

$$\begin{aligned} \int_{I^k} f dx^1 \wedge \cdots \wedge dx^k &= \int_{[0,1]^k} (I^k)^*(f dx^1 \wedge \cdots \wedge dx^k) \\ &= \int_{[0,1]^k} f(x^1, \dots, x^k) dx^1 \cdots dx^k. \end{aligned}$$

A special definition must be made for $k = 0$. A 0-form ω is a function; if $c: \{0\} \rightarrow A$ is a singular 0-cube in A we define

$$\int_c \omega = \omega(c(0)).$$

The integral of ω over a k -chain $c = \sum a_i c_i$ is defined by

$$\int_c \omega = \sum a_i \int_{c_i} \omega.$$

The integral of a 1-form over a 1-chain is often called a **line integral**. If $P dx + Q dy$ is a 1-form on \mathbf{R}^2 and $c: [0,1] \rightarrow \mathbf{R}^2$ is a singular 1-cube (a curve), then one can (but we will not) prove that

$$\begin{aligned} \int_c P dx + Q dy &= \lim \sum_{i=1}^n [c^1(t_i) - c^1(t_{i-1})] \cdot P(c(t_i)) \\ &\quad + [c^2(t_i) - c^2(t_{i-1})] \cdot Q(c(t_i)) \end{aligned}$$

where t_0, \dots, t_n is a partition of $[0,1]$, the choice of t^i in $[t_{i-1}, t_i]$ is arbitrary, and the limit is taken over all partitions

as the maximum of $|t_i - t_{i-1}|$ goes to 0. The right side is often taken as a definition of $\int_c P dx + Q dy$. This is a natural definition to make, since these sums are very much like the sums appearing in the definition of ordinary integrals. However such an expression is almost impossible to work with and is quickly equated with an integral equivalent to $\int_{[0,1]} c^*(P dx + Q dy)$. Analogous definitions for **surface integrals**, that is, integrals of 2-forms over singular 2-cubes, are even more complicated and difficult to use. This is one reason why we have avoided such an approach. The other reason is that the definition given here is the one that makes sense in the more general situations considered in Chapter 5.

The relationship between forms, chains, d , and ∂ is summed up in the neatest possible way by Stokes' theorem, sometimes called the fundamental theorem of calculus in higher dimensions (if $k = 1$ and $c = I^1$, it really is the fundamental theorem of calculus).

4-13 Theorem (Stokes' Theorem). *If ω is a $(k - 1)$ -form on an open set $A \subset \mathbf{R}^n$ and c is a k -chain in A , then*

$$\int_c d\omega = \int_{\partial c} \omega.$$

Proof. Suppose first that $c = I^k$ and ω is a $(k - 1)$ -form on $[0, 1]^k$. Then ω is the sum of $(k - 1)$ -forms of the type

$$f dx^1 \wedge \cdots \wedge \widehat{dx^i} \wedge \cdots \wedge dx^k,$$

and it suffices to prove the theorem for each of these. This simply involves a computation:

Note that

$$\begin{aligned} & \int_{[0,1]^{k-1}} I_{(j,\alpha)}^k (f dx^1 \wedge \cdots \wedge \widehat{dx^i} \wedge \cdots \wedge dx^k) \\ &= \begin{cases} 0 & \text{if } j \neq i, \\ \int_{[0,1]^k} f(x^1, \dots, \alpha, \dots, x^k) dx^1 \cdots dx^k & \text{if } j = i. \end{cases} \end{aligned}$$

Therefore

$$\begin{aligned}
& \int_{\partial I^k} f dx^1 \wedge \cdots \wedge \widehat{dx^i} \wedge \cdots \wedge dx^k \\
&= \sum_{j=1}^k \sum_{\alpha=0,1} (-1)^{j+\alpha} \int_{[0,1]^{k-1}} I_{(j,\alpha)}^k * (f dx^1 \wedge \cdots \wedge \widehat{dx^i} \\
&\quad \wedge \cdots \wedge dx^k) \\
&= (-1)^{i+1} \int_{[0,1]^k} f(x^1, \dots, 1, \dots, x^k) dx^1 \cdots dx^k \\
&\quad + (-1)^i \int_{[0,1]^k} f(x^1, \dots, 0, \dots, x^k) dx^1 \cdots dx^k.
\end{aligned}$$

On the other hand,

$$\begin{aligned}
& \int_{I^k} d(f dx^1 \wedge \cdots \wedge \widehat{dx^i} \wedge \cdots \wedge dx^k) \\
&= \int_{[0,1]^k} D_i f dx^i \wedge dx^1 \wedge \cdots \wedge \widehat{dx^i} \wedge \cdots \wedge dx^k \\
&= (-1)^{i-1} \int_{[0,1]^k} D_i f.
\end{aligned}$$

By Fubini's theorem and the fundamental theorem of calculus (in one dimension) we have

$$\begin{aligned}
& \int_{I^k} d(f dx^1 \wedge \cdots \wedge \widehat{dx^i} \wedge \cdots \wedge dx^k) \\
&= (-1)^{i-1} \int_0^1 \cdots \left(\int_0^1 D_i f(x^1, \dots, x^k) dx^i \right) dx^1 \cdots \\
&\quad \widehat{dx^i} \cdots dx^k \\
&= (-1)^{i-1} \int_0^1 \cdots \int_0^1 [f(x^1, \dots, 1, \dots, x^k) \\
&\quad - f(x^1, \dots, 0, \dots, x^k)] dx^1 \cdots \widehat{dx^i} \cdots dx^k \\
&= (-1)^{i-1} \int_{[0,1]^k} f(x^1, \dots, 1, \dots, x^k) dx^1 \cdots dx^k \\
&\quad + (-1)^i \int_{[0,1]^k} f(x^1, \dots, 0, \dots, x^k) dx^1 \cdots dx^k.
\end{aligned}$$

Thus

$$\int_{I^k} d\omega = \int_{\partial I^k} \omega.$$

If c is an arbitrary singular k -cube, working through the definitions will show that

$$\int_{\partial c} \omega = \int_{\partial I^k} c^* \omega.$$

Therefore

$$\int_c d\omega = \int_{I^k} c^*(d\omega) = \int_{I^k} d(c^*\omega) = \int_{\partial I^k} c^*\omega = \int_{\partial c} \omega.$$

Finally, if c is a k -chain $\sum a_i c_i$, we have

$$\int_c d\omega = \sum a_i \int_{c_i} d\omega = \sum a_i \int_{\partial c_i} \omega = \int_{\partial c} \omega. \blacksquare$$

Stokes' theorem shares three important attributes with many fully evolved major theorems:

1. It is trivial.
2. It is trivial because the terms appearing in it have been properly defined.
3. It has significant consequences.

Since this entire chapter was little more than a series of definitions which made the statement and proof of Stokes' theorem possible, the reader should be willing to grant the first two of these attributes to Stokes' theorem. The rest of the book is devoted to justifying the third.

Problems. 4-25. (*Independence of parameterization*). Let c be a singular k -cube and $p: [0,1]^k \rightarrow [0,1]^k$ a 1-1 function such that $p([0,1]^k) = [0,1]^k$ and $\det p'(x) \geq 0$ for $x \in [0,1]^k$. If ω is a k -form, show that

$$\int_c \omega = \int_{c \circ p} \omega.$$

- 4-26. Show that $\int_{c_{R,n}} d\theta = 2\pi n$, and use Stokes' theorem to conclude that $c_{R,n} \neq \partial c$ for any 2-chain c in $\mathbf{R}^2 - 0$ (recall the definition of $c_{R,n}$ in Problem 4-23).
- 4-27. Show that the integer n of Problem 4-24 is unique. This integer is called the **winding number** of c around 0.
- 4-28. Recall that the set of complex numbers \mathbf{C} is simply \mathbf{R}^2 with $(a,b) = a + bi$. If $a_1, \dots, a_n \in \mathbf{C}$ let $f: \mathbf{C} \rightarrow \mathbf{C}$ be $f(z) = z^n + a_1 z^{n-1} + \dots + a_n$. Define the singular 1-cube $c_{R,f}$:

$[0,1] \rightarrow \mathbf{C} - 0$ by $c_{R,f} = f \circ c_{R,1}$, and the singular 2-cube c by $c(s,t) = t \cdot c_{R,n}(s) + (1-t)c_{R,f}(s)$.

(a) Show that $\partial c = c_{R,f} - c_{R,n}$, and that $c([0,1] \times [0,1]) \subset \mathbf{C} - 0$ if R is large enough.

(b) Using Problem 4-26, prove the *Fundamental Theorem of Algebra*: Every polynomial $z^n + a_1 z^{n-1} + \cdots + a_n$ with $a_i \in \mathbf{C}$ has a root in \mathbf{C} .

4-29. If ω is a 1-form $f dx$ on $[0,1]$ with $f(0) = f(1)$, show that there is a unique number λ such that $\omega - \lambda dx = dg$ for some function g with $g(0) = g(1)$. *Hint*: Integrate $\omega - \lambda dx = dg$ on $[0,1]$ to find λ .

4-30. If ω is a 1-form on $\mathbf{R}^2 - 0$ such that $d\omega = 0$, prove that

$$\omega = \lambda d\theta + dg$$

for some $\lambda \in \mathbf{R}$ and $g: \mathbf{R}^2 - 0 \rightarrow \mathbf{R}$. *Hint*: If

$$c_{R,1}^*(\omega) = \lambda_R dx + d(g_R),$$

show that all numbers λ_R have the same value λ .

4-31. If $\omega \neq 0$, show that there is a chain c such that $\int_c \omega \neq 0$. Use this fact, Stokes' theorem and $\partial^2 = 0$ to prove $d^2 = 0$.

4-32. (a) Let c_1, c_2 be singular 1-cubes in \mathbf{R}^2 with $c_1(0) = c_2(0)$ and $c_1(1) = c_2(1)$. Show that there is a singular 2-cube c such that $\partial c = c_1 - c_2 + c_3 - c_4$, where c_3 and c_4 are *degenerate*, that is, $c_3([0,1])$ and $c_4([0,1])$ are points. Conclude that $\int_{c_1} \omega = \int_{c_2} \omega$ if ω is exact. Give a counterexample on $\mathbf{R}^2 - 0$ if ω is merely closed.

(b) If ω is a 1-form on a subset of \mathbf{R}^2 and $\int_{c_1} \omega = \int_{c_2} \omega$ for all c_1, c_2 with $c_1(0) = c_2(0)$ and $c_1(1) = c_2(1)$, show that ω is exact. *Hint*: Consider Problems 2-21 and 3-34.

4-33. (*A first course in complex variables.*) If $f: \mathbf{C} \rightarrow \mathbf{C}$, define f to be **differentiable** at $z_0 \in \mathbf{C}$ if the limit

$$f'(z_0) = \lim_{z \rightarrow z_0} \frac{f(z) - f(z_0)}{z - z_0}$$

exists. (This quotient involves two complex numbers and this definition is completely different from the one in Chapter 2.) If f is differentiable at every point z in an open set A and f' is continuous on A , then f is called **analytic** on A .

(a) Show that $f(z) = z$ is analytic and $f(z) = \bar{z}$ is not (where $\overline{x + iy} = x - iy$). Show that the sum, product, and quotient of analytic functions are analytic.

(b) If $f = u + iv$ is analytic on A , show that u and v satisfy the *Cauchy-Riemann equations*:

$$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y} \quad \text{and} \quad \frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x}.$$

Hint: Use the fact that $\lim_{z \rightarrow z_0} [f(z) - f(z_0)]/(z - z_0)$ must be the same for $z = z_0 + (x + i \cdot 0)$ and $z = z_0 + (0 + i \cdot y)$ with $x, y \rightarrow 0$. (The converse is also true, if u and v are continuously differentiable; this is more difficult to prove.)

(c) Let $T: \mathbf{C} \rightarrow \mathbf{C}$ be a linear transformation (where \mathbf{C} is considered as a vector space over \mathbf{R}). If the matrix of T with respect to the basis $(1, i)$ is $\begin{pmatrix} a, b \\ c, d \end{pmatrix}$ show that T is multiplication by a complex number if and only if $a = d$ and $b = -c$. Part (b) shows that an analytic function $f: \mathbf{C} \rightarrow \mathbf{C}$, considered as a function $f: \mathbf{R}^2 \rightarrow \mathbf{R}^2$, has a derivative $Df(z_0)$ which is multiplication by a complex number. What complex number is this?

(d) Define

$$\begin{aligned} d(\omega + i\eta) &= d\omega + i d\eta, \\ \int_c \omega + i\eta &= \int_c \omega + i \int_c \eta, \end{aligned}$$

$$(\omega + i\eta) \wedge (\theta + i\lambda) = \omega \wedge \theta - \eta \wedge \lambda + i(\eta \wedge \theta + \omega \wedge \lambda),$$

and

$$dz = dx + i dy.$$

Show that $d(f \cdot dz) = 0$ if and only if f satisfies the Cauchy-Riemann equations.

(e) Prove the *Cauchy Integral Theorem*: If f is analytic on A , then $\int_c f dz = 0$ for every closed curve c (singular 1-cube with $c(0) = c(1)$) such that $c = \partial c'$ for some 2-chain c' in A .

(f) Show that if $g(z) = 1/z$, then $g \cdot dz$ [or $(1/z)dz$ in classical notation] equals $i d\theta + dh$ for some function $h: \mathbf{C} - 0 \rightarrow \mathbf{R}$. Conclude that $\int_{c_{R,n}} (1/z) dz = 2\pi i n$.

(g) If f is analytic on $\{z: |z| < 1\}$, use the fact that $g(z) = f(z)/z$ is analytic in $\{z: 0 < |z| < 1\}$ to show that

$$\int_{c_{R_1,n}} \frac{f(z)}{z} dz = \int_{c_{R_2,n}} \frac{f(z)}{z} dz$$

if $0 < R_1, R_2 < 1$. Use (f) to evaluate $\lim_{R \rightarrow 0} \int_{c_{R,n}} f(z)/z dz$ and conclude:

Cauchy Integral Formula: If f is analytic on $\{z: |z| < 1\}$ and c is a closed curve in $\{z: 0 < |z| < 1\}$ with winding number n around 0, then

$$n \cdot f(0) = \frac{1}{2\pi i} \int_c \frac{f(z)}{z} dz.$$

FIGURE 4-6

4-34. If $F: [0, 1]^2 \rightarrow \mathbf{R}^3$ and $s \in [0, 1]$ define $F_s: [0, 1] \rightarrow \mathbf{R}^3$ by $F_s(t) = F(s, t)$. If each F_s is a closed curve, F is called a **homotopy** between the closed curve F_0 and the closed curve F_1 . Suppose F and G are homotopies of closed curves; if for each s the closed curves F_s and G_s do not intersect, the pair (F, G) is called a homotopy between the nonintersecting closed curves F_0, G_0 and F_1, G_1 . It is intuitively obvious that there is no such homotopy with F_0, G_0 the pair of curves shown in Figure 4-6 (a), and F_1, G_1 the pair of (b) or (c). The present problem, and Problem 5-33 prove this for (b) but the proof for (c) requires different techniques.

(a) If $f, g: [0, 1] \rightarrow \mathbf{R}^3$ are nonintersecting closed curves define $c_{f,g}: [0, 1]^2 \rightarrow \mathbf{R}^3 - 0$ by

$$c_{f,g}(u, v) = f(u) - g(v).$$

If (F, G) is a homotopy of nonintersecting closed curves define $C_{F,G}: [0, 1]^3 \rightarrow \mathbf{R}^3 - 0$ by

$$C_{F,G}(s, u, v) = c_{F_s, G_s}(u, v) = F(s, u) - G(s, v).$$

Show that

$$\partial C_{F,G} = c_{F_0, G_0} - c_{F_1, G_1}.$$

(b) If ω is a closed 2-form on $\mathbf{R}^3 - 0$ show that

$$\int_{c_{F_0, G_0}} \omega = \int_{c_{F_1, G_1}} \omega.$$

Integration on Manifolds

MANIFOLDS

If U and V are open sets in \mathbf{R}^n , a differentiable function $h: U \rightarrow V$ with a differentiable inverse $h^{-1}: V \rightarrow U$ will be called a **diffeomorphism**. (“Differentiable” henceforth means “ C^∞ ”.)

A subset M of \mathbf{R}^n is called a **k -dimensional manifold** (in \mathbf{R}^n) if for every point $x \in M$ the following condition is satisfied:

(M) There is an open set U containing x , an open set $V \subset \mathbf{R}^n$, and a diffeomorphism $h: U \rightarrow V$ such that

$$\begin{aligned} h(U \cap M) &= V \cap (\mathbf{R}^k \times \{0\}) \\ &= \{y \in V: y^{k+1} = \cdots = y^n = 0\}. \end{aligned}$$

In other words, $U \cap M$ is, “up to diffeomorphism,” simply $\mathbf{R}^k \times \{0\}$ (see Figure 5-1). The two extreme cases of our definition should be noted: a point in \mathbf{R}^n is a 0-dimensional manifold, and an open subset of \mathbf{R}^n is an n -dimensional manifold.

One common example of an n -dimensional manifold is the

FIGURE 5-1. A one-dimensional manifold in \mathbb{R}^2 and a two-dimensional manifold in \mathbb{R}^3 .

n -sphere S^n , defined as $\{x \in \mathbf{R}^{n+1}: |x| = 1\}$. We leave it as an exercise for the reader to prove that condition (M) is satisfied. If you are unwilling to trouble yourself with the details, you may instead use the following theorem, which provides many examples of manifolds (note that $S^n = g^{-1}(0)$, where $g: \mathbf{R}^{n+1} \rightarrow \mathbf{R}$ is defined by $g(x) = |x|^2 - 1$).

5-1 Theorem. *Let $A \subset \mathbf{R}^n$ be open and let $g: A \rightarrow \mathbf{R}^p$ be a differentiable function such that $g'(x)$ has rank p whenever $g(x) = 0$. Then $g^{-1}(0)$ is an $(n - p)$ -dimensional manifold in \mathbf{R}^n .*

Proof. This follows immediately from Theorem 2-13. ■

There is an alternative characterization of manifolds which is very important.

5-2 Theorem. *A subset M of \mathbf{R}^n is a k -dimensional manifold if and only if for each point $x \in M$ the following “coordinate condition” is satisfied:*

(C) *There is an open set U containing x , an open set $W \subset \mathbf{R}^k$, and a 1-1 differentiable function $f: W \rightarrow \mathbf{R}^n$ such that*

- (1) $f(W) = M \cap U$,
- (2) $f'(y)$ has rank k for each $y \in W$,
- (3) $f^{-1}: f(W) \rightarrow W$ is continuous.

[Such a function f is called a **coordinate system** around x (see Figure 5-2).]

Proof. If M is a k -dimensional manifold in \mathbf{R}^n , choose $h: U \rightarrow V$ satisfying (M). Let $W = \{a \in \mathbf{R}^k: (a, 0) \in h(M)\}$ and define $f: W \rightarrow \mathbf{R}^n$ by $f(a) = h^{-1}(a, 0)$. Clearly $f(W) = M \cap U$ and f^{-1} is continuous. If $H: U \rightarrow \mathbf{R}^k$ is $H(z) = (h^1(z), \dots, h^k(z))$, then $H(f(y)) = y$ for all $y \in W$; therefore $H'(f(y)) \cdot f'(y) = I$ and $f'(y)$ must have rank k .

Suppose, conversely, that $f: W \rightarrow \mathbf{R}^n$ satisfies condition (C). Let $x = f(y)$. Assume that the matrix $(D_j f^i(y))$, $1 \leq i, j \leq k$ has a non-zero determinant. Define $g: W \times \mathbf{R}^{n-k} \rightarrow \mathbf{R}^n$ by

FIGURE 5-2

$g(a,b) = f(a) + (0,b)$. Then $\det g'(a,b) = \det (D_j f^i(a))$, so $\det g'(y,0) \neq 0$. By Theorem 2-11 there is an open set V_1' containing $(y,0)$ and an open set V_2' containing $g(y,0) = x$ such that $g: V_1' \rightarrow V_2'$ has a differentiable inverse $h: V_2' \rightarrow V_1'$. Since f^{-1} is continuous, $\{f(a): (a,0) \in V_1'\} = U \cap f(W)$ for some open set U . Let $V_2 = V_2' \cap U$ and $V_1 = g^{-1}(V_2)$. Then $V_2 \cap M$ is exactly $\{f(a): (a,0) \in V_1\} = \{g(a,0): (a,0) \in V_1\}$, so

$$\begin{aligned} h(V_2 \cap M) &= g^{-1}(V_2 \cap M) = g^{-1}(\{g(a,0): (a,0) \in V_1\}) \\ &= V_1 \cap (\mathbf{R}^k \times \{0\}). \quad \blacksquare \end{aligned}$$

One consequence of the proof of Theorem 5-2 should be noted. If $f_1: W_1 \rightarrow \mathbf{R}^n$ and $f_2: W_2 \rightarrow \mathbf{R}^n$ are two coordinate

systems, then

$$f_2^{-1} \circ f_1: f_1^{-1}(f_2(W_2)) \rightarrow \mathbf{R}^k$$

is differentiable with non-singular Jacobian. In fact, $f_2^{-1}(y)$ consists of the first k components of $h(y)$.

The **half-space** $\mathbf{H}^k \subset \mathbf{R}^k$ is defined as $\{x \in \mathbf{R}^k: x^k \geq 0\}$. A subset M of \mathbf{R}^n is a **k -dimensional manifold-with-boundary** (Figure 5-3) if for every point $x \in M$ either condition (M) or the following condition is satisfied:

(M') There is an open set U containing x , an open set $V \subset \mathbf{R}^n$, and a diffeomorphism $h: U \rightarrow V$ such that

$$\begin{aligned} h(U \cap M) &= V \cap (\mathbf{H}^k \times \{0\}) \\ &= \{y \in V: y^k \geq 0 \text{ and } y^{k+1} = \dots = y^n = 0\} \end{aligned}$$

and $h(x)$ has k th component $= 0$.

It is important to note that conditions (M) and (M') cannot both hold for the same x . In fact, if $h_1: U_1 \rightarrow V_1$ and $h_2: U_2 \rightarrow V_2$ satisfied (M) and (M'), respectively, then $h_2 \circ h_1^{-1}$ would be a differentiable map that takes an open set in \mathbf{R}^k , containing $h(x)$, into a subset of \mathbf{H}^k which is not open in \mathbf{R}^k . Since $\det(h_2 \circ h_1^{-1})' \neq 0$, this contradicts Problem 2-36. The set of all points $x \in M$ for which condition M' is satisfied is called the **boundary** of M and denoted ∂M . This

FIGURE 5-3. A one-dimensional and a two-dimensional manifold-with-boundary in \mathbf{R}^3 .

must not be confused with the boundary of a set, as defined in Chapter 1 (see Problems 5-3 and 5-8).

Problems. 5-1. If M is a k -dimensional manifold-with-boundary, prove that ∂M is a $(k - 1)$ -dimensional manifold and $M - \partial M$ is a k -dimensional manifold.

5-2. Find a counterexample to Theorem 5-2 if condition (3) is omitted.

Hint: Wrap an open interval into a figure six.

5-3. (a) Let $A \subset \mathbf{R}^n$ be an open set such that boundary A is an $(n - 1)$ -dimensional manifold. Show that $N = A \cup \text{boundary } A$ is an n -dimensional manifold-with-boundary. (It is well to bear in mind the following example: if $A = \{x \in \mathbf{R}^n: |x| < 1 \text{ or } 1 < |x| < 2\}$ then $N = A \cup \text{boundary } A$ is a manifold-with-boundary, but $\partial N \neq \text{boundary } A$.)

(b) Prove a similar assertion for an open subset of an n -dimensional manifold.

5-4. Prove a partial converse of Theorem 5-1: If $M \subset \mathbf{R}^n$ is a k -dimensional manifold and $x \in M$, then there is an open set $A \subset \mathbf{R}^n$ containing x and a differentiable function $g: A \rightarrow \mathbf{R}^{n-k}$ such that $A \cap M = g^{-1}(0)$ and $g'(y)$ has rank $n - k$ when $g(y) = 0$.

5-5. Prove that a k -dimensional (vector) subspace of \mathbf{R}^n is a k -dimensional manifold.

FIGURE 5-4

- 5-6. If $f: \mathbf{R}^n \rightarrow \mathbf{R}^m$, the **graph** of f is $\{(x, y): y = f(x)\}$. Show that the graph of f is an n -dimensional manifold if and only if f is differentiable.
- 5-7. Let $\mathbf{K}^n = \{x \in \mathbf{R}^n: x^1 = 0 \text{ and } x^2, \dots, x^{n-1} > 0\}$. If $M \subset \mathbf{K}^n$ is a k -dimensional manifold and N is obtained by revolving M around the axis $x^1 = \dots = x^{n-1} = 0$, show that N is a $(k + 1)$ -dimensional manifold. **Example: the torus (Figure 5-4).**
- 5-8. (a) If M is a k -dimensional manifold in \mathbf{R}^n and $k < n$, show that M has measure 0.
- (b) If M is a closed n -dimensional manifold-with-boundary in \mathbf{R}^n , show that the boundary of M is ∂M . Give a counterexample if M is not closed.
- (c) If M is a compact n -dimensional manifold-with-boundary in \mathbf{R}^n , show that M is Jordan-measurable.

FIELDS AND FORMS ON MANIFOLDS

Let M be a k -dimensional manifold in \mathbf{R}^n and let $f: W \rightarrow \mathbf{R}^n$ be a coordinate system around $x = f(a)$. Since $f'(a)$ has rank k , the linear transformation $f_*: \mathbf{R}^k_a \rightarrow \mathbf{R}^n_x$ is 1-1, and $f_*(\mathbf{R}^k_a)$ is a k -dimensional subspace of \mathbf{R}^n_x . If $g: V \rightarrow \mathbf{R}^n$ is another coordinate system, with $x = g(b)$, then

$$g_*(\mathbf{R}^k_b) = f_*(f^{-1} \circ g)_*(\mathbf{R}^k_b) = f_*(\mathbf{R}^k_a).$$

Thus the k -dimensional subspace $f_*(\mathbf{R}^k_a)$ does not depend on the coordinate system f . This subspace is denoted M_x , and is called the **tangent space** of M at x (see Figure 5-5). In later sections we will use the fact that there is a natural inner product T_x on M_x , induced by that on \mathbf{R}^n_x : if $v, w \in M_x$ define $T_x(v, w) = \langle v, w \rangle_x$.

Suppose that A is an open set containing M , and F is a differentiable vector field on A such that $F(x) \in M_x$ for each $x \in M$. If $f: W \rightarrow \mathbf{R}^n$ is a coordinate system, there is a unique (differentiable) vector field G on W such that $f_*(G(a)) = F(f(a))$ for each $a \in W$. We can also consider a function F which merely assigns a vector $F(x) \in M_x$ for each $x \in M$; such a function is called a **vector field on M** . There is still a unique vector field G on W such that $f_*(G(a)) = F(f(a))$ for $a \in W$; we *define* F to be differentiable if G is differentiable. Note that our definition does not depend on the coordinate

FIGURE 5-5

system chosen: if $g: V \rightarrow \mathbf{R}^n$ and $g_*(H(b)) = F(g(b))$ for all $b \in V$, then the component functions of $H(b)$ must equal the component functions of $G(f^{-1}(g(b)))$, so H is differentiable if G is.

Precisely the same considerations hold for forms. A function ω which assigns $\omega(x) \in \Lambda^p(M_x)$ for each $x \in M$ is called a **p -form on M** . If $f: W \rightarrow \mathbf{R}^n$ is a coordinate system, then $f^*\omega$ is a p -form on W ; we *define* ω to be differentiable if $f^*\omega$ is. A p -form ω on M can be written as

$$\omega = \sum_{i_1 < \cdots < i_p} \omega_{i_1, \dots, i_p} dx^{i_1} \wedge \cdots \wedge dx^{i_p}.$$

Here the functions ω_{i_1, \dots, i_p} are defined only on M . The definition of $d\omega$ given previously would make no sense here, since $D_j(\omega_{i_1, \dots, i_p})$ has no meaning. Nevertheless, there is a reasonable way of defining $d\omega$.

5-3 Theorem. *There is a unique $(p + 1)$ -form $d\omega$ on M such that for every coordinate system $f: W \rightarrow \mathbf{R}^n$ we have*

$$f^*(d\omega) = d(f^*\omega).$$

Proof. If $f: W \rightarrow \mathbf{R}^n$ is a coordinate system with $x = f(a)$ and $v_1, \dots, v_{p+1} \in M_x$, there are unique w_1, \dots, w_{p+1} in \mathbf{R}^k_a such that $f_*(w_i) = v_i$. Define $d\omega(x)(v_1, \dots, v_{p+1}) = d(f^*\omega)(a)(w_1, \dots, w_{p+1})$. One can check that this definition of $d\omega(x)$ does not depend on the coordinate system f , so that $d\omega$ is well-defined. Moreover, it is clear that $d\omega$ has to be defined this way, so $d\omega$ is unique. ■

It is often necessary to choose an orientation μ_x for each tangent space M_x of a manifold M . Such choices are called **consistent** (Figure 5-6) provided that for every coordinate

FIGURE 5-6. (a) Consistent and (b) inconsistent choices of orientations.

system $f: W \rightarrow \mathbf{R}^n$ and $a, b \in W$ the relation

$$[f_*((e_1)_a), \dots, f_*((e_k)_a)] = \mu_{f(a)}$$

holds if and only if

$$[f_*((e_1)_b), \dots, f_*((e_k)_b)] = \mu_{f(b)}.$$

Suppose orientations μ_x have been chosen consistently. If $f: W \rightarrow \mathbf{R}^n$ is a coordinate system such that

$$[f_*((e_1)_a), \dots, f_*((e_k)_a)] = \mu_{f(a)}$$

for one, and hence for every $a \in W$, then f is called **orientation-preserving**. If f is *not* orientation-preserving and $T: \mathbf{R}^k \rightarrow \mathbf{R}^k$ is a linear transformation with $\det T = -1$, then $f \circ T$ is orientation-preserving. Therefore there is an orientation-preserving coordinate system around each point. If f and g are orientation-preserving and $x = f(a) = g(b)$, then the relation

$$[f_*((e_1)_a), \dots, f_*((e_k)_a)] = \mu_x = [g_*((e_1)_b), \dots, g_*((e_k)_b)]$$

FIGURE 5-7. The Möbius strip, a non-orientable manifold. A basis begins at P , moves to the right and around, and comes back to P with the wrong orientation.

implies that

$$[(g^{-1} \circ f)_*((e_1)_a), \dots, (g^{-1} \circ f)_*((e_k)_a)] = [(e_1)_b, \dots, (e_k)_b],$$

so that $\det (g^{-1} \circ f)' > 0$, an important fact to remember.

A manifold for which orientations μ_x can be chosen consistently is called **orientable**, and a particular choice of the μ_x is called an **orientation** μ of M . A manifold together with an orientation μ is called an **oriented** manifold. The classical example of a non-orientable manifold is the Möbius strip. A model can be made by gluing together the ends of a strip of paper which has been given a half twist (Figure 5-7).

Our definitions of vector fields, forms, and orientations can be made for manifolds-with-boundary also. If M is a k -dimensional manifold-with-boundary and $x \in \partial M$, then $(\partial M)_x$ is a $(k - 1)$ -dimensional subspace of the k -dimensional vector space M_x . Thus there are exactly two unit vectors in M_x which are perpendicular to $(\partial M)_x$; they can be distinguished as follows (Figure 5-8). If $f: W \rightarrow \mathbf{R}^n$ is a coordinate system with $W \subset H^k$ and $f(0) = x$, then only one of these unit vectors is $f_*(v_0)$ for some v_0 with $v^k < 0$. This unit vector is called the **outward unit normal** $n(x)$; it is not hard to check that this definition does not depend on the coordinate system f .

Suppose that μ is an orientation of a k -dimensional manifold-with-boundary M . If $x \in \partial M$, choose $v_1, \dots, v_{k-1} \in (\partial M)_x$ so that $[n(x), v_1, \dots, v_{k-1}] = \mu_x$. If it is also true that $[n(x), w_1, \dots, w_{k-1}] = \mu_x$, then both $[v_1, \dots, v_{k-1}]$ and $[w_1, \dots, w_{k-1}]$ are the same orientation for $(\partial M)_x$. This orientation is denoted $(\partial\mu)_x$. It is easy to see that the orientations $(\partial\mu)_x$, for $x \in \partial M$, are consistent on ∂M . Thus if M is orientable, ∂M is also orientable, and an orientation μ for M determines an orientation $\partial\mu$ for ∂M , called the **induced orientation**. If we apply these definitions to \mathbf{H}^k with the usual orientation, we find that the induced orientation on $\mathbf{R}^{k-1} = \{x \in \mathbf{H}^k: x^k = 0\}$ is $(-1)^k$ times the usual orientation. The reason for such a choice will become clear in the next section.

If M is an *oriented* $(n - 1)$ -dimensional manifold in \mathbf{R}^n , a substitute for outward unit normal vectors can be defined,

FIGURE 5-8. Some outward unit normal vectors of manifolds-with-boundary in \mathbf{R}^3 .

even though M is not necessarily the boundary of an n -dimensional manifold. If $[v_1, \dots, v_{n-1}] = \mu_x$, we choose $n(x)$ in \mathbf{R}^n_x so that $n(x)$ is a unit vector perpendicular to M_x and $[n(x), v_1, \dots, v_{n-1}]$ is the usual orientation of \mathbf{R}^n_x . We still call $n(x)$ the outward unit normal to M (determined by μ). The vectors $n(x)$ vary continuously on M , in an obvious sense. Conversely, if a continuous family of unit normal vectors $n(x)$ is defined on all of M , then we can determine an orientation of M . This shows that such a continuous choice of normal vectors is impossible on the Möbius strip. In the paper model of the Möbius strip the two sides of the paper (which has thickness) may be thought of as the end points of the unit

normal vectors in both directions. The impossibility of choosing normal vectors continuously is reflected by the famous property of the paper model. The paper model is one-sided (if you start to paint it on one side you end up painting it all over); in other words, choosing $n(x)$ arbitrarily at one point, and then by the continuity requirement at other points, eventually forces the opposite choice for $n(x)$ at the initial point.

Problems. 5-9. Show that M_x consists of the tangent vectors at t of curves c in M with $c(t) = x$.

5-10. Suppose \mathcal{C} is a collection of coordinate systems for M such that (1) For each $x \in M$ there is $f \in \mathcal{C}$ which is a coordinate system around x ; (2) if $f, g \in \mathcal{C}$, then $\det(f^{-1} \circ g)' > 0$. Show that there is a unique orientation of M such that f is orientation-preserving if $f \in \mathcal{C}$.

5-11. If M is an n -dimensional manifold-with-boundary in \mathbf{R}^n , define μ_x as the usual orientation of $M_x = \mathbf{R}^n_x$ (the orientation μ so defined is the **usual orientation** of M). If $x \in \partial M$, show that the two definitions of $n(x)$ given above agree.

5-12. (a) If F is a differentiable vector field on $M \subset \mathbf{R}^n$, show that there is an open set $A \supset M$ and a differentiable vector field \tilde{F} on A with $\tilde{F}(x) = F(x)$ for $x \in M$. *Hint:* Do this locally and use partitions of unity.

(b) If M is closed, show that we can choose $A = \mathbf{R}^n$.

5-13. Let $g: A \rightarrow \mathbf{R}^p$ be as in Theorem 5-1.

(a) If $x \in M = g^{-1}(0)$, let $h: U \rightarrow \mathbf{R}^n$ be the essentially unique diffeomorphism such that $g \circ h(y) = (y^{n-p+1}, \dots, y^n)$ and $h(0) = x$. Define $f: \mathbf{R}^{n-p} \rightarrow \mathbf{R}^n$ by $f(a) = h(0, a)$. Show that f_* is 1-1 so that the $n - p$ vectors $f_*((e_1)_0), \dots, f_*((e_{n-p})_0)$ are linearly independent.

(b) Show that orientations μ_x can be defined consistently, so that M is orientable.

(c) If $p = 1$, show that the components of the outward normal at x are some multiple of $D_1g(x), \dots, D_n g(x)$.

5-14. If $M \subset \mathbf{R}^n$ is an orientable $(n - 1)$ -dimensional manifold, show that there is an open set $A \subset \mathbf{R}^n$ and a differentiable $g: A \rightarrow \mathbf{R}^1$ so that $M = g^{-1}(0)$ and $g'(x)$ has rank 1 for $x \in M$. *Hint:* Problem 5-4 does this locally. Use the orientation to choose consistent local solutions and use partitions of unity.

5-15. Let M be an $(n - 1)$ -dimensional manifold in \mathbf{R}^n . Let $M(\epsilon)$ be the set of end points of normal vectors (in both directions) of length ϵ and suppose ϵ is small enough so that $M(\epsilon)$ is also an

$(n - 1)$ -dimensional manifold. Show that $M(\epsilon)$ is orientable (even if M is not). What is $M(\epsilon)$ if M is the Möbius strip?

- 5-16. Let $g: A \rightarrow \mathbf{R}^p$ be as in Theorem 5-1. If $f: \mathbf{R}^n \rightarrow \mathbf{R}$ is differentiable and the maximum (or minimum) of f on $g^{-1}(0)$ occurs at a , show that there are $\lambda_1, \dots, \lambda_p \in \mathbf{R}$, such that

$$(1) \quad D_j f(a) = \sum_{i=1}^n \lambda_i D_j g^i(a) \quad j = 1, \dots, n.$$

Hint: This equation can be written $df(a) = \sum_{i=1}^n \lambda_i dg^i(a)$ and is obvious if $g(x) = (x^{n-p+1}, \dots, x^n)$.

The maximum of f on $g^{-1}(0)$ is sometimes called the maximum of f subject to the **constraints** $g^i = 0$. One can attempt to find a by solving the system of equations (1). In particular, if $g: A \rightarrow \mathbf{R}$, we must solve $n + 1$ equations

$$\begin{aligned} D_j f(a) &= \lambda D_j g(a), \\ g(a) &= 0, \end{aligned}$$

in $n + 1$ unknowns a^1, \dots, a^n, λ , which is often very simple if we leave the equation $g(a) = 0$ for last. This is **Lagrange's method**, and the useful but irrelevant λ is called a **Lagrangian multiplier**. The following problem gives a nice theoretical use for Lagrangian multipliers.

- 5-17. (a) Let $T: \mathbf{R}^n \rightarrow \mathbf{R}^n$ be self-adjoint with matrix $A = (a_{ij})$, so that $a_{ij} = a_{ji}$. If $f(x) = \langle Tx, x \rangle = \sum a_{ij} x^i x^j$, show that $D_k f(x) = 2 \sum_{j=1}^n a_{kj} x^j$. By considering the maximum of $\langle Tx, x \rangle$ on S^{n-1} show that there is $x \in S^{n-1}$ and $\lambda \in \mathbf{R}$ with $Tx = \lambda x$.
 (b) If $V = \{y \in \mathbf{R}^n: \langle x, y \rangle = 0\}$, show that $T(V) \subset V$ and $T: V \rightarrow V$ is self-adjoint.
 (c) Show that T has a basis of eigenvectors.

STOKES' THEOREM ON MANIFOLDS

If ω is a p -form on a k -dimensional manifold-with-boundary M and c is a singular p -cube in M , we define

$$\int_c \omega = \int_{[0,1]^p} c^* \omega$$

precisely as before; integrals over p -chains are also defined as before. In the case $p = k$ it may happen that there is an open set $W \supset [0,1]^k$ and a coordinate system $f: W \rightarrow \mathbf{R}^n$ such that $c(x) = f(x)$ for $x \in [0,1]^k$; a k -cube in M will always be

understood to be of this type. If M is oriented, the singular k -cube c is called **orientation-preserving** if f is.

5-4 Theorem. *If $c_1, c_2: [0,1]^k \rightarrow M$ are two orientation-preserving singular k -cubes in the oriented k -dimensional manifold M and ω is a k -form on M such that $\omega = 0$ outside of $c_1([0,1]^k) \cap c_2([0,1]^k)$, then*

$$\int_{c_1} \omega = \int_{c_2} \omega.$$

Proof. We have

$$\int_{c_1} \omega = \int_{[0,1]^k} c_1^*(\omega) = \int_{[0,1]^k} (c_2^{-1} \circ c_1)^* c_2^*(\omega).$$

(Here $c_2^{-1} \circ c_1$ is defined only on a subset of $[0,1]^k$ and the second equality depends on the fact that $\omega = 0$ outside of $c_1([0,1]^k) \cap c_2([0,1]^k)$.) It therefore suffices to show that

$$\int_{[0,1]^k} (c_2^{-1} \circ c_1)^* c_2^*(\omega) = \int_{[0,1]^k} c_2^*(\omega) = \int_{c_2} \omega.$$

If $c_2^*(\omega) = f dx^1 \wedge \cdots \wedge dx^k$ and $c_2^{-1} \circ c_1$ is denoted by g , then by Theorem 4-9 we have

$$\begin{aligned} (c_2^{-1} \circ c_1)^* c_2^*(\omega) &= g^*(f dx^1 \wedge \cdots \wedge dx^k) \\ &= (f \circ g) \cdot \det g' \cdot dx^1 \wedge \cdots \wedge dx^k \\ &= (f \circ g) \cdot |\det g'| \cdot dx^1 \wedge \cdots \wedge dx^k, \end{aligned}$$

since $\det g' = \det(c_2^{-1} \circ c_1)' > 0$. The result now follows from Theorem 3-13. ■

The last equation in this proof should help explain why we have had to be so careful about orientations.

Let ω be a k -form on an oriented k -dimensional manifold M . If there is an orientation-preserving singular k -cube c in M such that $\omega = 0$ outside of $c([0,1]^k)$, we define

$$\int_M \omega = \int_c \omega.$$

Theorem 5-4 shows $\int_M \omega$ does not depend on the choice of c .

Suppose now that ω is an arbitrary k -form on M . There is an open cover \mathcal{O} of M such that for each $U \in \mathcal{O}$ there is an orientation-preserving singular k -cube c with $U \subset c([0,1]^k)$. Let Φ be a partition of unity for M subordinate to this cover. We define

$$\int_M \omega = \sum_{\varphi \in \Phi} \int_M \varphi \cdot \omega$$

provided the sum converges as described in the discussion preceding Theorem 3-12 (this is certainly true if M is compact). An argument similar to that in Theorem 3-12 shows that $\int_M \omega$ does not depend on the cover \mathcal{O} or on Φ .

All our definitions could have been given for a k -dimensional manifold-with-boundary M with orientation μ . Let ∂M have the induced orientation $\partial\mu$. Let c be an orientation-preserving k -cube in M such that $c_{(k,0)}$ lies in ∂M and is the only face which has any interior points in ∂M . As the remarks after the definition of $\partial\mu$ show, $c_{(k,0)}$ is orientation-preserving if k is even, but not if k is odd. Thus, if ω is a $(k-1)$ -form on M which is 0 outside of $c([0,1]^k)$, we have

$$\int_{c_{(k,0)}} \omega = (-1)^k \int_{\partial M} \omega.$$

On the other hand, $c_{(k,0)}$ appears with coefficient $(-1)^k$ in ∂c . Therefore

$$\int_{\partial c} \omega = \int_{(-1)^k c_{(k,0)}} \omega = (-1)^k \int_{c_{(k,0)}} \omega = \int_{\partial M} \omega.$$

Our choice of $\partial\mu$ was made to eliminate any minus signs in this equation, and in the following theorem.

5-5 Theorem (Stokes' Theorem). *If M is a compact oriented k -dimensional manifold-with-boundary and ω is a $(k-1)$ -form on M , then*

$$\int_M d\omega = \int_{\partial M} \omega.$$

(Here ∂M is given the induced orientation.)

Proof. Suppose first that there is an orientation-preserving singular k -cube in $M - \partial M$ such that $\omega = 0$ outside of

$c([0,1]^k)$. By Theorem 4-13 and the definition of $d\omega$ we have

$$\int_c d\omega = \int_{[0,1]^k} c^*(d\omega) = \int_{[0,1]^k} d(c^*\omega) = \int_{\partial I^k} c^*\omega = \int_{\partial c} \omega.$$

Then

$$\int_M d\omega = \int_c d\omega = \int_{\partial c} \omega = 0,$$

since $\omega = 0$ on ∂c . On the other hand, $\int_{\partial M} \omega = 0$ since $\omega = 0$ on ∂M .

Suppose next that there is an orientation-preserving singular k -cube in M such that $c_{(k,0)}$ is the only face in ∂M , and $\omega = 0$ outside of $c([0,1]^k)$. Then

$$\int_M d\omega = \int_c d\omega = \int_{\partial c} \omega = \int_{\partial M} \omega.$$

Now consider the general case. There is an open cover \mathcal{O} of M and a partition of unity Φ for M subordinate to \mathcal{O} such that for each $\varphi \in \Phi$ the form $\varphi \cdot \omega$ is of one of the two sorts already considered. We have

$$0 = d(1) = d\left(\sum_{\varphi \in \Phi} \varphi\right) = \sum_{\varphi \in \Phi} d\varphi,$$

so that

$$\sum_{\varphi \in \Phi} d\varphi \wedge \omega = 0.$$

Since M is compact, this is a finite sum and we have

$$\sum_{\varphi \in \Phi} \int_M d\varphi \wedge \omega = 0.$$

Therefore

$$\begin{aligned} \int_M d\omega &= \sum_{\varphi \in \Phi} \int_M \varphi \cdot d\omega = \sum_{\varphi \in \Phi} \int_M d\varphi \wedge \omega + \varphi \cdot d\omega \\ &= \sum_{\varphi \in \Phi} \int_M d(\varphi \cdot \omega) = \sum_{\varphi \in \Phi} \int_{\partial M} \varphi \cdot \omega \\ &= \int_{\partial M} \omega. \quad \blacksquare \end{aligned}$$

Problems. 5-18. If M is an n -dimensional manifold (or manifold-with-boundary) in \mathbf{R}^n , with the usual orientation, show that

$\int_M f dx^1 \wedge \cdots \wedge dx^n$, as defined in this section, is the same as $\int_M f$, as defined in Chapter 3.

5-19. (a) Show that Theorem 5-5 is false if M is not compact. *Hint:* If M is a manifold-with-boundary for which 5-5 holds, then $M - \partial M$ is also a manifold-with-boundary (with empty boundary).

(b) Show that Theorem 5-5 holds for noncompact M provided that ω vanishes outside of a compact subset of M .

5-20. If ω is a $(k-1)$ -form on a compact k -dimensional manifold M , prove that $\int_M d\omega = 0$. Give a counterexample if M is not compact.

5-21. An **absolute k -tensor** on V is a function $\eta: V^k \rightarrow \mathbf{R}$ of the form $|\omega|$ for $\omega \in \Lambda^k(V)$. An **absolute k -form** on M is a function η such that $\eta(x)$ is an absolute k -tensor on M_x . Show that $\int_M \eta$ can be defined, even if M is not orientable.

5-22. If $M_1 \subset \mathbf{R}^n$ is an n -dimensional manifold-with-boundary and $M_2 \subset M_1 - \partial M_1$ is an n -dimensional manifold-with-boundary, and M_1, M_2 are compact, prove that

$$\int_{\partial M_1} \omega = \int_{\partial M_2} \omega,$$

where ω is an $(n-1)$ -form on M_1 , and ∂M_1 and ∂M_2 have the orientations induced by the usual orientations of M_1 and M_2 . *Hint:* Find a manifold-with-boundary M such that $\partial M = \partial M_1 \cup \partial M_2$ and such that the induced orientation on ∂M agrees with that for ∂M_1 on ∂M_1 and is the negative of that for ∂M_2 on ∂M_2 .

THE VOLUME ELEMENT

Let M be a k -dimensional manifold (or manifold-with-boundary) in \mathbf{R}^n , with an orientation μ . If $x \in M$, then μ_x and the inner product T_x we defined previously determine a volume element $\omega(x) \in \Lambda^k(M_x)$. We therefore obtain a nowhere-zero k -form ω on M , which is called the **volume element** on M (determined by μ) and denoted dV , even though it is not generally the differential of a $(k-1)$ -form. The **volume** of M is defined as $\int_M dV$, provided this integral exists, which is certainly the case if M is compact. "Volume" is usually called **length** or **surface area** for one- and two-dimensional manifolds, and dV is denoted ds (the "element of length") or dA [or dS] (the "element of [surface] area").

A concrete case of interest to us is the volume element of an

oriented surface (two-dimensional manifold) M in \mathbf{R}^3 . Let $n(x)$ be the unit outward normal at $x \in M$. If $\omega \in \Lambda^2(M_x)$ is defined by

$$\omega(v, w) = \det \begin{pmatrix} v \\ w \\ n(x) \end{pmatrix},$$

then $\omega(v, w) = 1$ if v and w are an orthonormal basis of M_x with $[v, w] = \mu_x$. Thus $dA = \omega$. On the other hand, $\omega(v, w) = \langle v \times w, n(x) \rangle$ by definition of $v \times w$. Thus we have

$$dA(v, w) = \langle v \times w, n(x) \rangle.$$

Since $v \times w$ is a multiple of $n(x)$ for $v, w \in M_x$, we conclude that

$$dA(v, w) = |v \times w|$$

if $[v, w] = \mu_x$. If we wish to compute the area of M , we must evaluate $\int_{[0,1]^2} c^*(dA)$ for orientation-preserving singular 2-cubes c . Define

$$E(a) = [D_1 c^1(a)]^2 + [D_1 c^2(a)]^2 + [D_1 c^3(a)]^2,$$

$$\begin{aligned} F(a) = & D_1 c^1(a) \cdot D_2 c^1(a) \\ & + D_1 c^2(a) \cdot D_2 c^2(a) \\ & + D_1 c^3(a) \cdot D_2 c^3(a), \end{aligned}$$

$$G(a) = [D_2 c^1(a)]^2 + [D_2 c^2(a)]^2 + [D_2 c^3(a)]^2.$$

Then

$$\begin{aligned} c^*(dA)((e_1)_a, (e_2)_a) &= dA(c_*((e_1)_a), c_*((e_2)_a)) \\ &= |(D_1 c^1(a), D_1 c^2(a), D_1 c^3(a)) \times (D_2 c^1(a), D_2 c^2(a), D_2 c^3(a))| \\ &= \sqrt{E(a)G(a) - F(a)^2} \end{aligned}$$

by Problem 4-9. Thus

$$\int_{[0,1]^2} c^*(dA) = \int_{[0,1]^2} \sqrt{EG - F^2}.$$

Calculating surface area is clearly a foolhardy enterprise; fortunately one seldom needs to know the area of a surface. Moreover, there is a simple expression for dA which suffices for theoretical considerations.

5-6 Theorem. *Let M be an oriented two-dimensional manifold (or manifold-with-boundary) in \mathbf{R}^3 and let n be the unit outward normal. Then*

$$(1) \quad dA = n^1 dy \wedge dz + n^2 dz \wedge dx + n^3 dx \wedge dy.$$

Moreover, on M we have

$$(2) \quad n^1 dA = dy \wedge dz.$$

$$(3) \quad n^2 dA = dz \wedge dx.$$

$$(4) \quad n^3 dA = dx \wedge dy.$$

Proof.

Equation (1) is equivalent to the equation

$$dA(v, w) = \det \begin{pmatrix} v \\ w \\ n(x) \end{pmatrix}.$$

This is seen by expanding the determinant by minors along the bottom row. To prove the other equations, let $z \in \mathbf{R}^3_x$. Since $v \times w = \alpha n(x)$ for some $\alpha \in \mathbf{R}$, we have

$$\langle z, n(x) \rangle \cdot \langle v \times w, n(x) \rangle = \langle z, n(x) \rangle \alpha = \langle z, \alpha n(x) \rangle = \langle z, v \times w \rangle.$$

Choosing $z = e_1, e_2$, and e_3 we obtain (2), (3), and (4). ■

A word of caution: if $\omega \in \Lambda^2(\mathbf{R}^3_a)$ is defined by

$$\begin{aligned} \omega &= n^1(a) \cdot dy(a) \wedge dz(a) \\ &\quad + n^2(a) \cdot dz(a) \wedge dx(a) \\ &\quad + n^3(a) \cdot dx(a) \wedge dy(a), \end{aligned}$$

it is *not* true, for example, that

$$n^1(a) \cdot \omega = dy(a) \wedge dz(a).$$

The two sides give the same result only when applied to $v, w \in M_a$.

A few remarks should be made to justify the definition of length and surface area we have given. If $c: [0, 1] \rightarrow \mathbf{R}^n$ is differentiable and $c([0, 1])$ is a one-dimensional manifold-with-boundary, it can be shown, but the proof is messy, that the length of $c([0, 1])$ is indeed the least upper bound of the lengths

FIGURE 5-9. A surface containing 20 triangles inscribed in a portion of a cylinder. If the number of triangles is increased sufficiently, by making the bases of triangles 3, 4, 7, 8, etc., sufficiently small, the total area of the inscribed surface can be made as large as desired.

of inscribed broken lines. If $c: [0,1]^2 \rightarrow \mathbf{R}^n$, one naturally hopes that the area of $c([0,1]^2)$ will be the least upper bound of the areas of surfaces made up of triangles whose vertices lie in $c([0,1]^2)$. Amazingly enough, such a least upper bound is usually nonexistent—one can find inscribed polygonal surfaces arbitrarily close to $c([0,1]^2)$ with arbitrarily large area! This is indicated for a cylinder in Figure 5-9. Many definitions of surface area have been proposed, disagreeing with each other, but all agreeing with our definition for differentiable surfaces. For a discussion of these difficult questions the reader is referred to References [3] or [15].

Problems. 5-23. If M is an oriented one-dimensional manifold in \mathbf{R}^n and $c: [0,1] \rightarrow M$ is orientation-preserving, show that

$$\int_{[0,1]} c^*(ds) = \int_{[0,1]} \sqrt{[(c^1)']^2 + \cdots + [(c^n)']^2}.$$

- 5-24.** If M is an n -dimensional manifold in \mathbf{R}^n , with the usual orientation, show that $dV = dx^1 \wedge \cdots \wedge dx^n$, so that the volume of M , as defined in this section, is the volume as defined in Chapter 3. (Note that this depends on the numerical factor in the definition of $\omega \wedge \eta$.)
- 5-25.** Generalize Theorem 5-6 to the case of an oriented $(n - 1)$ -dimensional manifold in \mathbf{R}^n .
- 5-26.** (a) If $f: [a,b] \rightarrow \mathbf{R}$ is non-negative and the graph of f in the xy -plane is revolved around the x -axis in \mathbf{R}^3 to yield a surface M , show that the area of M is

$$\int_a^b 2\pi f \sqrt{1 + (f')^2}.$$

(b) Compute the area of S^2 .

- 5-27.** If $T: \mathbf{R}^n \rightarrow \mathbf{R}^n$ is a norm preserving linear transformation and M is a k -dimensional manifold in \mathbf{R}^n , show that M has the same volume as $T(M)$.
- 5-28.** (a) If M is a k -dimensional manifold, show that an absolute k -tensor $|dV|$ can be defined, even if M is not orientable, so that the volume of M can be defined as $\int_M |dV|$.
- (b) If $c: [0,2\pi] \times (-1,1) \rightarrow \mathbf{R}^3$ is defined by $c(u,v) =$
- $$(2 \cos u + v \sin(u/2) \cos u, 2 \sin u + v \sin(u/2) \sin u, v \cos u/2),$$
- show that $c([0,2\pi] \times (-1,1))$ is a Möbius strip and find its area.

- 5-29. If there is a nowhere-zero k -form on a k -dimensional manifold M , show that M is orientable.
- 5-30. (a) If $f: [0,1] \rightarrow \mathbf{R}$ is differentiable and $c: [0,1] \rightarrow \mathbf{R}^2$ is defined by $c(x) = (x, f(x))$, show that $c([0,1])$ has length $\int_0^1 \sqrt{1 + (f')^2}$.
 (b) Show that this length is the least upper bound of lengths of inscribed broken lines. *Hint:* If $0 = t_0 \leq t_1 \leq \cdots \leq t_n = 1$, then

$$\begin{aligned} |c(t_i) - c(t_{i-1})| &= \sqrt{(t_i - t_{i-1})^2 + (f(t_i) - f(t_{i-1}))^2} \\ &= \sqrt{(t_i - t_{i-1})^2 + f'(s_i)^2 (t_i - t_{i-1})^2} \end{aligned}$$

for some $s_i \in [t_{i-1}, t_i]$.

- 5-31. Consider the 2-form ω defined on $\mathbf{R}^3 - 0$ by

$$\omega = \frac{x \, dy \wedge dz + y \, dz \wedge dx + z \, dx \wedge dy}{(x^2 + y^2 + z^2)^{\frac{3}{2}}}.$$

- (a) Show that ω is closed.
 (b) Show that

$$\omega(p)(v_p, w_p) = \frac{\langle v \times w, p \rangle}{|p|^3}.$$

For $r > 0$ let $S^2(r) = \{x \in \mathbf{R}^3: |x| = r\}$. Show that ω restricted to the tangent space of $S^2(r)$ is $1/r^2$ times the volume element, and that $\int_{S^2(r)} \omega = 4\pi$. Conclude that ω is not exact. Nevertheless we denote ω by $d\theta$ since, as we shall see, $d\theta$ is the analogue of the 1-form $d\theta$ on $\mathbf{R}^2 - 0$.

(c) If v_p is a tangent vector such that $v = \lambda p$ for some $\lambda \in \mathbf{R}$ show that $d\theta(p)(v_p, w_p) = 0$ for all w_p . If a two-dimensional manifold M in \mathbf{R}^3 is part of a generalized cone, that is, M is the union of segments of rays through the origin, show that $\int_M d\theta = 0$.

(d) Let $M \subset \mathbf{R}^3 - 0$ be a compact two-dimensional manifold-with-boundary such that every ray through 0 intersects M at most once (Figure 5-10). The union of those rays through 0 which intersect M , is a solid cone $C(M)$. The **solid angle** subtended by M is defined as the area of $C(M) \cap S^2$, or equivalently as $1/r^2$ times the area of $C(M) \cap S^2(r)$ for $r > 0$. Prove that the solid angle subtended by M is $|\int_M d\theta|$. *Hint:* Choose r small enough so that there is a three-dimensional manifold-with-boundary N (as in Figure 5-10) such that ∂N is the union of M and $C(M) \cap S^2(r)$, and a part of a generalized cone. (Actually, N will be a manifold-with-corners; see the remarks at the end of the next section.)

(b) If $r(u,v) = |f(u) - g(v)|$ show that

$$l(f,g) = \frac{-1}{4\pi} \int_0^1 \int_0^1 \frac{1}{[r(u,v)]^3} \cdot A(u,v) \, du \, dv$$

where

$$A(u,v) = \det \begin{pmatrix} (f^1)'(u) & (f^2)'(u) & (f^3)'(u) \\ (g^1)'(v) & (g^2)'(v) & (g^3)'(v) \\ f^1(u) - g^1(v) & f^2(u) - g^2(v) & f^3(u) - g^3(v) \end{pmatrix}.$$

(c) Show that $l(f,g) = 0$ if f and g both lie in the xy -plane. The curves of Figure 4-5 (b) are given by $f(u) = (\cos u, \sin u, 0)$ and $g(v) = (1 + \cos v, 0, \sin v)$. You may easily convince yourself that calculating $l(f,g)$ by the above integral is hopeless in this case. The following problem shows how to find $l(f,g)$ without explicit calculations.

5-33. (a) If $(a,b,c) \in \mathbf{R}^3$ define

$$d\Theta_{(a,b,c)} = \frac{(x-a)dy \wedge dz + (y-b)dz \wedge dx + (z-c)dx \wedge dy}{[(x-a)^2 + (y-b)^2 + (z-c)^2]^{\frac{3}{2}}}.$$

If M is a compact two-dimensional manifold-with-boundary in \mathbf{R}^3 and $(a,b,c) \notin M$ define

$$\Omega(a,b,c) = \int_M d\Theta_{(a,b,c)}.$$

Let (a,b,c) be a point on the same side of M as the outward normal and (a',b',c') a point on the opposite side. Show that by choosing (a,b,c) sufficiently close to (a',b',c') we can make $\Omega(a,b,c) - \Omega(a',b',c')$ as close to -4π as desired. *Hint:* First show that if $M = \partial N$ then $\Omega(a,b,c) = -4\pi$ for $(a,b,c) \in N - M$ and $\Omega(a,b,c) = 0$ for $(a,b,c) \notin N$.

(b) Suppose $f([0,1]) = \partial M$ for some compact oriented two-dimensional manifold-with-boundary M . (If f does not intersect itself such an M always exists, even if f is knotted, see [6], page 138.) Suppose that whenever g intersects M at x the tangent vector v of g is not in M_x . Let n^+ be the number of intersections where v points in the same direction as the outward normal and n^- the number of other intersections. If $n = n^+ - n^-$ show that

$$n = \frac{-1}{4\pi} \int_g d\Omega.$$

(c) Prove that

$$\begin{aligned} D_1\Omega(a,b,c) &= \int_f \frac{(y-b)dz - (z-c)dy}{r^3} \\ D_2\Omega(a,b,c) &= \int_f \frac{(z-c)dx - (x-a)dz}{r^3} \\ D_3\Omega(a,b,c) &= \int_f \frac{(x-a)dy - (y-b)dx}{r^3}, \end{aligned}$$

where $r(x,y,z) = |(x,y,z)|$.

(d) Show that the integer n of (b) equals the integral of Problem 5-32(b), and use this result to show that $l(f,g) = 1$ if f and g are the curves of Figure 4-6 (b), while $l(f,g) = 0$ if f and g are the curves of Figure 4-6 (c). (These results were known to Gauss [7]. The proofs outlined here are from [4] pp. 409–411; see also [13], Volume 2, pp. 41–43.)

THE CLASSICAL THEOREMS

We have now prepared all the machinery necessary to state and prove the classical “Stokes’ type” of theorems. We will indulge in a little bit of self-explanatory classical notation.

5-7 Theorem (Green’s Theorem). *Let $M \subset \mathbf{R}^2$ be a compact two-dimensional manifold-with-boundary. Suppose that $\alpha, \beta: M \rightarrow \mathbf{R}$ are differentiable. Then*

$$\begin{aligned} \int_{\partial M} \alpha dx + \beta dy &= \int_M (D_1\beta - D_2\alpha) dx \wedge dy \\ &= \iint_M \left(\frac{\partial \beta}{\partial x} - \frac{\partial \alpha}{\partial y} \right) dx dy. \end{aligned}$$

(Here M is given the usual orientation, and ∂M the induced orientation, also known as the counterclockwise orientation.)

Proof. This is a very special case of Theorem 5-5, since $d(\alpha dx + \beta dy) = (D_1\beta - D_2\alpha) dx \wedge dy$. ■

5-8 Theorem (Divergence Theorem). Let $M \subset \mathbf{R}^3$ be a compact three-dimensional manifold-with-boundary and n the unit outward normal on ∂M . Let F be a differentiable vector field on M . Then

$$\int_M \operatorname{div} F \, dV = \int_{\partial M} \langle F, n \rangle \, dA.$$

This equation is also written in terms of three differentiable functions $\alpha, \beta, \gamma: M \rightarrow \mathbf{R}$:

$$\int_M \left(\frac{\partial \alpha}{\partial x} + \frac{\partial \beta}{\partial y} + \frac{\partial \gamma}{\partial z} \right) dV = \int_{\partial M} (n^1 \alpha + n^2 \beta + n^3 \gamma) \, dS.$$

Proof. Define ω on M by $\omega = F^1 dy \wedge dz + F^2 dz \wedge dx + F^3 dx \wedge dy$. Then $d\omega = \operatorname{div} F \, dV$. According to Theorem 5-6, on ∂M we have

$$\begin{aligned} n^1 dA &= dy \wedge dz, \\ n^2 dA &= dz \wedge dx, \\ n^3 dA &= dx \wedge dy. \end{aligned}$$

Therefore on ∂M we have

$$\begin{aligned} \langle F, n \rangle dA &= F^1 n^1 dA + F^2 n^2 dA + F^3 n^3 dA \\ &= F^1 dy \wedge dz + F^2 dz \wedge dx + F^3 dx \wedge dy \\ &= \omega. \end{aligned}$$

Thus, by Theorem 5-5 we have

$$\int_M \operatorname{div} F \, dV = \int_M d\omega = \int_{\partial M} \omega = \int_{\partial M} \langle F, n \rangle \, dA. \quad \blacksquare$$

5-9 Theorem (Stokes' Theorem). Let $M \subset \mathbf{R}^3$ be a compact oriented two-dimensional manifold-with-boundary and n the unit outward normal on M determined by the orientation of M . Let ∂M have the induced orientation. Let T be the vector field on ∂M with $ds(T) = 1$ and let F be a differentiable vector field in an open set containing M . Then

$$\int_M \langle (\nabla \times F), n \rangle \, dA = \int_{\partial M} \langle F, T \rangle \, ds.$$

This equation is sometimes written

$$\int_{\partial M} \alpha dx + \beta dy + \gamma dz = \iint_M \left[n^1 \left(\frac{\partial \gamma}{\partial y} - \frac{\partial \beta}{\partial z} \right) + n^2 \left(\frac{\partial \alpha}{\partial z} - \frac{\partial \gamma}{\partial x} \right) + n^3 \left(\frac{\partial \beta}{\partial x} - \frac{\partial \alpha}{\partial y} \right) \right] dS.$$

Proof. Define ω on M by $\omega = F^1 dx + F^2 dy + F^3 dz$. Since $\nabla \times F$ has components $D_2 F^3 - D_3 F^2$, $D_3 F^1 - D_1 F^3$, $D_1 F^2 - D_2 F^1$, it follows, as in the proof of Theorem 5-8, that on M we have

$$\begin{aligned} \langle (\nabla \times F), n \rangle dA &= (D_2 F^3 - D_3 F^2) dy \wedge dz \\ &\quad + (D_3 F^1 - D_1 F^3) dz \wedge dx \\ &\quad + (D_1 F^2 - D_2 F^1) dx \wedge dy \\ &= d\omega. \end{aligned}$$

On the other hand, since $ds(T) = 1$, on ∂M we have

$$\begin{aligned} T^1 ds &= dx, \\ T^2 ds &= dy, \\ T^3 ds &= dz. \end{aligned}$$

(These equations may be checked by applying both sides to T_x , for $x \in \partial M$, since T_x is a basis for $(\partial M)_x$.)

Therefore on ∂M we have

$$\begin{aligned} \langle F, T \rangle ds &= F^1 T^1 ds + F^2 T^2 ds + F^3 T^3 ds \\ &= F^1 dx + F^2 dy + F^3 dz \\ &= \omega. \end{aligned}$$

Thus, by Theorem 5-5, we have

$$\int_M \langle (\nabla \times F), n \rangle dA = \int_M d\omega = \int_{\partial M} \omega = \int_{\partial M} \langle F, T \rangle ds. \quad \blacksquare$$

Theorems 5-8 and 5-9 are the basis for the names $\operatorname{div} F$ and $\operatorname{curl} F$. If $F(x)$ is the velocity vector of a fluid at x (at some time) then $\int_{\partial M} \langle F, n \rangle dA$ is the amount of fluid “diverging” from M . Consequently the condition $\operatorname{div} F = 0$ expresses

the fact that the fluid is incompressible. If M is a disc, then $\int_{\partial M} \langle F, T \rangle ds$ measures the amount that the fluid curls around the center of the disc. If this is zero for all discs, then $\nabla \times F = 0$, and the fluid is called *irrotational*.

These interpretations of $\operatorname{div} F$ and $\operatorname{curl} F$ are due to Maxwell [13]. Maxwell actually worked with the negative of $\operatorname{div} F$, which he accordingly called the *convergence*. For $\nabla \times F$ Maxwell proposed "with great diffidence" the terminology *rotation of F*; this unfortunate term suggested the abbreviation $\operatorname{rot} F$ which one occasionally still sees.

The classical theorems of this section are usually stated in somewhat greater generality than they are here. For example, Green's Theorem is true for a square, and the Divergence Theorem is true for a cube. These two particular facts can be proved by approximating the square or cube by manifolds-with-boundary. A thorough generalization of the theorems of this section requires the concept of manifolds-with-corners; these are subsets of \mathbf{R}^n which are, up to diffeomorphism, locally a portion of \mathbf{R}^k which is bounded by pieces of $(k - 1)$ -planes. The ambitious reader will find it a challenging exercise to define manifolds-with-corners rigorously and to investigate how the results of this entire chapter may be generalized.

- Problems. 5-34.** Generalize the divergence theorem to the case of an n -manifold with boundary in \mathbf{R}^n .
- 5-35.** Applying the generalized divergence theorem to the set $M = \{x \in \mathbf{R}^n: |x| \leq a\}$ and $F(x) = x_x$, find the volume of $S^{n-1} = \{x \in \mathbf{R}^n: |x| = 1\}$ in terms of the n -dimensional volume of $B_n = \{x \in \mathbf{R}^n: |x| \leq 1\}$. (This volume is $\pi^{n/2}/(n/2)!$ if n is even and $2^{(n+1)/2}\pi^{(n-1)/2}/1 \cdot 3 \cdot 5 \cdot \dots \cdot n$ if n is odd.)
- 5-36.** Define F on \mathbf{R}^3 by $F(x) = (0, 0, cx^3)_x$ and let M be a compact three-dimensional manifold-with-boundary with $M \subset \{x: x^3 \leq 0\}$. The vector field F may be thought of as the downward pressure of a fluid of density c in $\{x: x^3 \leq 0\}$. Since a fluid exerts equal pressures in all directions, we define the *buoyant force* on M , due to the fluid, as $-\int_{\partial M} \langle F, n \rangle dA$. Prove the following theorem. *Theorem (Archimedes).* The buoyant force on M is equal to the weight of the fluid displaced by M .

Addenda

1. It should be remarked after Theorem 2-11 (the Inverse Function Theorem) that the formula for f^{-1} allows us to conclude that f^{-1} is actually continuously differentiable (and that it is C^∞ if f is). Indeed, it suffices to note that the entries of the inverse of a matrix A are C^∞ functions of the entries of A . This follows from "Cramer's Rule": $(A^{-1})_{ji} = (\det A^{ij})/(\det A)$, where A^{ij} is the matrix obtained from A by deleting row i and column j .

2. The proof of the first part of Theorem 3-8 can be simplified considerably, rendering Lemma 3-7 unnecessary. It suffices to cover B by the interiors of closed rectangles U_i with $\sum_{i=1}^\infty v(U_i) < \epsilon$, and to choose for each $x \in A - B$ a closed rectangle V_x , containing x in its interior, with $M_{V_x}(f) - m_{V_x}(f) < \epsilon$. If every subrectangle of a partition P is contained in one of some finite collection of U_i 's and V_x 's which cover A , and $|f(x)| \leq M$ for all x in A , then $U(f, P) - L(f, P) < \epsilon v(A) + 2M\epsilon$.

The proof of the converse part contains an error, since $M_s(f) - m_s(f) \geq 1/n$ is guaranteed only if the interior of S intersects $B_{1/n}$. To compensate for this it suffices to cover the boundaries of all subrectangles of P with a finite collection of rectangles with total volume $< \epsilon$. These, together with \mathcal{S} , cover $B_{1/n}$, and have total volume $< 2\epsilon$.

3. The argument in the first part of Theorem 3-14 (Sard's Theorem) requires a little amplification. If $U \subset A$ is a closed rectangle with sides of length l , then, because U is compact, there is an integer N with the following property: if U is divided into N^n rectangles, with sides of length l/N , then $|D_j g^i(w) - D_j g^i(z)| < \varepsilon/n^2$ whenever w and z are both in one such rectangle S . Given $x \in S$, let $f(z) = Dg(x)(z) - g(z)$. Then, if $z \in S$,

$$|D_j f^i(z)| = |D_j g^i(x) - D_j g^i(z)| < \varepsilon/n^2.$$

So by Lemma 2-10, if $x, y \in S$, then

$$\begin{aligned} |Dg(x)(y - x) - g(y) + g(x)| &= |f(y) - f(x)| < \varepsilon|x - y| \\ &\leq \varepsilon \sqrt{n} (l/N). \end{aligned}$$

4. Finally, the notation $\Lambda^k(V)$ appearing in this book is incorrect, since it conflicts with the standard definition of $\Lambda^k(V)$ (as a certain quotient of the tensor algebra of V). For the vector space in question (which is naturally isomorphic to $\Lambda^k(V^*)$ for finite dimensional vector spaces V) the notation $\Omega^k(V)$ is probably on the way to becoming standard. This substitution should be made on pages 78-85, 88-89, 116, and 126-128.
